Abstract

Background: Virtual reality (VR) has shown promising levels of effectiveness in nursing education, pain management, and rehabilitation. However, meta-analyses have discussed the effects of VR usage in nursing unilaterally and inconsistently, and the evidence base is diffuse and varied.

Objective: We aimed to synthesize the combined evidence from meta-analyses that assessed the effects of nurses using VR technology on nursing education or patient health outcomes.

Methods: We conducted an umbrella review by searching for meta-analyses about VR intervention in clinical nursing practice on Web of Science, Embase, Cochrane, and PubMed, and in reference lists. Eligible studies were published in English between December 1, 2012, and September 20, 2023. Meta-analyses of ≤2 intervention studies and meta-analyses without 95% CI or heterogeneity data were excluded. Characteristic indicators, population information, VR intervention information, and 95% CIs were extracted. A descriptive analysis of research results was conducted to discern relationships between VR interventions and outcomes. I^2 and *P* values were used to evaluate publication bias. AMSTAR (A Measurement Tool to Assess Systematic Reviews) 2 and the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) checklist were used to appraise literature quality.

Results: In total, 768 records were identified; 74 meta-analyses were included for review. The most reported VR study conditions were neuronursing (25/74, 34%), pediatric nursing (13/74, 18%), surgical and wound care (11/74, 15%), oncological nursing (11/74, 15%), and older adult nursing (10/74, 14%). Further, 30% (22/74) of meta-analyses reported publication bias, and 15% (11/74) and 8% (6/74) were rated as "high" based on AMSTAR 2 and the GRADE checklist, respectively. The main outcome indicators among all included meta-analyses were pain (37/214, 17.3%), anxiety (36/214, 16.8%), cognitive function (17/214, 7.9%), balance (16/214, 7.5%), depression (16/214, 7.5%), motor function (12/214, 5.6%), and participation in life (12/214, 5.6%). VR treatment for cognition, pain, anxiety, and depression was effective (all *P* values were <.05), while the utility of VR for improving motor function, balance, memory, and attention was controversial. Adverse effects included nausea, vomiting, and dizziness (incidence: range 4.76%-50%). The most common VR platforms were Pico VR glasses, head-mounted displays, the Nintendo Wii, and the Xbox Kinect. VR intervention duration ranged from 2 weeks to 12 months (typically ≥4 wk). VR session length and frequency ranged from 5 to 100 minutes and from 1 to 10 times per week, respectively.

Conclusions: VR in nursing has positive effects—relieving patients' pain, anxiety, and depression and improving cognitive function—despite the included studies' limited quality. However, applying VR in nursing to improve patients' motor function, balance, memory, and attention remains controversial. Nursing researchers need to further explore the effects and standard operation protocols of VR in clinical practice, and more high-quality research on VR in nursing is needed.

virtual reality; clinical nursing; artificial intelligence; AI-assisted medical rehabilitation; health promotion; umbrella review

Introduction

Virtual reality (VR) refers to an immersive digital technology that was first conceptualized in the 20th century [1,2] and involves using computer devices and hardware to interact with a specific artificial sensory environment. VR technology can create a standardized, safe, flexible, and virtual environment and provide real-time, strategic, and goal-directed feedback [3]. Because of these advantages, VR technology entered the medical field in 1993 [4]. More and more countries have introduced policies to promote the application of VR technology in the field of health care [5]. Evidence suggests that VR could be beneficial in enhancing the surgical abilities of physicians and minimizing errors during surgical procedures [6]. Additionally, some research indicates that VR may elicit neurophysiological changes, beyond basic distraction, that contribute to its efficacy for pain management [7,8]. The potential of VR indicates that there will be few areas of medicine that do not take advantage of this improved computer interface.

As popular equipment for health care assistance, VR technology plays an important role in the field of clinical nursing, and VR environments are ideally suited to the measurement of many variables of interest in clinical nursing practice. VR was first used by nurses in the field of clinical rehabilitation nursing and gradually became extensively used in the fields of neurological disease, cancer, and wound care [9-11]. Several studies indicate that VR rehabilitation training is more effective among patients with Parkinson disease, especially in improving gait and balance ability [12,13]. VR can also be used as a distraction from pain and anxiety among pediatric patients and patients with cancer. Mohammad and Ahmad [14] found that immersive VR is an effective distraction intervention for managing pain and anxiety among patients with breast cancer. It is also reported that using immersive VR as an auxiliary intervention is more effective than using morphine alone in relieving pain and anxiety [15]. Moreover, the use of VR technology may be an effective, auxiliary, nondrug method for managing kinesiophobia [16].

Although it has been shown in various publications that VR has the potential to help in clinical nursing practice, there remain controversies on the functions, effects, and intervention protocols of VR application in clinical nursing. In addition, the results of multiple meta-analyses that discussed VR intervention effects in different patients are inconsistent [17-19]. Further, the methodological limitations of current evidence impede definitive conclusions regarding the superiority of VR interventions over conventional approaches. A meta-analysis that examined the effect of VR training on patients' participation noted uncertainty regarding evident publication bias [2], indicating that conclusions regarding the superiority of VR should be made cautiously. Researchers believe that further rigorous research is required to engender robust evidence substantiating the prospective benefits of VR technology [20].

Umbrella reviews can evaluate the strength of the evidence from existing meta-analyses. An umbrella review integrates data and evaluates information on all clinical outcomes, and it can be used to provide a thorough, high-level summary of the evidence landscape for VR application in clinical nursing practice [21].

Given the background presented herein, we performed an umbrella review in which we synthesized and appraised evidence from selected meta-analyses to generate robust conclusions regarding the state of the literature.

Methods

Study Design

An umbrella review of meta-analyses was carried out according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) reporting guidelines, as described in Checklists 1 and 2. The research questions used to guide this umbrella review were as follows:

1. What is the current scope and extent of VR technology integration in clinical nursing practice?
2. For which clinical nursing issues has VR been principally used as an intervention, and what evidence exists regarding the efficacy and safety of VR in these contexts?
3. What are the primary barriers impeding the broader adoption of VR in clinical nursing settings, and what are the future research directions that may facilitate expanded VR application in nursing practice?

Inclusion and Exclusion Criteria

The eligibility criteria were as follows: studies that used a meta-analytic method, meta-analyses about VR intervention in clinical nursing practice, and meta-analyses published in English. The exclusion criteria were as follows: meta-analyses that collected ≤2 intervention studies and meta-analyses that had no 95% CI and heterogeneity data.

Search Strategy

We conducted the umbrella review by searching Web of Science, Embase (Ovid), Cochrane Library, PubMed, and relevant reference lists. Eligible studies were published between December 1, 2012, and September 1, 2023. The searches were rerun on September 20, 2023, to identify any recent publications. We reran the searches before the submission of this paper, and no extra literature was found. We searched for publications that included the following terms (including variations of these terms) in the title, abstract, and keywords list: *virtual reality*, *VR*, *virtual environment*, *immersive*, *nursing*, *care*, *meta-analysis*, and *review*. We also searched the reference lists of the most recent systematic reviews and meta-analyses. The literature retrieval strategy is shown in Multimedia Appendix 1.

Data Extraction and Collection

One researcher conducted the electronic database searches, eliminated duplicates and titles that were clearly outside the scope of the umbrella review, and then uploaded the remaining citations to NoteExpress version 3.7.09258 (Aegean Software Corp). Two reviewers independently examined the remaining full-text articles to identify those that met the inclusion and exclusion criteria. If there were multiple meta-analyses with the same research objectives and outcome indicators, the one with the highest quality score was selected. Any disagreements were resolved through discussion with a third reviewer.

Data were extracted and managed independently by 2 reviewers using a predefined extraction form. Any concerns were discussed with a third reviewer.

The following data were extracted: (1) characteristic indicators of meta-analyses (first author, year of publication, study design, study period, and number of component primary studies); (2) characteristics of primary studies (trial design, number of participants, and sectionalization); (3) population information (diagnosis and sample size); (4) VR intervention information (VR platform, population, and intervention course); and (5) statistical summaries (outcomes and effect measures with 95% CIs and heterogeneity).

Data Analysis

We did not reanalyze the other data or primary studies included in the meta-analyses because of the clinical and statistical heterogeneity between the study objectives and outcome indicators of the meta-analyses, and many of the articles did not provide the original data of the original clinical studies. As a result, a descriptive analysis was conducted to encapsulate the impact of VR on clinical nursing practice over the past decade. The process of executing this descriptive analysis involved presenting research results, such as participant details, outcomes, sample sizes, and study designs. These data were meticulously extracted into a predefined Excel (Microsoft Corp) form by YH and XY. Following this, the two authors conducted a thorough review and verification of the collected data to ensure their accuracy and reliability. In instances of disagreement, a consensus was achieved through discussion. In particular, the theme—discerning the relationships between VR interventions and patient outcomes—was summarized.

Quality Evaluation of Included Literature

AMSTAR (A Measurement Tool to Assess Systematic Reviews) 2 [22] and the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) checklist [23] were used to independently evaluate the methodological quality of the selected meta-analyses. Two researchers separately evaluated the evidence strength of meta-analyses. If there was disagreement, another researcher was asked to make a judgment.

We reviewed the full texts and supplementary materials of included meta-analyses. Two researchers extracted the estimated pooled effect and heterogeneity of each outcome reported in the meta-analyses. The estimated pooled effect, along with its 95% CI, for each included meta-analysis was extracted. We used the I^2 metric to assess heterogeneity (<25%: might show no heterogeneity; 25%-50%: might show moderate heterogeneity; 50%-75%: might show substantial heterogeneity; 75%-100%: considerable heterogeneity), and heterogeneity and *P* values (significant at $P<.05$) were used to assess publication bias.

Ethical Considerations

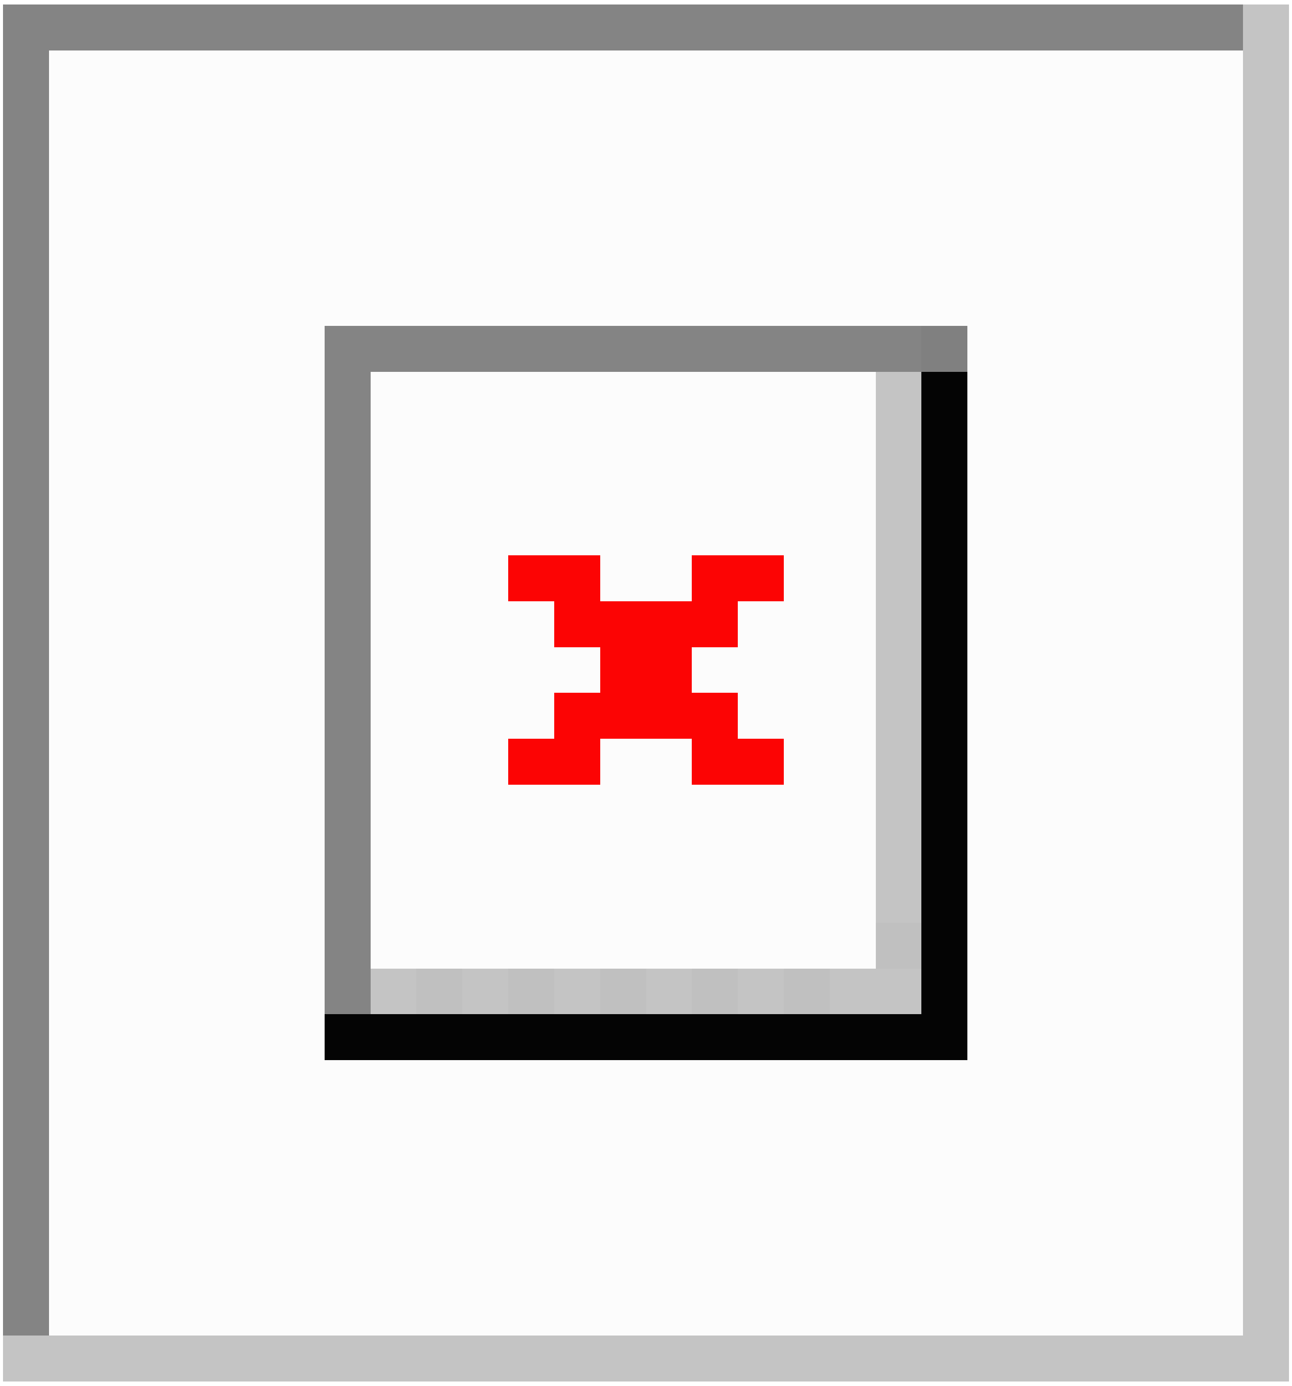
The protocol for this umbrella review was originally registered with PROSPERO in December 2022 (registration number: CRD42022381382). No ethical approval was needed, as we used data from published studies.

Results

Study Selection

The electronic literature search identified 768 records from 4 databases and the reference lists of included reviews. We screened the titles and abstracts of 634 records after removing 134 duplicate records. A total of 260 reviews remained after the titles and abstracts were screened for inclusion against predefined criteria. After reading the full texts, 74 articles were finally selected. Further details can be found in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for the search and selection of the eligible studies included in the umbrella review. Studies were identified via databases and registers. VR: virtual reality.



Basic Features of Included Studies

The included meta-analyses were meta-analyses of randomized controlled trials (RCTs), cross-over studies, pre-post studies, interrupted time series studies, quasi-controlled trials, case reports, controlled trials, or controlled clinical trials, and details of all included meta-analyses are listed in Tables 1 and 2.

Table . Characteristics of all included meta-analyses.

[e]ROM: range of motion.

[f]QOL: quality of life.

[g]MBI: modified Barthel Index.

Among all included meta-analyses, the most common participant groups investigated were neuronursing (25/74, 34%), pediatric nursing (13/74, 18%), surgical and wound care (11/74, 15%), oncological nursing (11/74, 15%), and older adult nursing (10/74, 14%) populations. The number of participants in each meta-analysis ranged from 103 to 3540, and 214 outcome indicators were found. The main outcome indicators in all included meta-analyses were pain (37/214, 17.3%), anxiety (36/214, 16.8%), cognitive function (17/214, 7.9%), balance (16/214, 7.5%), depression (16/214, 7.5%), motor function (12/214, 5.6%), and participation in life (12/214, 5.6%), among others. The distribution of populations and outcome indicators of VR application in nursing is shown in Multimedia Appendix 2.

Quality of Included Reviews

Publication Bias

With regard to publication bias, 30% (22/74) of meta-analyses reported publication bias, 23% (17/74) had no publication bias, and 47% (35/74) did not have such data available. Specific data are shown in Tables 1 and 2.

GRADE Classification and AMSTAR 2 Score

The meta-analyses were classified into 4 levels, with approximately 15% (11/74) rated as "high," approximately 28% (21/74) rated as "moderate," approximately 39% (29/74) rated as "low," and approximately 18% (13/74) rated as "very low" via AMSTAR 2. The main reasons for lower ratings were that many meta-analyses neither evaluated publication bias nor drafted research protocols in advance, and only a few meta-analyses reported the sources of funding for the studies included in the analysis. Approximately 49% (36/74) of meta-analyses were rated as "very low," approximately 34% (25/74) were rated as "low," approximately 9% (7/74) were rated as "moderate," and approximately 8% (6/74) were rated as "high" via the GRADE system. The detailed results of the AMSTAR 2 and GRADE evaluations are presented in Multimedia Appendices 3 and 4.

VR Application in Clinical Nursing Practice

VR in Neuronursing

A total of 25 articles focused on the effectiveness of VR in neurological nursing. These studies mainly concentrated on motor function, cognition, depression, participation in life, and quality of life. Of these studies, 18 included RCTs. The results showed that VR intervention for cognitive function [61] and depression [51] was effective (*P*<.05). However, its efficacy for motor function, participation in life, and quality of life was controversial. Chan et al [59] reported that VR training was more effective than traditional rehabilitation training in improving balance function (standardized mean difference [SMD] 0.22, 95% CI 0.01-0.42; *P*=.04) and mobility (mean difference −1.95, 95% CI −2.81 to –1.08; *P*<.01), while a study by Parra et al [79] showed that no statistical differences were found in balance and gait between patients with Parkinson disease in the VR group and those in the control group (odds ratio 0.83, 95% CI 0.62-1.12). The differences between meta-analyses were probably the result of the different heterogeneous populations or the interventions being used at different points in the disease course. Heterogeneity was low for depression and cognitive function (range 0.01-0.24).

VR in Pediatric Nursing

A total of 13 meta-analyses focused on children and were mainly about nursing for pain, anxiety, and fear. The results of these meta-analysis studies showed that VR technology intervention by nurses to reduce pain and anxiety was effective for most patients. For example, VR was effective in reducing dental anxiety (SMD −1.74, 95% CI −2.46 to −1.02; *P*<.001; I^2=95%) and pain (SMD −1.57, 95% CI −2.22 to –0.91; *P*<.001; I^2=91%) among pediatric patients in a study by Yan et al [85]. Further, Eijlers et al [18] stated that when VR was applied as a distraction during venous access or during dental, burn, or oncological care in pediatric nursing, pain (SMD 1.30, 95% CI 0.68-1.91) and anxiety (SMD 1.32, 95% CI 0.21-2.44) were reduced. However, the effect of VR on fear was controversial [25,39]. In a meta-analysis by Saliba et al [67], VR seemed to be useful in reducing the fear of 648 children with burns (SMD 0.89, 95% CI 0.16-1.63; *P*=.02), but they found that there was significant heterogeneity among included studies. Czech et al [47] considered fear scores, and their study revealed no significant differences between the VR and no VR conditions. Heterogeneity was moderate or substantial in many studies (range 0.56-0.99), which may be the result of the different assessment scales used in each included study.

VR in Surgical and Wound Care

A total of 11 meta-analyses focused on surgical and wound care. The results of these meta-analysis studies showed that VR technology intervention for pain [43] (SMD 0.95, 95% CI 0.32-1.57) and anxiety [32] (SMD 0.36, 95% CI 0.20-0.52) was effective. Heterogeneity was low for anxiety (range 0.00-0.23) [2] but substantial for pain (range 0.44-0.80) [72]. Georgescu et al [43] summarized RCTs and found that the cognition of

1452 patients who underwent surgery or wound care statistically improved (SMD 0.94, 95% CI 0.33-1.56; I^2=51%), while the range of motion of patients with burns did not show better progress [2].

VR in Oncological Nursing

A total of 11 meta-analyses focused on cancer nursing, including symptom management and rehabilitation nursing, especially for breast cancer. The results of these meta-analysis studies showed that VR technology intervention was effective for pain (mean difference −1.27, 95% CI −2.05 to –0.50; *P*=.001), depression (SMD −2.89, 95% CI −5.46 to –0.32; *P*=.03), and anxiety (SMD −4.93, 95% CI −8.00 to –1.87; *P*=.002) among most patients with breast cancer [66]. However, when combined with its effects for other types of cancer, the effect of VR on pain, anxiety, and depression became controversial. Heterogeneity was substantial for anxiety and pain [73] but low for depression.

VR in Gerontological Nursing

A total of 10 meta-analyses focused on gerontological nursing. The results of these meta-analysis studies showed that VR technology intervention by nurses to improve balance (SMD 0.56, 95% CI 0.25-0.87; *P*<.001) was effective [29], while its effectiveness for motion capacity was controversial. Studies showed that virtual motor training had no significant positive effects [37,80]. Heterogeneity was moderate or substantial for exercise capacity, cognitive function, and balance [29,37,80].

Safety Concerns Regarding VR-Related Adverse Effects

Only a few papers reported adverse effects caused by using VR. The prevalence of adverse effects in these studies ranged from 4.76% to 50%, and these adverse effects included nausea, vomiting, sickness, dizziness, fatigue, pain, and the risk of losing balance.

VR Platforms and Intervention Times Among Different Populations

There were various platforms used for VR. We summarize the typical VR technology platforms used for different populations and outcome indicators in Table 3. The most commonly used VR platforms were Pico VR glasses, head-mounted displays, the Nintendo Wii, and the Xbox Kinect. The duration of VR intervention ranged from 2 weeks to 12 months (the most commonly reported durations were ≥4 weeks), and the length and frequency of VR sessions ranged from 5 to 100 minutes and from 1 to 10 times per week, respectively.

Table . Typical virtual reality (VR) platforms and intervention times among different patients.

Populations and outcome indicators		Platforms	Intervention duration	Session length and frequency
Neurology				
	Depression	Nintendo Wii, Xbox Kinect, and HMD[a]	6-12 wk	30-60 min, 2-5 times/wk
	Cognition	Pico UI 4.0, Nintendo Wii, Xbox 360 Kinect, BioMaster 2012, Lokomat, and Oculus	2-12 wk	20-100 min, 2-10 times/wk
	Daily living	Pico UI 4.0, Nintendo Wii, Xbox 360 Kinect, Armeo Spring, RehabMaster, BioMaster 2012, and Toyra VR	2-12 wk	12-60 min, 2-5 times/wk
	QOL[b]	Nintendo Wii, Xbox 360 Kinect, and Armeo Spring	3-8 wk	30-60 min, 2-5 times/wk
	Motion	Pico UI 4.0, Xbox 360 Kinect, Nintendo Wii, HMD, BioFlex, BioMaster, BioRescue, and ReJoyce	2-12 wk	20-90 min, 2-10 times/wk
Pediatrics				
	Motion	Pico UI 4.0, Nintendo Wii, and Xbox 360 Kinect	3-12 wk	30-100 min, 2-7 times/wk
	Distraction	Xbox 360 Kinect, HMD, ReJoyce, and Oculus	N/A[c]	5-35 min
Surgical and wound care				
	Distraction	Pico UI 4.0 and HMD	4 wk	30 min, 5 times/wk
Cancer				
	Anxiety, depression, and pain	Pico UI 4.0 and HMD	N/A	15-20 min
	Motion	HMD, Xbox 360 Kinect, and Nintendo Wii	4-8 wk	20-50 min, 2-5 times/wk
Older adults				
	Exercise capacity	HMD, Nintendo Wii, and Xbox 360 Kinect	2 wk to 12 mo	18-45 min, 1-5 times/wk
	Cognition	Xbox 360 Kinect, Nintendo Wii, and BioRescue	8-13 wk	18-30 min, 2-3 times/wk

[a]HMD: head-mounted display.

[b]QOL: quality of life.

[c]N/A: not applicable.

Discussion

Principal Findings

Clinical applications of VR in nursing practice predominately concentrate on neurology, pediatrics, oncology, surgical and wound care, and gerontology. Extant evidence indicates that VR interventions confer benefits for alleviating patient anxiety, pain, and depression, especially in pediatrics, among patients with breast cancer, and in wound care processes. VR is also a promising intervention for enhancing cognitive function in neurology patients. However, research on the utility of VR for improving motor function, balance, memory, and attention remains equivocal.

Many meta-analyses suggested that VR in nursing is useful for relieving anxiety and pain in patients, especially in pediatrics, among patients with breast cancer, and in wound care processes. Chen et al [62] found that a VR operation before surgery helped people familiarize themselves with the environment and understand the preoperative preparation procedures, thereby effectively reducing anxiety and improving compliance. Additionally, VR is a promising intervention for procedural pain [18,30], as reported in a study by Addab et al [92]. As a nondrug distraction intervention in nursing, VR can reduce the side effects of pain, depression, and anxiety drugs. However, heterogeneity was substantial in oncology studies and surgical and wound care studies. More high-quality studies are needed to help define the effectiveness of VR in these fields [93].

Further, VR can potentially be used to interfere with cognitive function, as it has been shown to affect cognitive plasticity and neuroplasticity. One study demonstrated plasticity in patients diagnosed with mild cognitive impairment and confirmed that repeated VR situational interactive training improved the excitability of the remaining nerve cells, promoted the functional reorganization of the damaged brain area, and resulted in the formation of new neural circuits, thereby improving the patients' cognition [94]. In a systematic review and meta-analysis that included 21 original studies (1149 participants), Chen et al [61] suggested that compared with a controlled group, VR training increased cognition because VR training increased the 1-naphthylacetic acid to creatine ratio in the hippocampus, which indicated that VR could improve the levels of hippocampal metabolites in patients with poststroke cognitive impairment, thereby promoting neuronal repair and improving cognitive function. However, several studies indicated that the effects of VR in nursing on cognition need to be clarified in more well-designed RCTs with large sample sizes because of small effect sizes, insufficient outcome indicators, and the low quality of current evidence [34,50,56].

The meta-analysis results showed that VR in nursing probably increased the exercise capacity of individuals undergoing neurologic rehabilitation when compared with usual nursing [60]. In contrast, many meta-analyses showed that there was little confidence that VR in nursing improves physical outcomes in older adults when compared with usual nursing [29,57]. The lack of allocation concealment and the absence of assessor blinding were the main causes of bias. As such, the final grade of the evidence was low, and the conclusions were hard to accept [37]. Some researchers thought that the results of VR therapy showed a trend of gait and upper limb function improvement in individuals [95,96], but Laver et al [31] believed that VR video gaming was not more beneficial than conventional nursing approaches in improving upper limb function, as did Voinescu et al [5]. Further, heterogeneity in protocols, VR task performance, and the different characteristics of the participants could have influenced the results [39]. Zhang et al [54] and Lei et al [13] pointed out that VR training helped to improve balance when compared with usual care. Similarly, Gates et al [97] and Saragih et al [98] concluded that VR training helped to improve balance when compared with usual nursing. All of these included studies did not analyze which subtypes of patients can benefit more from VR training in terms of improved balance, did not assess the long-term effects of VR on balance and mobility, and often included a relatively small number of patients and inadequate control groups [99]. The results need to be interpreted with caution due to the high heterogeneity, small sample sizes, and different outcome measures. In terms of improving memory, even after excluding studies with high heterogeneity, several meta-analyses still concluded that the effects of VR nursing measures on patients' instantaneous memory, long-term memory, and attention were not statistically significant [31,54,56]. The possible reasons for this are that VR training duration was too short to result in significant improvements [56] and only 6 studies (within the meta-analyses included in this umbrella review) with small samples were used to evaluate the effects of VR on attention.

It is also important to classify and summarize the VR platforms and frequencies of VR use that are commonly used in different nursing scenarios because of their influence on nursing outcomes. Meta-regression analyses showed that the number of VR sessions and the frequency of VR training had statistically significant impacts on balance scores [51]. There are few studies that explain why VR devices and scenes are chosen in a particular context, and there is no comparative analysis of the effects of using different VR devices and scenes in the same session. With regard to these biases, the included studies claimed that heterogeneity was due to the use of VR hardware with multiple types of VR software and variation in the duration of VR therapy sessions [93], which resulted in patients experiencing different levels of immersion, presence, and interactivity. Future research on VR in nursing should focus on providing a detailed report on VR device and platform instructions, the length and frequency of VR sessions, and the duration of VR intervention.

Comparison to Prior Work

Previous reviews on VR in nursing mostly discussed the impact of VR on nursing education and training at different levels [100,101]. However, the role of VR in clinical nursing practice is also very important. Therefore, we conducted this umbrella review, which aimed to effectively synthesize the combined evidence from meta-analyses that assessed the effects of nurses using VR technology on patients' health outcomes.

Strengths

This review followed the PRISMA reporting guidelines; thus, it can be viewed as a transparent and reproducible review. The findings in our review are more likely to be comprehensive and provide evidence for further VR application in clinical nursing practice. This study has a low risk of publication bias because we searched all relevant databases by using a reliable search strategy to identify as many eligible studies as possible. Moreover, we controlled the risk of selection bias by having 2 independent authors perform the research process, including the study selection, data extraction, and quality assessment processes.

Limitations

First, the quality of many included meta-analyses was not high. Therefore, the conclusions should be considered with care. Second, our study only reports on meta-analyses published in English, which may have resulted in language bias. Third, a quantitative data synthesis was not conducted in this review, given the significant clinical heterogeneity of the included studies in terms of study designs, intervention and population characteristics, and outcome measurements. This was one of the main reasons for the inconclusive research evidence found in this review. Follow-up studies can search for more literature, without strict language restrictions, and try to conduct high-quality quantitative syntheses to establish more reliable conclusions.

Future Directions

VR games have distinct clinical advantages, as they offer challenging and interesting environments [54]. Authoritative conclusions on the applications of VR in nursing might promote the application of VR games. It is suggested that nursing researchers should improve the quality of research; carry out large-scale, multicenter randomized controlled studies; and make authoritative conclusions on VR in nursing. In addition, the research outcomes of VR application in nursing are mostly subjective indicators, such as anxiety, depression, and satisfaction, and more objective outcome indicators, such as serological indicators, should be mentioned in the future. In the existing research, VR platforms, the duration of VR intervention, and the length and frequency of VR sessions are different. We hope that further research considers establishing standard operation protocols for VR intervention in specific populations.

Conclusions

Our study comprehensively summarized and indicated the potentially beneficial role of VR intervention in enhancing the management of pain, depression, anxiety, and cognition in neurology, pediatrics, oncology, surgical and wound care, and gerontology; the effects of VR intervention on improving motor function, balance, memory, and attention remain equivocal. However, these findings should be interpreted with caution due to the unsatisfactory quality of the included studies. It is recommended that more research of rigorous methodological quality is necessary to further determine the role of VR in promoting health care outcomes.

Acknowledgments

We thank the consultants of the Clinical Research Management Department in West China Hospital, Sichuan University, for their help throughout the study. This research was funded by the National Natural Science Foundation of China Regional Joint Project (grant U22A20334), the Chengdu Science and Technology Bureau (grant 2022-YF05-01440-SN), and the Chengdu Municipal Health Commission (grant 2022040).

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

YH, XY, and KL conceptualized this study. XY, YH, and PY were responsible for the methodology. YH, YHH, PY, CC, WZ, and XY were responsible for the software used. YH, PY, KL, CC, and XY were responsible for validation. YH, KL, and XY performed the formal analysis. YH, KL, WZ, and XY were responsible for the resources used. YH, PY, CC, WZ, and KL curated the data. YH, YHH, PY, CC, and XY wrote and prepared the original draft. YH, KL, and XY reviewed and edited this paper. KL supervised this study. YH and KL were responsible for project administration. YH and KL were responsible for funding acquisition. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Automated virtual reality (VR) therapy has the potential to substantially increase access to evidence-based psychological treatments. The results of a multicenter randomized controlled trial showed that gameChange VR cognitive therapy reduces the agoraphobic avoidance of people diagnosed with psychosis, especially for those with severe avoidance.

Objective: We set out to use a peer research approach to explore participants' experiences with gameChange VR therapy. This in-depth experiential exploration of user experience may inform the implementation in clinical services and future VR therapy development.

Methods: Peer-led semistructured remote interviews were conducted with 20 people with a diagnosis of psychosis who had received gameChange as part of the clinical trial (ISRCTN17308399). Data were analyzed using interpretative phenomenological analysis and template analyses. A multiperspectival approach was taken to explore subgroups. Credibility checks were conducted with the study Lived Experience Advisory Panel.

Results: Participants reported the substantial impact of anxious avoidance on their lives before the VR intervention, leaving some of them housebound and isolated. Those who were struggling the most with agoraphobic avoidance expressed the most appreciation for, and gains from, the gameChange therapy. The VR scenarios provided "a place to practise." Immersion within the VR scenarios triggered anxiety, yet participants were able to observe this and respond in different ways than usual. The "security of knowing the VR scenarios are not real" created a safe place to learn about fears. The "balance of safety and anxiety" could be calibrated to the individual. The new learning made in VR was "taken into the real world" through practice and distilling key messages with support from the delivery staff member.

Conclusions: Automated VR can provide a therapeutic simulation that allows people diagnosed with psychosis to learn and embed new ways of responding to the situations that challenge them. An important process in anxiety reduction is enabling the presentation of stimuli that induce the original anxious fears yet allow for learning of safety. In gameChange, the interaction of anxiety and safety could be calibrated to provide a safe place to learn about fears and build confidence. This navigation of therapeutic learning can be successfully managed by patients themselves in an automated therapy, with staff support, that provides users with personalized control. The clinical improvements for people with severe anxious avoidance, the positive experience of VR, and the maintenance of a sense of control are likely to facilitate implementation.

Introduction

Background

gameChange is an automated virtual reality (VR) cognitive therapy designed to reduce agoraphobic avoidance and distress in everyday situations. In a multicenter randomized controlled trial with 346 people with psychosis, we found that gameChange led to significant reductions in avoidance and distress [1]. Overall, there were small effect size improvements in agoraphobic avoidance, agoraphobic distress, and perceptions of recovery. However, patients with the most severe agoraphobia, for example, those struggling to leave the home, had large effect size improvements in agoraphobic distress and avoidance as well as significant improvements in persecutory ideation, quality of life, and perceived recovery, which were maintained at 6 months.

Agoraphobic avoidance is understood from a cognitive perspective in gameChange. The avoidance is a defense (or safety-seeking) behavior in response to fearful thoughts [2,3]. Fearful thoughts often develop because of past unpleasant or threatening experiences. However, the fears are maintained as the absence of harm in the present moment is attributed to the use of defenses rather than there being no current threat. Even when in the anxiety-provoking situations, the use of more subtle defenses (eg, rushing or avoiding eye contact) plays the same maintaining role for catastrophic cognitions [4]. In treatment, defenses must be dropped so that the threat beliefs can be evaluated fully. This is not to overlook the fact that many patients with psychosis have had difficult experiences and may currently be living in adverse circumstances and potentially facing ongoing threats. Although there may not be current overt actions against the person, there can be more implicit and subtle forms of threat, particularly linked to stigma. Therefore, clinicians working with patients should always be aware of the potential for actual threat and assess appropriately.

On the basis of cognitive psychology principles, gameChange VR therapy was developed through a user-centered design process involving >500 hours of input from people with lived experience [5,6]. In 6 sessions, people enter interactive computer-generated simulations of everyday scenarios such as a café, a bus, or a physician's waiting room. Guided by a virtual coach, patients are encouraged to experiment with dropping defense behaviors and to evaluate their fears. A member of the staff is present to assist with the equipment and help plan homework tasks to consolidate the learning from VR. Consistent with the cognitive model, we found in the trial that improvements in agoraphobic anxiety and avoidance were mediated by reductions in both a wide range of threat cognitions and the use of within-situation defense behaviors [1].

Objectives

In this study, we used a peer research approach to try to understand the participant experience of gameChange VR therapy in depth. Peer research is steered and conducted by people with relevant lived experiences. Peer methods have the potential to facilitate greater depth and more nuanced data collection and analysis by enhancing rapport [7] and leveling power [8]. Working collaboratively with researchers from different backgrounds, including lived experience, can enhance the validity and trustworthiness of qualitative analysis [9,10]. Interpretative phenomenological analysis (IPA) is a qualitative approach that focuses on participants' lived experiences and how they make sense of them [11,12]. IPA was chosen as it explicitly acknowledges the role of the researcher in the interpretation, which complements the peer research approach of valuing the insights that lived experience can bring [11]. Template analysis can be used to extend and develop IPAs for larger samples [13]. We conducted a peer-methods qualitative study incorporating IPA and template analysis to explore participants' experiences with gameChange.

Methods

Overview

This was a qualitative peer-methods study investigating the experiences with gameChange VR therapy for agoraphobic avoidance. A multiperspectival design was used [14], and a peer research approach was taken, including collaboration with the gameChange Lived Experience Advisory Panel (LEAP). The LEAP was a panel of 12 people with lived experience of psychosis. Full details of the study methodology are provided in the published study protocol [15]. Criteria to ensure credibility in qualitative research [16,17] were used to inform the design and ensure rigor in the conduct of the study.

Ethics Approval

The study received Health Research Authority approval and Health and Care Research Wales approval (IRAS 256895), as well as ethics approval from the National Health Service (NHS) South Central - Oxford B Research Ethics Committee (19/SC/0075) as part of the gameChange trial.

Research Team

People with lived experience of psychosis and anxious social avoidance were involved in all stages of the study. The research team included peer researchers who had had similar experiences to those being explored, a qualitative researcher with lived experience of mental health issues that did not directly overlap with those of the participants, clinical psychologists who designed and used VR therapy, and a qualitative researcher who pioneered the IPA approach. The LEAP, facilitated by the McPin Foundation, a charity that promotes the use of lived experience in research, contributed to the design, conduct, and analysis of the study. We aimed to use the peer knowledge within the study at all stages, including the design, data collection, analysis, and presentation of the findings.

Participants

We recruited participants who had received gameChange VR therapy as part of the trial (ISRCTN17308399). The participants were people accessing NHS mental health services with a diagnosis of psychosis and self-reported difficulties going into everyday social situations because of anxiety. The inclusion and exclusion criteria for the trial are listed in the trial protocol [18]. The additional inclusion criteria for this qualitative study were willingness and ability to provide informed consent to participate in the interview and willingness to have the interview audio recorded.

Sampling and Recruitment

Consistent with IPA principles, the recruitment procedure sought homogeneity—the locus of homogeneity in this study was receipt of gameChange therapy. The primary sampling method was to invite a consecutive cohort of people in the final phase of the trial between April 2021 and September 2021. To explore different experiences of treatment using a multiperspectival design, we sought a larger sample size (N=20), including participants with low, medium, and high uptake of therapy. When possible, this was supplemented with purposive sampling to ensure variation across demographic characteristics (including age, gender, and ethnicity) and trial centers. The recruitment strategy was revised because of the high uptake of therapy in the trial (just under 90% of participants received a dose of therapy, which was defined as a minimum of 3 sessions). Therefore, the subgroups for the multiperspectival design were derived retrospectively from the data and are presented in the *Results* section.

A total of 27 people were invited to participate, of whom 7 (26%) declined and 20 (74%) consented. Participants were from each of the 5 trial centers that recruited participants from NHS mental health trusts across England: Avon and Wiltshire Mental Health Partnership NHS Trust; Greater Manchester Mental Health NHS Foundation Trust; Cumbria, Northumberland, Tyne, and Wear NHS Foundation Trust; Nottinghamshire Healthcare NHS Foundation Trust; and Oxford Health NHS Foundation Trust. Recruitment was facilitated by the local trial coordinator. Written or audio informed consent, including consent to the use of pseudonymized quotes, was obtained from all participants.

Procedure

The semistructured interview guide (Multimedia Appendix 1) was developed in collaboration with the LEAP, with reference to existing literature, and in line with the principles of IPA [19-21]. The guide was refined following pilot interviews with members of the LEAP. The guide was used flexibly, with a focus on eliciting the participants' own account. This involved using open-ended descriptive and narrative questions to explore the context, followed by individually tailored prompts to elicit further information or clarification and using the participants' own language whenever possible. The focus of the interview guide was on participants' experience with the gameChange therapy. It included questions such as *What is your experience of going out of the house or going into social situations?What was it like to be in everyday situations in virtual reality?* and *Compared to what you told us about your life before gameChange, is life different in any way now? How so?*

Interviews were conducted between April 2021 and September 2021. The first 40% (8/20) of interviews were conducted jointly by JB and AK, a further 55% (11/20) were facilitated by AK alone, and 5% (1/20) were facilitated by JB alone. Interviews were conducted remotely, either by phone (14/20, 70%) or web-based video call (6/20, 30%). The mean duration was 80 (SD 22; range 40-105) minutes, with most (13/20, 65%) completed over 2 sessions. The peer researcher chose when, how, and what to disclose about their related mental health experiences, and this differed between interviews. Both interviewers kept field notes, including on the use and impact of sharing the peer identity. Interviews were audio recorded, transcribed verbatim, and deidentified.

Analysis

A total of 25% (5/20) of the transcripts were coded using IPA [11,20]. IPA focuses on participants' lived experiences and how they make sense of them [11]. The remaining transcripts were analyzed using the initial IPA themes as a preliminary *template*. This work was conducted using template analysis [22], which can be used with IPA to analyze larger samples [13].

The multiperspectival design provides a structure for exploring both the individual account and related groups [14]. In our study, the subsamples were identified via preliminary analysis rather than via sampling strategies. Four subsamples related to overall experience and the impact of therapy were identified: (1) *Big changes* (4/20, 20%), (2) *Better ways to cope* (9/20, 45%), (3) *Hard to say or hard to hang on to* (5/20, 25%), and (4) *Struggling on* (2/20, 10%).

The 25% (5/20) of transcripts included in the IPA analysis were selected based on the richness of the data and to ensure a range of trial sites and ages and a balance of gender. To maintain the homogeneity of the sample, a requirement of IPA, the 5 transcripts expressed a similar perspective on gameChange. The analytical procedure for IPA followed the approach outlined by Smith et al [11,20]. This included line-by-line annotation of each transcript, mapping what mattered to each participant ("objects of concern") with the meaning assigned to the experience ("experiential statements"). Meanings were clustered and interpreted for each case. Across cases, themes were identified that encompassed the phenomenological experiences and understanding of the 25% (5/20) of participants, forming superordinate and subordinate themes. IPA provided the foundation for the subsequent template analysis.

A provisional *template* was developed from the IPA themes and used to initiate the template analysis of the remaining data. The template analysis followed the steps outlined by King et al [22]. In line with the multiperspectival design [14], the transcripts were introduced in subgroups, focusing on each in turn. Analyzing the data in these batches made comparisons between perspectives starker. New codes were assigned and the template was updated at least once after each group was added. Once all data had been analyzed, the template was reviewed against all transcripts. Two analysis sessions were held with the LEAP to develop the template. LEAP members were given an overview of the themes and shown a selection of quotes. The focus was on identifying patterns within the data, resolving ambiguity in the accounts, and considering how the participants' experiences resonated with their own.

The IPA analysis was conducted by JB, AK, and LC. DR and VP contributed to the template analysis. Supervisory support was provided at each stage of the analysis by ML and FW.

Reflexivity and Credibility

All members of the research team reflected on the different perspectives that they brought to the study design, setup, data collection, and analysis. For example, in the analysis, the peer researchers drew on their lived experience to support their interpretation of meaning in the data; this was particularly relevant when exploring meanings related to participants' experiences of anxious avoidance and psychosis.

Credibility checks were conducted with members of the gameChange LEAP. Their input was used to corroborate and deepen the interpretation of the themes. The reflexive logs, transcripts, interview schedule development, and minutes of supervisory research team meetings provided an audit trail for analysis. Illustrative quotes, description of the study context, and participant characteristics allowed for an assessment of the transferability of the findings to other settings and contexts.

Results

Contextualizing the Data

A total of 20 people participated: 11 (55%) women and 9 (45%) men. The average age of the participants was 37 (SD 12.9) years. In total, 85% (17/20) of the participants identified as White British individuals, 10% (2/20) identified as British Asian individuals, and 5% (1/20) identified as Polish. As can be seen in Table 1, most (15/20, 75%) participants were unemployed. A total of 20% (4/20) of the participants said that they spent a lot of time playing computer games and described themselves as "gamers." In total, 60% (12/20) of the participants attended 6 sessions of therapy, and 40% (8/20) attended 7 sessions. For 55% (11/20) of the participants, these VR sessions were facilitated by a clinical psychologist; for 30% (6/20) of the participants, it was an assistant psychologist; and 15% (3/20) of the participants worked with peer support workers. The participant characteristics in this qualitative study were consistent with those in the main trial (see the trial outcome report [1]).

Table 1. Participant characteristics (N=20).

Demographic and clinical characteristics	Participants, n (%)
Marital status	
Single	15 (75)
Married	3 (15)
Divorced	1 (5)
Cohabiting	1 (5)
Employment	
Unemployed	15 (75)
Retired	2 (10)
Carer	1 (5)
Employed (full-time)	1 (5)
Student (part-time)	1 (5)
Living situation	
Living with parents or another relative	8 (40)
Living alone	7 (35)
Living with others	4 (20)
Living with a spouse or partner	1 (5)
Mental health service context at the time of interview	
CMHT[a]	15 (75)
EIP[b] team	5 (25)

[a]CMHT: community mental health team.

[b]EIP: early intervention in psychosis.

Overview of Findings

An overview of the key findings is presented. This is followed by a description of the subgroups identified for the multiperspectival design. The cross-case analysis of participants' experiences with the intervention is then presented. Illustrative quotes, with details omitted to protect anonymity, are presented in the text and in Multimedia Appendix 2.

Summary of Key Findings

There were 5 superordinate themes (Textbox 1). First, anxious avoidance carries a cost. Participants described living restricted lives in which fears made it hard to do everyday activities. Second, participants shared their curiosity and motivation to try VR therapy. Third, VR therapy provided a place to learn about anxiety and practice different or new responses. Fourth, the VR simulations triggered an anxiety response, yet participants simultaneously recognized that the environments were largely safe. This interaction of anxiety and safety could be calibrated by the individual to provide a safe place to learn about fears and build confidence. Finally, VR was a training ground to do things differently. Through practice and conversations with the member of the staff who was present, participants took the key learning from VR into the real-world situations that mattered to them.

Textbox 1. Overview of superordinate and subordinate themes.

- Experience and cost of anxious avoidance
- Reasons to try: curiosity and motivation
- A place to practice
  - An immersive experience
  - A chance to observe anxiety
  - New ways of responding
- The security of knowing it is not real
  - The sweet spot of safety and anxiety
  - Calibrating for a personalized approach
- Taking it into the real world
  - From training wheels to real-world practice
  - One thing to hold onto

The 4 Perspectives

Overview of the 4 Perspectives

We identified 4 subgroups of participants based on the descriptions of their experience and impact of the gameChange therapy. The descriptions varied from life-changing to experiencing little change, although all described gameChange as a valuable experience. Illustrative quotes for each subgroup are presented in Table 2.

Table 2. Illustrative quotes from the participant subgroups (N=20).

Subgroup	Participants, n (%)	Illustrative quotes
Big changes	4 (20)	• "It's very different now, I can open my curtains and look out my window, I can go out to local shops and places, I can meet up with friends and family, I can do such a lot more." [Participant 27] • "Before I would never do that, ever. But I did that and I was talking to new people and I was having a great time. It's just being in social situations instead of hiding from them, I'm just trying to embrace them." [Participant 8]
Better ways to cope	9 (45)	• "It definitely helped with anxiety. I still suffer from some of the things I did, well, all of the things I did before, but it's definitely, definitely helped it in some way." [Participant 3] • "Before I'm just looking at the floor wherever I'm going but now I'm looking at everyone, like, in their eyes and stuff. Even though I'm still too scared to go to the supermarket on my own, I have been able to walk past it on my own, like walk up there and past it, whereas before I wouldn't have been able to do that. I've been in small shops on my own and the bus, I can do that on my own now without worrying." [Participant 25]
Hard to say or hard to hang onto	5 (25)	• "Now because my mood is quite good, I'm thinking, 'Yeah, actually. I did take away stuff.' But when I'm really anxious, like I have been really anxious over the last couple of weeks...and then I'm like, I haven't learnt anything." [Participant 17] • "I mean I wasn't too bad with a lot of the situations anyway, so I don't know if I've taken a lot from it, but I'd like to think I have but I'm not entirely sure. I'm not entirely sure if it's had any massively notable impact on me." [Participant 13]
Struggling on	2 (10)	• "It has not really made a magical difference for me, unfortunately, but I can see how it can be very helpful. I think I'm just too entrenched in my avoidance little bubble, that it wasn't strong enough to pull me out of it. It's just the same." [Participant 19] • "Like, I say, still go to cafes, still get on the bus, go shopping. I didn't go food shopping yesterday. I was really, really anxious yesterday in town with the boys. I couldn't do my food shopping. My body wouldn't let me do it. My mind affects my body." [Participant 26]

Big Changes

A total of 20% (4/20) of the participants described gameChange as a transformative experience. Participants in this group marveled at how far they had come—they were able to do things they had not imagined at the start of therapy, when they were often housebound and experiencing very low mood. These accounts were characterized by excitement and enthusiasm.

Better Ways to Cope

A total of 45% (9/20) of the participants described experimenting with new ways to approach and cope with situations despite some ongoing anxiety. For these participants, social situations were less stressful but not yet comfortable.

Hard to Say or Hard to Hang Onto

A total of 25% (5/20) of the participants noted some small changes following therapy but found these hard to identify when asked directly or hard to maintain when anxiety increased or mood dipped. Participants valued aspects of the therapy but did not necessarily find that the VR scenarios triggered their anxiety. Participants in this group were often able to engage in some social situations before starting therapy.

Struggling On

In total, 10% (2/20) of the participants recognized the potential of the therapy but described little personal benefit as they struggled with psychotic experiences. They continued to feel anxious in the familiar and often essential (eg, shopping) situations they were able to engage in even before the start of therapy.

Main Themes

The Experience and Cost of Anxious Avoidance

All participants spoke about the cost of anxious avoidance. Some participants described themselves as almost housebound, others avoided specific situations, and a few could perform essential tasks in an area where they felt safe. However, all felt the burden and restriction of anxious avoidance:

> *It affects my life big time because I can't do half the things that I want to do or what a normal everyday person would do. I want to do something but sometimes it can hold me back and it can really affect the way you think, the way you act and the person that you are.* [Participant 27, Big changes subgroup]

As in the previous extract, participants shared the reasons for withdrawal: many felt threatened by others, at risk of physical or social harm, or that others were observing or talking about them. Some were anxious about showing symptoms in public as they feared that this would draw attention and invite judgment. Participants described the tactics that they had developed to try to reduce these risks, but some strategies had life-limiting effects. Some described their situation as intolerable, affecting self-esteem and quality of life, disrupting careers, impeding friendships, and making them feel "almost not like a human being." Although all participants described life being "limited" by anxious avoidance, not all were distressed by inhabiting a small world.

Reasons to Try: Curiosity and Motivation

As VR therapy was new to the participants, most had no preconceived notions of what gameChange would be like or how it would help. Many said that they were “open-minded” to try gameChange. However, the reasons to engage differed:

> *I went in with an open mind. I was willing to give anything a go because I just didn’t want to be in the same state I was in after episode one.* [Participant 3, Better ways to cope subgroup]

> *I’m interested in technology, new technology. It’s quite exciting. So, that really encouraged me to get involved as well.* [Participant 1, Big changes subgroup]

As mentioned previously, for some, the opportunity appeared when they were ready to receive and engage with it. Others noted that experiencing a difficult time before gameChange fueled their desire for change. This was often accompanied by a sense of personal responsibility for the intervention’s success. Some were open to gameChange as they had been unwell for a long time and were keen to try anything that could alleviate their symptoms. Others simply saw it as an opportunity to do something in an otherwise restricted life: “I don’t really have anything to do so I was like: ‘Go on then, I might as well do it’” (participant 7, *Hard to say* subgroup).

The use of VR in gameChange was appealing to more than half (11/20, 55%) of the participants. Those who had heard of VR were attracted by its novelty, they were “interested” or “intrigued” to see what it would be like. They understood its therapeutic use as “a modern new way to treat social anxiety”:

> *I was, like, curious, I suppose, yeah. Its cutting-edge technology, isn’t it?* [Participant 26, Struggling on subgroup]

Of the 4 participants who identified as gamers, 3 (75%) were primarily attracted to the intervention as it was a chance to use VR.

A Place to Practice

> *I really enjoyed it. Well, I say enjoyed it, it was actually quite hard work. I found it very realistic when I went in, more than I expected, I think. And it was a lot harder than I thought it was going to be.* [Participant 1, Big changes subgroup]

Most (14/20, 70%) participants, including one of the 4 gamer participants, were surprised by how realistic it was. Participants seemed to be struck by its immersive quality:

> *Going into VR was like going into another world, kind of thing. It was really like everything was not realistic, you could tell it was all fake, but at the same time you felt like you were actually in there.* [Participant 25, Better ways to cope subgroup]

> *It was like being in a film, it was. You put the helmet [VR headset] on and you’re taken to another world.* [Participant 26, Struggling on subgroup]

Immersion was created by the graphics, background noise, and interactive details:

> *You can open the door. You can lift a can of beans up and put your bank card on the meter to pay for it. I thought it was amazing.* [Participant 21, Better ways to cope subgroup]

This immersion and perceived realism meant that many participants saw the VR scenarios as a meaningful environment to practice in. Participants who identified as gamers tended to be less impressed with the VR world.

Participants described developing new insights into their experience of anxiety, as described in the following extract:

> *I didn’t realise things like I was looking for an escape route and going to it. And now, I’m aware of that, I cannot do it so much. You know, it’s just sort of being aware.* [Participant 1, Big changes subgroup]

Being in the VR simulations could trigger anxiety. Participants spoke of sweaty palms and racing hearts and of realizing that they were unconsciously trying to use coping mechanisms such as looking for an escape route or exit, avoiding eye contact, or diminishing their physical presence. For some, this was a hard and shocking realization:

> *...that was really an eye-opener, and I was quite shocked at how it has affected my life for so long.* [Participant 27, Big changes subgroup]

VR provided an opportunity to observe anxiety and automatic responses with some emotional distance. It was “a buffer” or a chance “to step back and think about how they are reacting,” as members of the LEAP described it. Responses that were overwhelming and panicked in real life could be slowed, picked apart, and rerun. A LEAP member commented that VR was like a magnifying glass, clarifying the details and nuances of the situation. This led to participants developing greater understanding of what happens in moments of anxiety. This could be empowering and raised the potential to change these automatic responses.

Participants described VR as a place to practice new ways of responding in situations:

> *Make eye contact. I smile a bit more at people. Little things you don’t realise you haven’t been doing till you go and do the headset. It made me realise a lot, that I had just focused my life around the voices and not taken any notice of the outside world. That’s why I’ve been taking more notice of things when I’m out now.* [Participant 23, Better ways to cope subgroup]

The automated virtual coach and staff member made suggestions to drop defenses and try new strategies to build confidence. Despite the anxiety, it was safe to try new approaches as participants knew that the VR was not real.

“The Security of Knowing It Is Not Real”

The nature of VR means that, despite knowing that it is a simulation, reactions are typically real—as evidenced in the anxiety responses that the participants experienced:

> *Even though you’d tell yourself that you’re in a safe environment and the people weren’t going to necessarily react as you would expect a real-life person to react, your brain is still telling you that you’re in danger and you’re at risk here so yes, it did*

> *make you feel quite anxious.* [Participant 2, Big changes subgroup]

However, knowing that the VR simulations were not real allowed participants to feel a sense of safety:

> *It makes you face your fears but in a less extreme way because these people, you know aren't real, but you still have the feeling of it being people.* [Participant 16, Better ways to cope subgroup]

Participants described an active interaction between safety and anxiety. For example, a sense of safety was required for participants to "slowly push themselves out of their comfort zone" (participant 8, *Big changes* subgroup), try the new ways of responding that the automated virtual coach and staff member suggested, and learn to tolerate discomfort. This was a delicate balance. If anxiety was "dialled" too low, VR was perceived as boring and ineffective. If safety was "dialled" too low (or anxiety too high), VR was intense and draining:

> *It's a fine line: you want it to be realistic enough, so it's a good practice, but it's also quite helpful if it's not totally realistic because then you get that security of knowing that it's not real.* [Participant 1, Big changes subgroup]

As mentioned previously, participants understood the importance of locating this "sweet spot," noting that it was sometimes helpful that the VR was not photorealistic or that they knew they were in no danger despite feeling bodily symptoms of anxiety. Finding the right balance could be difficult. For some participants, aspects of the VR scenarios matched real-world triggers, leading to fears or memories of past difficulties and resulting in spikes in anxiety. At these moments, it was sometimes hard to feel safe enough to create new learning in VR.

Levels of anxiety and safety could be calibrated by and to the individual through choice of the levels within the program or by the actions of the staff member:

> *The deliverer knew if I was putting defences up and she would tell me different ways to cope. There was one scenario where I was in the street and people walked past and I put my defences up because I kept looking at them walking past and my therapist said to relax and look at the cars and describe what's in the cars and stuff.* [Participant 11, Hard to say or hard to hang onto subgroup]

The features of the software that often increased anxiety were "realness" and immersion in the scenarios, background noise, the scenarios becoming more crowded, and specific tasks such as waiting in a queue. Features that increased the sense of safety were that the characters and scenarios did not look as real as the real-world situations, the gradual increase in intensity of the levels, and having the option of removing the headset.

There were layers of support from the virtual coach, Nic, and the staff member. Those with higher baseline levels of anxiety described the coach as comforting, and participants appreciated her guidance and encouragement:

> *When I did a level, she would be like, "Well done, you did great." She was good in that sense. It was someone familiar that I would see every time I went in.* [Participant 25, Better ways to cope subgroup]

Those who were more confident in VR described the coach as "repetitive," "slow," and at times "irritating."

The staff member was able to build on the generic support that was programmed in the software through the virtual coach, increasing the participants' sense of safety to facilitate more exploration and experimentation in VR. The staff member was attuned to the participants' responses, suggesting pauses, encouraging repetition of scenarios or levels that they found challenging, or helping identify and drop specific defenses:

> *I think the deliverer was quite helpful in saying: "In that one you appeared more anxious, do you want to do that one again? You spoke a bit quietly in that one, did you want to do it again, you didn't seem that confident doing that one, would you like to try it again?"* [Participant 15, Better ways to cope subgroup]

> *I would use coping strategies. I didn't realise until the deliverer would tell me what I did—I didn't recognise it myself—so, the deliverer would tell me certain things that would give me more confidence for the VR, but also, when leaving the session as well.* [Participant 3, Better ways to cope subgroup]

In this way, the sweet spot of anxiety and safety could usually be found for each person, creating the conditions for them to try new ways of responding in the VR scenario.

Taking It Into the Real World

> *The fear was there but what I was fearing didn't actually happen which was good. That, for me, was part of the therapy in the sense that it made you realise that what you fear is going to happen isn't necessarily what will happen. It made you re-evaluate if you like your way of thinking.* [Participant 2, Big changes subgroup]

Participants understood that VR was a safe place to do things that scared them—"training wheels" where they could take "baby steps"—before translating them to the real world:

> *The everyday situations that I found difficult, the more I practised them in the VR, the more I could get confident and be more confident in day-to-day life. I think because I was learning about it in the VR and practising and practising and practising, I could then take that and build up more confidence and do it in the everyday real world.* [Participant 27, Big changes subgroup]

> *I guess it's like the training wheels, isn't it? You get used to a situation simulating it and then go and try it in the real world.* [Participant 5, Hard to say or hard to hang onto subgroup]

Many participants recognized the need to practice between VR sessions and appreciated being given "homework." Some acknowledged that this structure helped them push themselves.

Others found additional ways to reinforce learning, such as writing notes and asking questions, periods of active reflection, and debriefing with the deliverer and other people. Some used sessions with their care teams to implement homework tasks. These participants were not deterred by circumstances such as COVID-19 restrictions hindering what they could do in the real world, and they were able to adjust the tasks around them. These participants tended to describe gaining the most benefit from the therapy and were in the *Big changes* and *Better ways to cope* subgroups.

Participants needed motivation to face anxiety-provoking situations—the potential rewards needed to be high enough for the effortful process of overcoming anxiety. This was observed in the descriptions of the 15% (3/20) of participants who already felt safe in their local environment and were unsure about the value of going further afield. These participants were in the *Struggling on* and *Hard to say* subgroups. For some, the relationship with the staff member was an important motivator to put into practice the learning from VR.

Through practicing in VR, participants described creating new learning and finding new explanations and understandings about themselves, other people, and the world. A common realization was that reality was not as bad as participants feared. The seed for these new beliefs was often found in VR—opportunities to make this discovery were embedded in the VR scenarios, for example, when characters smiled during interactions or simply did not respond as feared (eg, laughing or criticizing the participant). This new learning was tailored and reinforced by the staff member, ensuring that the key messages were personalized, succinct, and easy to recall. This learning often became most powerful when participants grew confident enough to push themselves in real life, making eye contact or small talk with people. These layers of corroboration, including discovery in VR, discussion with the deliverer, and real-world practice, made for a powerful learning experience. As well as embedding new beliefs, participants held onto memories created during gameChange. Some spoke of recalling scenes in VR or of positive experiences they had had afterward in the real world. This had a calming effect when they found themselves in a challenging situation:

> *It's like [the staff member] says, "stand confident and people will see you as confident. No one is looking at you. People do look, it doesn't say they're going to hurt you." It really helped me, because when I went out I thought of the gameChange.* [Participant 21, Better ways to cope subgroup]

The result of this practice and learning was that some participants saw changes that were important to them. The world had opened up for people whose lives were most restricted by agoraphobic avoidance:

> *I've been out on a couple of nights out and yeah, I've loved it really. Instead of hiding from it, I'm actually embracing it, I'm enjoying spending time with my friends because like I said I didn't see them for a long time in the first lockdown because of my mental health and the state of mind I was in, it's great seeing them now.* [Participant 8, Big changes subgroup]

> *It's a case of not thinking twice about getting the bus and getting take away coffee now. I'm quite happy to do it which was a big change for me.* [Participant 2, Big changes subgroup]

Discussion

Principal Findings

Facilitated by peer methods, participants provided rich and informative accounts of the problem of agoraphobic anxiety and avoidance, the experience with automated VR therapy, and its impact on their lives. The restriction caused by severe agoraphobic avoidance has a substantial cost in people's lives. Variations in the benefits of VR therapy were observed across the participant groups. Participants who were close to housebound (4/20, 20%) tended to report "big changes" from the gameChange VR therapy, whereas individuals who were reasonably comfortable with the boundaries of the locations that they could visit (5/20, 25%) tended not to report so much impact from the VR sessions. This perspective from the qualitative interviews of variation in benefits of VR therapy was gained before the trial outcome results were known by those involved in the qualitative analysis but were entirely consistent with the main trial findings. The largest group identified (9/20, 45%) derived benefit from gameChange—they developed "better ways to cope"—but in a less transformational way than the group who saw "big changes." Their accounts suggest that, before the intervention, they were more able to perform everyday activities than the other group, but they were still distressed by their agoraphobia. These results support the conclusion that the implementation of gameChange is best focused first on people with the most severe agoraphobic difficulties.

There was further consistency with the quantitative findings. Participants reported a wide range of fears contributing to agoraphobic avoidance, as has been found using self-report assessments [4]. Furthermore, the participants viewed VR as a popular treatment option with limited mention of any side effects, which is consistent with our surveys across the whole group that received gameChange [23]. However, the interviews provided greater depth on several important issues. They provided an intriguing perspective on the therapeutic nature of immersive technology. Participants reported how VR—as they knew they were experiencing simulations—provided the chance to gain distance on anxious responses and try new alternative ways of thinking and behaving. Therapeutic gains arose out of a delicate balance of experiencing typical anxious responses but only to a degree in which safety could also be kept in mind. In this way, safety feelings could begin to feel like a realistic appraisal of the situations. This calibration was largely determined by the users, for example, selecting the scenario or level within the program, but there could also be invaluable support from the staff member who was present. A degree of guided support, even with automated therapies, is likely to be very important. It was also clear that participants considered that, to make change, it was important to apply the learning to real-world situations via the homework tasks. Conversations with the supporting staff member were valued. A common realization among those who gained benefits was that reality was not as bad as they feared. There are opportunities to further tailor the treatment to the individual by increasing the range of scenarios available and adapting the demographics of the virtual coach.

Conclusions

The interviews provided fascinating in-depth insights into the experience with automated VR therapy, which will inform the delivery of gameChange alongside other implementation and health economic studies [23-25]. This study has several limitations. The participants interviewed were not representative of all those who received VR therapy. For instance, we only succeeded in interviewing participants who completed therapy, which is largely a reflection of the high uptake of VR therapy in the trial. This means that we would have missed important specific challenges and barriers for individuals who did not complete VR therapy. The participant group was also not representative of the wider population of people attending mental health services. There was a lack of ethnic diversity in the participants interviewed. Understanding the potential barriers faced by underserved and underrepresented groups will be important for future implementation. We also note that the interviews and therapy were conducted during the COVID-19 pandemic. The context of restrictions, disruption, and anxiety may have affected the experience of agoraphobic avoidance and VR therapy. Finally, the lengthy interviews that covered multiple questions mean that it is likely that we may only have been able to capture a fraction of participants' experiences in this report.

Acknowledgments

The authors thank the study participants and other people who worked on this study. They are grateful to the gameChange Lived Experience Advisory Panel for their valuable contribution to the study design, materials, and analysis. Members include Debbie Butler, Susie Booth, Len Demetriou, Zach Howarth, and Mary Mancini. gameChange was funded by the National Health Service National Institute for Health and Care Research (NIHR) Invention for Innovation program (Project II-C7-0117-20001). This work was also supported by the NIHR Oxford Health Biomedical Research Centre (BRC-1215-2000). DF is an NIHR Senior Investigator. The views expressed are those of the authors and not necessarily those of the National Health Service, NIHR, or Department of Health. FW is supported by a Wellcome Trust Clinical Doctoral Fellowship (102176/B/13/Z).

Authors' Contributions

All the authors contributed to the study design. TK facilitated the LEAP. Data were collected by JB and AK. JB, AK, and LC conducted the primary analysis with contributions from DR and VP. FW and ML provided supervision. JB, FW, DF, and DR wrote the first draft of the manuscript. All the authors approved the final version of the manuscript.

Conflicts of Interest

DF is a founder and nonexecutive board director of Oxford VR, a University of Oxford spin-out company, which programmed and commercializes the gameChange treatment. DF holds equity in Oxford VR and receives personal payments. DF holds a contract for his university team to advise Oxford VR on treatment development. The University of Oxford, Oxford Health National Health Service Foundation Trust, and the McPin Foundation received a share of the licensing fee from Oxford VR for the gameChange software. SL does some consultancy work for Oxford VR. The other authors have no conflicts to declare.

Abstract

Background: Gamification in smoking cessation apps has been found to improve cognitive outcomes associated with higher odds of quitting. Although some research has shown that gamification can also positively impact behavioral outcomes such as smoking cessation, studies have largely focused on physical activity and mental health. Only a few studies have explored the effects of gamification on smoking cessation outcomes, of which the majority have adopted qualitative methodologies and/or assessed engagement with apps using self-report.

Objective: This study aimed to explore levels of user engagement with gamification features in a smoking cessation app via in-app metrics. Specifically, the objective of this paper was to investigate whether higher engagement with gamification features is associated with the likelihood of quitting in the short term.

Methods: Data from a larger online study that recruited smokers seeking to quit were analyzed to address the objectives presented in this paper. The study took place between June 2019 and July 2020, and participants were primarily recruited via social media posts. Participants who met the eligibility criteria used 1 of 2 mobile apps for smoking cessation. In-app metrics shared by the developer of one of the smoking cessation apps, called Kwit, were used to assess engagement with gamification features. Out of 58 participants who used the Kwit app, 14 were excluded due to missing data or low engagement with the app (ie, not opening the app once a week). For the remaining 44 participants, mean (SD) values were calculated for engagement with the app using in-app metrics. A logistic regression model was used to investigate the association between engagement with gamification and 7-day smoking abstinence.

Results: In total, data from 44 participants who used the Kwit app were analyzed. The majority of participants were male, married, and employed. Almost 30% (n=13) of participants self-reported successful 7-day abstinence at the end of the study. On average, the Kwit app was opened almost 31 (SD 39) times during the 4-week study period, with the diary feature used the most often (mean 22.8, SD 49.3). Moreover, it was found that each additional level unlocked was associated with approximately 22% higher odds of achieving 7-day abstinence after controlling for other factors such as age and gender (odds ratio 1.22, 95% CI 1.01-1.47).

Conclusions: This study highlights the likely positive effects of certain gamification elements such as levels and achievements on short-term smoking abstinence. Although more robust research with a larger sample size is needed, this research highlights the important role that gamification features integrated into mobile apps can play in facilitating and supporting health behavior change.

Introduction

Despite steps taken to tackle the global tobacco epidemic, smoking-related health disability and mortality remain concerning [1]. While the majority of smokers want to quit smoking, research shows that in many countries such as the United Kingdom, long-term abstinence rates remain low [2]. In addition to low smoking cessation rates, face-to-face access to cessation services has been falling in several countries [3]. Digital health solutions, such as mobile apps, have been found to be effective methods of reaching individuals unwilling or unable to access in-person services. However, low engagement and retention are common challenges for mobile apps. The integration of gamification, the use of game elements in a nongame context [4], has been found to be positively associated with higher app engagement [5,6]. Some examples of gamification elements, also known as on-screen features or tactics, include goal setting, levels and badges, progress tracking, and progress sharing. Since gamification shares key elements with behavior change theories, it is often applied to health behavior change interventions [6].

Prior research shows that engagement with gamification elements in smoking cessation apps can positively impact cognitive constructs vital for abstinence such as self-efficacy and motivation to quit [7]. Although research also shows the positive effects of gamification on behavioral outcomes, the majority of existing studies have focused on physical activity and mental health [8]. A few studies that explored the association between engagement with gamification and smoking cessation adopted qualitative methodologies and assessed engagement using self-reported data rather than objective app usage metrics [6,7]. We aimed to explore the level of user engagement with gamification elements in a smoking cessation app via the analysis of in-app metrics. We also aimed to investigate whether engagement with gamification elements is associated with the likelihood of achieving short-term smoking abstinence.

Methods

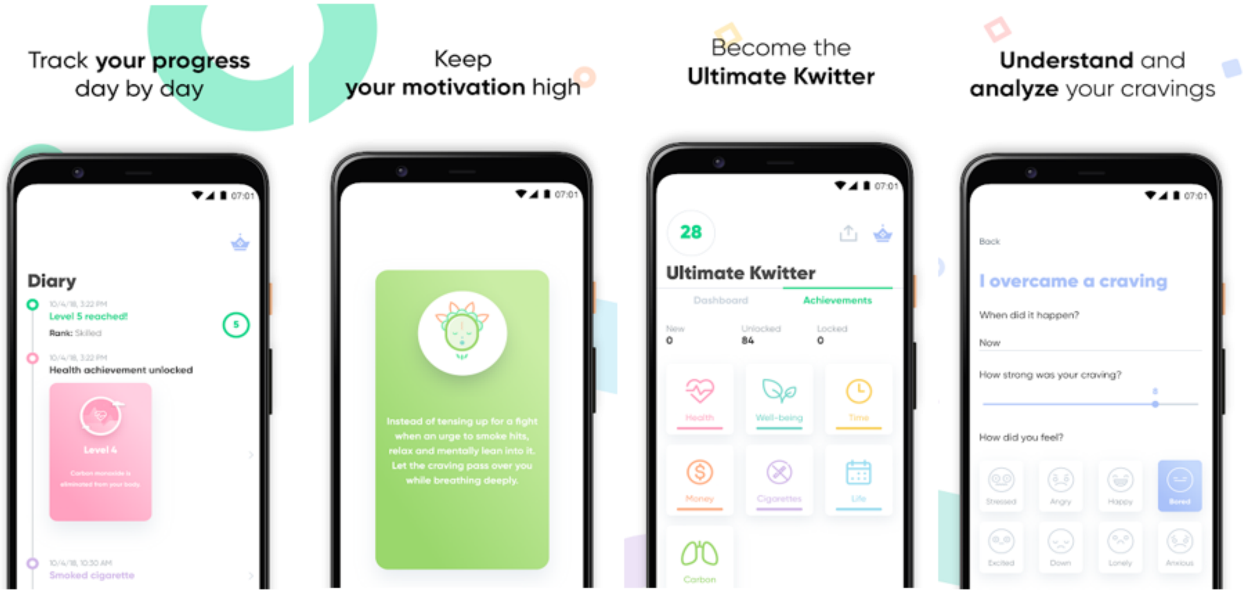
Study Overview

The data used for this paper's analyses were collected as part of a larger online study that took place from June 2019 to July 2020 and explored the effects of gamification on cognitive constructs vital for smoking cessation [7]. Participants were recruited via posters in public places in London, United Kingdom, and posts on various social media channels such as Facebook and Instagram. Interested participants were asked to fill out a screening questionnaire to assess eligibility. Eligible participants (Table S1, Multimedia Appendix 1) were assigned 1 of 2 smoking cessation apps; this paper focuses on users of Kwit, a gamified mobile app designed to help smokers quit smoking using cognitive behavior therapy [9]. Participants had to use the app at least once a week for 4 weeks and complete a questionnaire before (baseline), 2 weeks after (mid-study), and 4 weeks after app use (end of study). In-app metrics shared by the app developer were used to assess engagement with features. Out of the 70 participants who were assigned Kwit, 58 (83%) completed the study. A participant was considered to have completed the study if they self-reported to have engaged with the app at least once a week for the duration of the study and completed all questionnaires. Aside from free app access, participants had a chance to win a £50 (US $60) Amazon voucher.

The Kwit App

Kwit is a mobile app, developed by Kwit SAS, that aims to help smokers quit and successfully remain abstinent from smoking. It uses cognitive behavior therapy principles and gamification to assist individuals [9]. The app consists of features such as a smoking diary to log cravings and triggers, motivation cards, and a calculator/tracker to monitor self-progress in relation to key achievements. Figure 1 presents screenshots of the app, showing the smoking diary feature, an example of a motivation card, the achievements tracking page, and how users can track cravings. App versions 4.1 to 4.4 (June 2019 to July 2020) were used by participants.

Figure 1. Screenshots of the Kwit app.



Measures

Sociodemographic measures included age (18-29 years, 30-41 years, 42-53 years, and 54-65 years), gender (male or female), marital status (single, married, or civil partnered), and employment status (unemployed: individuals willing or able to work but not employed; employed; nonemployed: students, individuals unable to work, and homemakers). Similar to other studies, the Fagerström questionnaire was used to assess nicotine dependence with responses categorized as low (0-4 points), moderate (5-7 points), and high (8-10 points) [10,11]. Additionally, to measure abstinence, participants were asked at the end of the study, "Have you smoked at all in the past seven days?" to assess the 7-day point prevalence of smoking abstinence. Participants who responded "No, not even a puff" were considered short-term quitters. Participants who selected other responses ("Yes, just a few puffs"; "Yes, between 1 and 5 cigarettes"; and "Yes, more than 5 cigarettes") were categorized as smokers.

Aside from self-reported data, objective in-app metrics were also used in the analysis. Kwit SAS routinely collects and maintains a database of app usage statistics, including various user interactions with specific features and the app overall. Kwit SAS provided in-app metrics for the participant identification numbers shared with them. The metrics included the number of times the app was opened, levels completed, smoking diaries logged, achievements unlocked, and motivation cards viewed. Additional information on the in-app metrics is presented in Table S2 (Multimedia Appendix 1).

Statistical Analysis

The statistical software Stata 16 (StataCorp) was used for the analysis. Descriptive statistics were used to present general participant characteristics, nicotine dependence, and 7-day abstinence. Mean (SD) values were calculated for the in-app metrics. Unadjusted logistic regression models were run for each in-app metric to explore its association with 7-day abstinence. The specifications of the adjusted logistic regression model were based on an iterative process that considered collinearity. Significance was set at the 5% level (*P*<.05), and 95% CIs were presented.

Ethics Approval

The study was conducted in accordance with the recommendations for physicians involved in research on human subjects adopted by the 18th World Medical Assembly Declaration of Helsinki 1964 and later versions.

Ethical approval was obtained from the Joint Research Imperial College London Research Ethics Committee prior to the beginning of the study (reference: 19IC5158).

Results

Among the 58 participants who completed the study (self-reported app usage once a week over the study duration and completion of all questionnaires), 14 participants were excluded from the analysis due to issues with the in-app metrics (eg, missing or inconsistent data; n=9) or due to inadequate engagement according to the in-app data (ie, the app was not used once a week; n=5). Table 1 shows that more than half of Kwit app users were 18 to 29 years of age (n=24, 55%). A majority were male (n=27, 61%), married (n=35, 80%), and employed (n=28, 64%). Moreover, the majority of participants had low to moderate dependence on nicotine (n=42, 95%). Almost a third (n=13, 30%) reported at the end of the study that they successfully abstained from smoking in the past 7 days.

As seen in Table 2, Kwit users opened the app almost 31 (SD 39) times on average over the 4-week study period. Among the metrics that were collected, the most frequently used features were logging of smoking diaries (mean 22.8, SD 49.3) and unlocking of achievements (mean 22.3, SD 16.5). Additionally, over the study period, motivation cards were opened on average 8.0 (SD 11.2) times and 7.7 (SD 4.9) levels were unlocked by Kwit users.

In the adjusted logistic regression model (Table 3), each additional level unlocked was associated with approximately 22% higher odds of achieving 7-day abstinence after controlling for other factors such as age and gender (odds ratio 1.22, 95% CI 1.01-1.47). The number of diaries logged and motivation cards opened were not significantly associated with 7-day abstinence in the adjusted model. The number of achievements was not included in the model since it was highly correlated with the number of levels. However, when the logistic regression model was rerun with the number of achievements instead of levels, the results suggested that each interaction with the achievements feature was associated with a 7% increased likelihood of reporting 7-day abstinence (95% CI 1.01-1.15).

Table 1. Characteristics of the study sample.

Characteristics	Participants (N=44), n (%)
Age	
18-29 years	24 (55)
30-41 years	13 (30)
42-53 years	4 (9)
54-65 years	3 (7)

Discussion

Principal Findings

We found that after 4 weeks of app use, almost 30% of smokers reported 7-day abstinence. This rate is generally within the range reported by other mobile app studies [12]. However, direct comparisons are difficult due to differences between interventions and varying methods of measuring cessation. Mobile app interventions such as Kwit can be associated with an increased likelihood of abstinence compared to no assistance or using willpower alone [13]. This study opens the possibility of using smoking cessation apps to aid individuals who are not accessing face-to-face services [14].

The analysis also found that engaging with levels was significantly associated with 7-day abstinence. According to Gnauk et al [15], levels are important as they can function as a goal-setting tool that marks progression and signals accomplishment. Similarly, the achievements or badges feature was also found to be associated with an increased likelihood of reporting abstinence. Achievements and levels are similar as they both provide regular feedback to users and remind them of their successes. This can lead to an increase in perceived competence, which facilitates health behavior change [16]. Generally, the positive effect of providing regular feedback in both remote and face-to-face interventions is well established [17]. Aside from the importance of features such as levels and achievements, it was also found that the likelihood of reporting abstinence was not statistically different with regards to age and gender after adjusting for engagement with app features. This could imply that any effects that Kwit may have on smokers might not vary by age or gender. However, it is important to note that the small sample size could impact the generalizability of the findings.

Limitations

The observational nature of the study does not allow for causal inference; future research could carry out a rigorously designed randomized controlled trial with apps that differ only with regards to the type and number of gamification features. Aside from the sample size, the attrition of participants from 70 to 44 participants could pose a threat to the internal validity of the study and limit the generalizability of the findings. Additionally, since research has shown that relapses in abstinence can occur over a longer period of time, the relationship between engagement with gamification features and long-term quitting cannot be determined; future research could consider having a longer follow-up period [18,19]. Furthermore, validating smoking abstinence using biochemical verification is the gold standard and would be recommended to increase the robustness of future research studies.

Although the use of in-app metrics in mobile app studies is sparse and provides an objective method of assessing engagement with app features, it may not have captured the full engagement experience of users. For example, we were able to assess the number of times users engaged with specific gamification elements but not the length of engagement. While this is an imperfect measure of engagement, it can be considered a more objective method (compared to self-report) that is not frequently adopted in mobile app studies.

Conclusions

The overall learnings from this research highlight that features such as levels and achievements can positively impact short-term smoking abstinence. While further investigation is warranted with a larger, diverse sample and a longer follow-up period, our findings have positive implications for the use of gamification in mobile apps to support behavioral outcomes such as smoking cessation.

Acknowledgments

This research did not receive a grant or funding from any agencies that are public, commercial, or within the not-for-profit sector. Kwit provided free access to the study participants but had no other financial input.

Authors' Contributions

NBR, NM, and FTF were involved in the study design. NBR collected the necessary data and drafted the manuscript. DW and LB contributed to the data analysis and manuscript write-up. All authors read and approved the final manuscript.

Conflicts of Interest

LB undertakes consultancy and research for the Kwit app (Kwit SAS) in a PhD contract involving the National Association of Research and Technology and the University of Paris Nanterre. The other authors have no conflicts to interest to declare.

Abstract

Background: Complete blood count (CBC) and hemostatic screening tests are among the most commonly prescribed blood tests worldwide. All health care workers (nurse practitioners, pharmacists, dentists, midwives, and physicians) are expected to correctly interpret the results in their daily practice. Currently, the undergraduate hematology curriculum consists predominantly of lecture-based teaching. Because hematology combines basic science (blood cells and hemostasis physiology) and clinical skills, students report that they do not easily master hematology with only lecture-based teaching. Having interviewed students at the University of Lorraine, we considered it necessary to develop new teaching approaches and methods.

Objective: We aimed to develop and validate a serious game about CBC analysis for health care students. Our primary objective was to help students perceive hematology as being a playful and easy topic and for them to feel truly involved in taking care of their patients by analyzing blood tests. We considered that this game-based approach would be attractive to students as an addition to the classic lecture-based approach and improve their knowledge and skills in hematology.

Methods: We developed an adventure game called SUPER HEMO, a video game in which the player assumes the role of a protagonist in an interactive story driven by exploration and problem-solving tests. Following validation with beta testing by a panel of volunteer students, we used a novel, integrated teaching approach. We added 1.5 hours of gaming to the standard curriculum for a small group of volunteer students. Physician and pharmacy students in their third year at a single French university were invited to attend this extracurricular course. Pregame and postgame tests and satisfaction surveys were immediately recorded. Final hematology exam results were analyzed.

Results: A total of 86 of 324 physician students (26.5%) and 67 of 115 pharmacy students (58%) opted to participate. Median scores on the pre- and posttests were 6 out of 10 versus 7 out of 10, respectively, for the physician students, (P<.001) and 7.5 out of 10 versus 8 out of 10, respectively, for the pharmacy students (P<.001). At the final hematology evaluation, physician students who played SUPER HEMO had a slightly better median score than those who did not: 13 out of 20 versus 12 out of 20, respectively (P=.002). Pharmacy students who played SUPER HEMO had a median score of 21.75 out of 30; this was not significantly different from pharmacy students who did not play SUPER HEMO (20/30; P=.12). Among the participants who answered the survey (n=143), more than 86% (123/143) believed they had strengthened their knowledge and nearly 80% (114/143) of them had fun.

Conclusions: Feedback from this game session provided evidence to support the integration of interactive teaching methods in undergraduate hematology teaching. The development of SUPER HEMO is intended to be completed so that it can become a support tool for continuing education.

Introduction

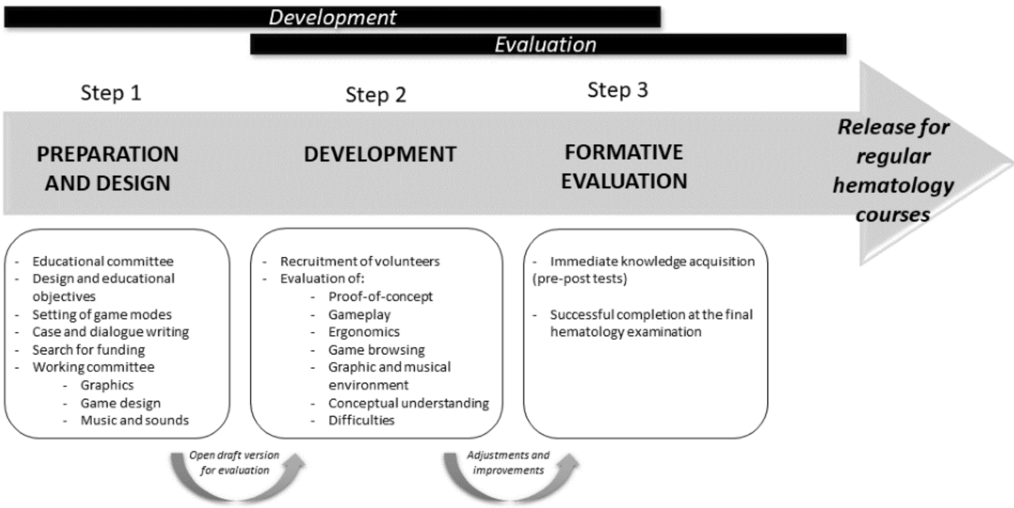
Numerous serious games (SGs) have been developed to improve nursing [1] and medical [2] knowledge and skills. The main subjects are surgery [3-5], emergency medicine [6,7], pharmacy [8] for health care students, and other subjects, such as preventive medicine for adolescents and young people [9-12]. Systematic reviews of SGs conclude that they seem to be at least as effective as other digital education modalities [13], but pedagogical effectiveness, participant behavior, and patient health outcomes have barely been evaluated [14-16].

In the context of the global COVID-19 pandemic, the demand for online learning increased worldwide. However, it has been reported that reduced peer and teacher interaction can cause motivation issues [17,18]. Recently, online learning has been described negatively, especially by health care students in clinical practice [19]. Many health care students see working in the health care setting as a vocation rather than a job, with patient-centered and compassionate care being the basis of this view [20]. Therefore, video games that enable specifically situated, experiential learning by introducing different unwell characters represent an attractive learning tool for today's students, who are very receptive to computer-based learning.

SGs for hematology education are rare and deal only with transfusion [21,22]. One important part of hematology education is complete blood count (CBC). CBC is a quantitative and qualitative evaluation of blood cells and stands as one of the most common laboratory tests in medicine, being indicated for a vast number of conditions. CBC interpretation is taught only with lecture-based courses in hematology. An internal survey among physician and pharmacy students at the University of Lorraine revealed that more than 50% of students considered CBC interpretation hard to master. Because correctly applying CBC knowledge to form patient diagnoses and make clinical decisions is a requirement for all health professionals, we decided to implement an SG for hematology education.

We developed an SG (Figure 1) named SUPER HEMO with a structured, 3-phase development framework that included preparation and design, development, and formative evaluation, as described previously [23].

Figure 1. SUPER HEMO development.



Methods

Preparation and Design

Framework

As a reference for the creation and development of the game, we took inspiration from role-playing and adventure games (eg, point-and-click games and visual novels), as these are commonly played at home by students. The game's contents, including a database with questions, answers, and feedback, were based on knowledge from the Collège national des enseignants en hématologie (the French national college of hematology teachers).

At first, we created an educational committee composed of 3 hematology experts (1 pharmacist and 2 medical doctors), a pharmacist with gamification expertise (with no expertise in hematology), and an instructional designer. Meetings took place every month for the first 6 months of the project. The goals of this committee were to define pedagogical objectives, game design, and game modes, and to write the clinical cases' dialogue. During the writing of the clinical cases, physician students volunteered to test some of the cases before their integration into the game. The committee also looked for funding. The raised funds were mainly used to hire a graphics designer and a game developer.

Then, a working committee was created with 2 medical doctors, a pharmacist with hematology expertise, a pharmacist with gamification expertise, an instructional designer, a graphics designer, and a game developer. Meetings occurred every 2 months to discuss practical issues arising from game conception.

Some members worked together outside of the meetings in groups, such as the graphics designer with the hematology expert or the game developer with the instructional designer and the hematology expert.

The project was then presented to the pedagogical council of each faculty.

Story

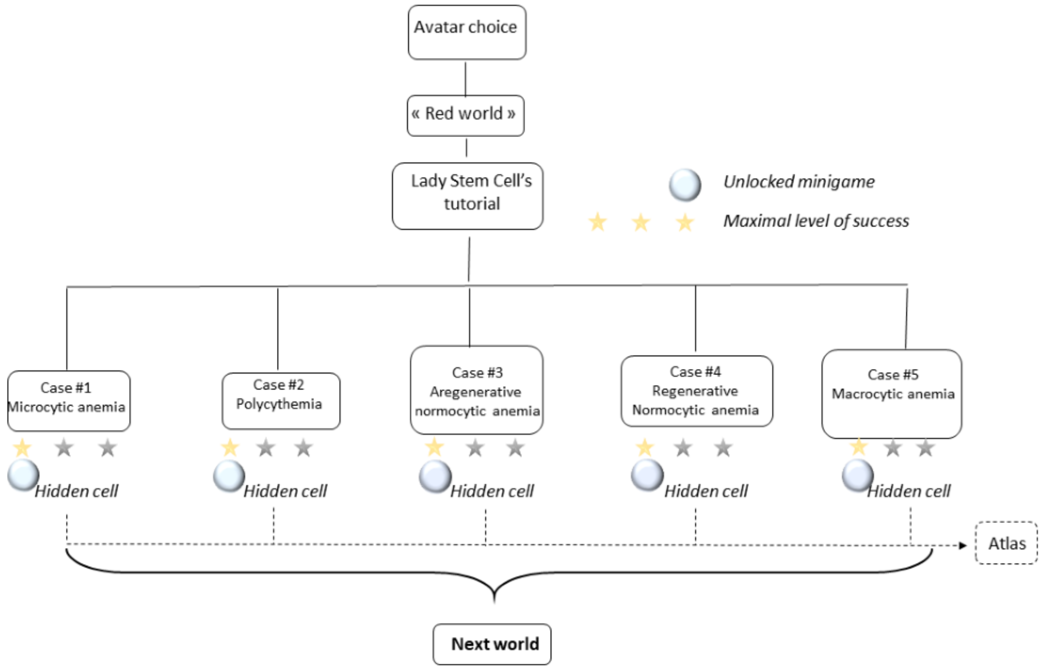
SUPER HEMO is set in a dreamlike "Red Cell World" (Multimedia Appendix 1), with red-blood-cell trees and depictions of the organs involved in erythropoiesis, including a "lung mountain," "medullar cave," "kidney rock," "spleen fortress," and "thyroid isthmus."

Players can choose a female or a male avatar on the home screen. They then complete the introduction, in which "Lady Stem Cell" explains the world and the game's settings and instructions and gives the player the "CBC asset," which is the power to check the blood parameters of the unwell characters encountered and interpret the corresponding results. Players assume the role of a hematology superhero named SUPER HEMO. SUPER HEMO can meet 5 unwell characters in 5 different steps. The player must answer their questions and find the best way to diagnose and cure them. "Magicians" (radiologists, pathologists, hematology-biologists, pharmacists, and geneticists) can be summoned to help the player find the right answer (Multimedia Appendix 2) in exchange for gold coins.

Mechanics

To complete the world's challenges (Figure 2), SUPER HEMO must explore 5 clinical cases.

Figure 2. "Red World" mechanics.



Each stop (represented by a light blue button) corresponds to the clinical case of an unwell character. Players choose to explore the clinical cases in the order that they decide. When SUPER HEMO successfully ends a case, players are rewarded with 1, 2, or 3 stars depending on the number of errors they made. Moreover, a hidden hematopoietic cell can be caught to unlock a minigame to earn gold coins. A wrong answer to a skill question makes SUPER HEMO lose the patient's trust and lose gold coins, and a wrong answer to a treatment question makes the hero lose the patient's trust. Lady Stem Cell gives immediate feedback to every question, thus maintaining the user's motivation and commitment to the game [24]. If all gold coins and the patient's trust are lost, Mister Insurance takes SUPER HEMO back to the beginning of the case, where the player can immediately play again if they have enough gold coins; otherwise, they can still earn gold coins in minigames before trying the case again. The hidden collected cells constitute an atlas of hematopoietic cells that contains a precise description and a real picture (taken by microscopy) of each blood cell. Minigames are always related to hematology in a fun way.

When SUPER HEMO reaches 80% success in the world's 5 clinical cases (and achieves a total of 12 stars of a possible 15) the player wins a new asset (a myelogram) and is thereby allowed to move on to a higher level, which corresponds to another hematopoietic world.

Throughout the game, to maintain the dreamlike atmosphere and immersion, different theme songs accompany the player (with the possibility to mute them). The player also has the option to reset the game on the home screen (not pictured).

Development

Technology

The game was programmed in January 2019 using C# in the Unity game engine, for computers only (ie, there was no mobile app). The invention was protected with an Inter Deposit Digital Number on September 9, 2020, for the University of Lorraine.

To date, the game is available in French only and is free of charge at the University.

Video Game Beta Tests

Three beta-test sessions were organized with small groups of undergraduate and graduate physician and pharmacy volunteer students. The goal was to obtain a primary evaluation of the game design and concept and to debug the game. The volunteers played the game for 1 hour and were then asked to fill in a questionnaire (Multimedia Appendix 3) about several aspects of the game, including the graphical interface, gameplay, use of multimedia, and educational content, and provide ideas for improvement and general comments. We collected the questionnaires and analyzed the answers to modify or improve the game and the teaching methods, if required.

Formative Evaluation

Ethics Approval

The study was conducted in accordance with the Helsinki Declaration and Resolution. The study was approved by the Pedagogic Committee of the Faculté de Pharmacie, Université de Lorraine (June 17, 2021) and Faculté de Médecine, Université de Lorraine (July 7, 2021).

Recruitment and Game Evaluation

Students in their third year of medicine and pharmacy courses were identified as the most appropriate study participants, since hematology is a regular and mandatory course unit during this academic year. These student cohorts were expected to benefit the most from additional exposure to clinical learning while using SUPER HEMO, as their upcoming final exams were planned to take place shortly after game exposure. The game evaluation was performed after 2 weeks of classical hematology teaching. The gaming course consisted of 1.5 hours of gaming (in the Red World) that covered the following standard red blood cell disorders: anemia and polycythemia. The game evaluation was split into 2 phases examining (1) the immediate knowledge acquisition of the players and (2) whether the players successfully completed their final hematology examination.

First, to evaluate the effectiveness of this teaching method, voluntary participants from each course were asked to complete a knowledge test consisting of 10 multiple-choice questions (Multimedia Appendix 4); one point was obtained for each correct answer. The participants completed the 10-question test before (pretest) and after playing the game for 1 hour (posttest). An online questionnaire was designed to assess playability and the students' understanding of SUPER HEMO. Students were also asked to rate their level of confidence after the gaming session on a questionnaire. Qualitative data considering the students' general feedback was also collected. All answers were anonymized.

Second, successful completion of the final hematology examination was extracted for students who had participated in SUPER HEMO and those who had not by the pedagogic committee, and mean results were compared.

Statistics

Statistical analyses were carried out using Prism (version 5.0; GraphPad). Comparisons of participation rates for the physician and pharmacy students, as well as the female to male ratio of the groups, were made with the Fisher exact test. Pre- and posttest scores and the final evaluation were expressed as median values, with the range and 25th to 75th percentiles. Pre- and posttest results were compared using a paired Wilcoxon signed-rank test in the 3 groups (ie, the overall population, the physician students, and the pharmacy students). Final evaluation results were compared using the Mann-Whitney test. As participation was on a voluntary basis, a post hoc power analysis of the final evaluation's scores was also performed.

Results

Beta Tests

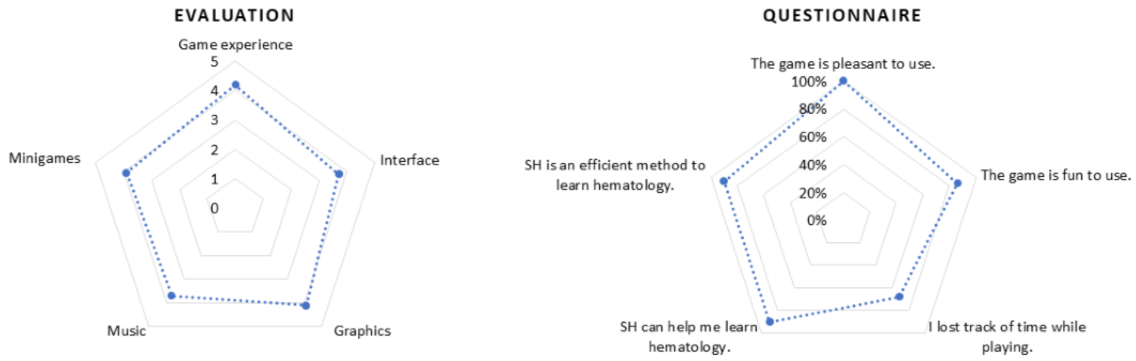
The results of the 3 beta tests (Figure 3) indicated a significant interest in this new SG.

The interface received a score of 3.7 of 5. As for the multimedia aspect, the graphics and music received scores of 4.1 and 3.7 of 5, respectively. All students stated that they enjoyed the game, 86% (19/22) found the game fun to use, and 68% (15/22) even lost track of time while playing. Regarding the educational content, 90% of the students (20/22) found that SUPER HEMO represented an efficient method to learn hematology.

The beta tests allowed us to detect a few points to improve SUPER HEMO and address issues encountered by the students. Some students had difficulties answering certain types of questions (for example, ones that used drag-and-drop), or they could not find the minigames. This led us to integrate tutorials at the beginning of each game, such as on how to answer questions encountered for the first time. We also modified some questions and minigame rules to better drive the players. Moreover, some players forgot the CBC results while talking to the unwell characters and frequently wanted to check them; therefore, we added a button to allow the players to check the CBC results as often as they wanted to. Finally, as the game tasks could be interrupted, we added a "log info" button to remind the students of dialogue text.

The free comments included mostly thanks for the initiative and anticipation for the sequels.

Figure 3. Beta-test results. SH: SUPER HEMO.



Integrated Teaching Approach in Addition to the Standard Hematology Undergraduate Curriculum

A total of 153 volunteer students were recruited, including 86 of 324 physician students (26.5%) and 67 of 115 pharmacy students (58%), who agreed to participate in this complementary session at the end of the standard lecture-based hematology course. Of note, the proportion of female students was higher in the participant group (Table 1).

Overall, the volunteer students were evaluated on a 10-point scale (Table 2 and Figure 4). They had a higher posttest score (median 7.5, range 2.5-10) than pretest score (median 6.5, range 1.5-9; *P*=.001), indicating that the game slightly improved their immediate knowledge acquisition. The median pre-and posttest scores were 6 (range 1.5-8) and 7 (range 2.5-10), respectively, for the physician students (*P*<.001) and 7.5 (range 3-9) and 8 (range 3.5-10), respectively, for the pharmacy students (*P*<.001).

At the final examination (Figure 4), we observed that the physician students who played SUPER HEMO obtained a slightly higher score (median 13/20, range 6-17) than those who did not play SUPER HEMO (median 12/20, range 5-17; *P*=.002), with a satisfactory study power (83%). The pharmacy students who played SUPER HEMO had a score (median 21.75/30, range 12.25-27.25) that was not statistically significantly different from those who did not play SUPER HEMO (median 19.8/30, range 9.5-26.75; *P*=.12). Unfortunately, the study power was low (64%) for this group.

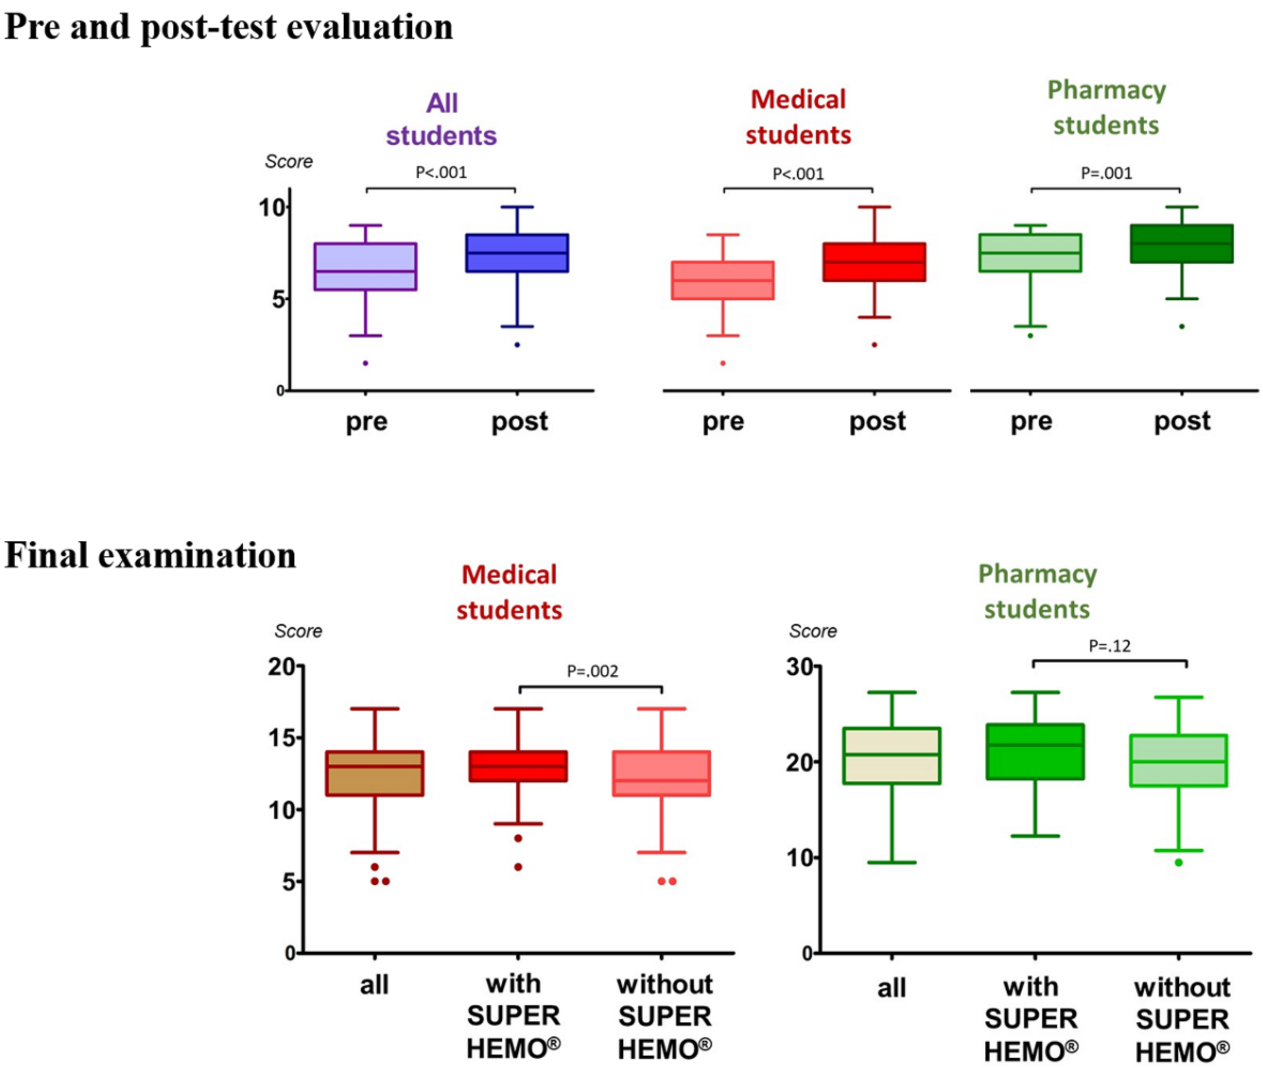
Table 1. Comparison of participants and nonparticipants in SUPER HEMO evaluation.

Characteristics	Participants, n	Nonparticipants, n	*P* value
All students (N=439)			<.001
Female	110	161	
Male	43	125	
Physician students (n=324)			.05
Female	60	136	
Male	26	102	
Pharmacy students (n=115)			.02
Female	50	25	
Male	17	23	

Table 2. Pre- and posttest evaluations (scores are on a 10-point scale).

	Pretest			Posttest			*P* value
	Median score	Range	25th-75th percentile	Median score	Range	25th-75th percentile	
All students	6.5	1.5-9	5.5-8	7.5	2.5-10	6.5-8.5	<.001
Physician students	6	1.5-8	5-7	7	2.5-10	6-8	<.001
Pharmacy students	7.5	3-9	6.5-8.5	8	3.5-10	7-9	.001

Figure 4. SUPER HEMO evaluation.

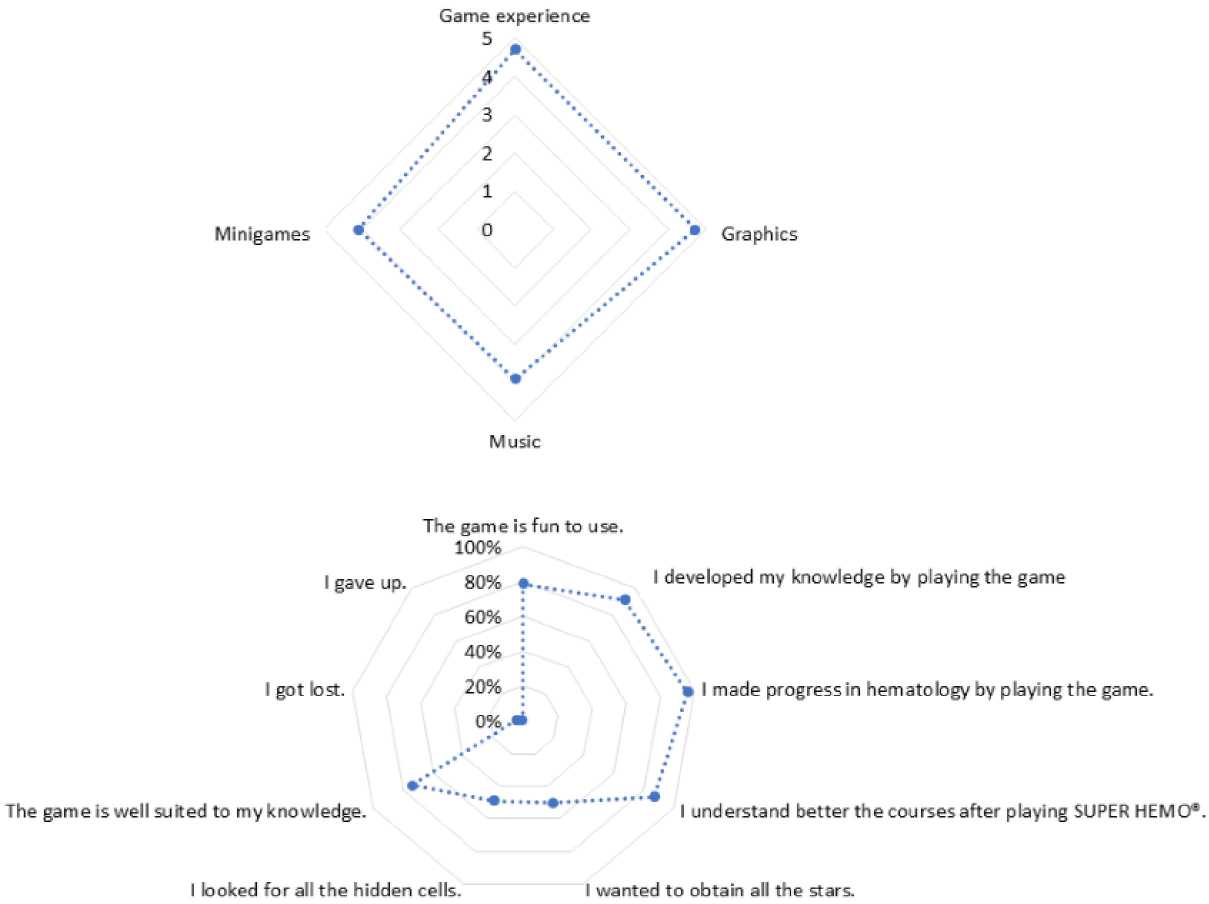


Gameplay Satisfaction

Among 153 volunteer students, 143 answered the questionnaire (93.4%). Game experience received a score of 4.7 out of 5, and 79% of the students (n=113) found the game fun to use. Regarding multimedia, graphics received a score of 4.7 out of 5, and music received 3.9 out of 5. The minigames were scored as attractive (4.1/5; Figure 5).

Concerning the educational content, most of the 153 students indicated that they had augmented their knowledge (n=130, 91%), had made progress in hematology (n=137, 96%), and better understood their courses (n=124, 87%) after playing SUPER HEMO. In addition, 71 students (50%) indicated that they specifically aimed to obtain the top 3 stars at the end of each case in the game, and 70 students (49%) dedicated specific effort to collect all the hidden cells. While the effect of rewards on memory appears well documented, it has recently been reported that incentives can also have counterproductive effects on memory [25]. Our videogame reward system was, however, developed to create a realistic game environment with well-known reinforcement and reward schedules. Of the 153 participants, 106 (74%) indicated that the flow of the game suited their knowledge, zero indicated they were bored by the game, 5 (3%) became lost in the game, and only 1 gave up.

Figure 5. Gameplay satisfaction.



Discussion

Principal Findings

SUPER HEMO was developed to increase students' motivation for learning hematology. In fact, as previously described, when students feel involved, they are more likely to achieve educational goals [26]. But with only 4 hematology teachers at the university, bedside (for clinical symptoms) and laboratory (for cell recognition) teaching in undergraduate medical education could not be fully accomplished for that year's 324 physician and 115 pharmacy students. Consequently, SUPER HEMO was developed to confront students with different clinical situations, improve their cell observation skills, and supplement the classical teaching model. Because players may have different skills, we developed the pedagogic content concomitantly with gamification [27]. Special characters, such as Lady Stem Cell, were created to regularly debrief the players on wrong or right answers to questions [28]. SUPER HEMO level 1 (the Red World) was developed and beta tested over a 2-year period. Subsequently, SUPER HEMO's approach was integrated to the standard hematology undergraduate curriculum of third-year physician and pharmacy students and the SG was evaluated.

In health care education, studies comparing SGs to other teaching methods with prospective evaluations are scarce [29,30]. We assumed that this prospective evaluation might be useful to justify SUPER HEMO's integration with the standard hematology curriculum. The satisfaction questionnaire clearly showed that most students enjoyed playing SUPER HEMO (113/142, 80%) and felt that they learned from it (123/142, 86%). These results demonstrate the students' strong commitment to the game. This result was reinforced by the free comments (eg, "I find the interface truly attractive; it really makes me want to do well" and "A good experience, dialogs or context are quite funny but still remain consistent!"). Several students inquired about playing the rest of the game (eg, "We're looking forward to the white and yellow worlds' release" and "I hope I can play again soon!"). Students highlighted the link between the game and seriousness (eg, "It allowed me to study in a fun way" and "Fun way to learn hematology or to practice without the feeling that I have studied").

Knowledge improvement with this complementary method to the standard course was more difficult to evaluate. If a positive effect of SUPER HEMO was clearly observed for short-term knowledge (ie, the results of the pre- and posttests), the measurement of learning outcome (ie, the results of the final examination) should also be discussed. First, the first SUPER HEMO session ran through the COVID-19 pandemic, when restrictions were in place on attending courses. Therefore, we could not evaluate the effectiveness of this SG with a randomized controlled trial. After discussion with the pedagogic committee during the pandemic, courses were transmitted virtually to students who wanted to stay at home; less than 10% of students attended on site. In order not to penalize medically or psychologically fragile students, we decided to invite students to participate as they chose to do so. We can hypothesize that volunteer students who came to the SUPER HEMO session were the most motivated in the class, thus biasing the results of the final exams. Second, we observed that pharmacy students were more likely to attend the SUPER HEMO session than the physician students. Of note, the pharmacy students were probably more motivated, as their final exam took place a few days after the gaming session, whereas the physician students had their final exam 1 month after the gaming session. For the pharmacy students, although the participation rate was satisfactory, the study was underpowered, suggesting that follow-up studies (within the next few years) with more students might confirm that playing SUPER HEMO allowed students to obtain a better score in the final hematology evaluation (as was observed for the physician students). Third, our conclusions on interest in SUPER HEMO should be moderated by consideration of the SUPER HEMO session design. The session had a time limit of 90 minutes and was based only on the available "Red World," which dealt with anemia and polycythemia, while the final evaluation contained questions on red blood cells, white blood cells, and platelets. We therefore propose that in the future (1) three worlds corresponding to the three lineages of hematopoietic cells in the CBC be made available to encompass the whole hematology program, (2) game-based learning should have no time restrictions, and (3) new evaluations with more participants should be organized with other universities.

Currently, we consider that our research contributes to the literature by providing a new game for teaching hematology and an investigation of the effectiveness of the SG context for hematology learning. This first experiment with SUPER HEMO commits us to develop this SG for hematology in future academic years. Future work will focus on developing levels 2, 3, and 4, the "White World," "Yellow World," and "Complex World," respectively, with all parameters varying in the latter. We propose an evolving game that covers the entire program of hematology and is accessible on the digital platform of the University of Lorraine. SGs have been poorly developed for hematology education. Tan et al [21] were the first to report an SG, developed for nurses in Singapore, that dealt with the safe administration of blood transfusions. This SG was prospectively tested with 103 second-year undergraduate nursing students randomized into control or experimental groups. Posttest knowledge and mean scores for confidence improved significantly in the experimental group ($P<.001$) after the SG intervention compared to mean pretest scores and mean posttest scores for the control group ($P<.001$). However, no significant differences ($P=.11$) were found between the experimental and control groups for mean posttest performance scores. Four years later, the participants evaluated the SG positively as an innovative and stimulating learning tool; however, more rigorous efforts to improve the interface and alleviate technical issues were suggested as ways to make the SG more accessible and intuitive for all levels of nursing staff [22]. To our knowledge, SUPER HEMO is the first SG developed for CBC interpretation to be used by teachers of hematology for students in medicine, pharmacy, dentistry, and midwifery. During the COVID-19 pandemic, education was suddenly disrupted, and universities were mandated to switch to online teaching. The game-based computer app that we designed represents a potentially effective teaching tool for health care students.

Conclusion

This study has provided evidence that SUPER HEMO met our primary objective: to develop an SG for hematology that was playable and acceptable overall. The usability of SUPER HEMO was demonstrated beyond the initial beta-testing pilot study; we obtained preliminary evidence that SUPER HEMO might be a useful educational tool. We will use it as a supplement to lecture-based courses and trace the time and frequency of logins to SUPER HEMO. Last, we propose to correlate this continuous training to student results for the third-year final exams, final graduation exams (at the end of the fifth year), and for the student's specialty choice.

Acknowledgments

We deeply thank all participants and the University of Lorraine for supporting this study, especially Catherine Claus-Demangeon, Edwige Morin, and Hugo Bousquet. We also deeply thank Prof Beatrice Faivre, Prof Raphaël Duval, and Prof Marc Braun. This study was financed by Initiatives d'excellence en formation innovantes – Réseau des écoles de management et d'ingénierie de la santé (IDEFI-REMIS) (ANR #11-IDFI-0033) and the pharmacy and medicine faculties in Nancy.

Abstract

Background: The use of serious games in health care is on the rise, as these games motivate treatment adherence, reduce treatment costs, and educate patients and families. However, current serious games fail to offer personalized interventions, ignoring the need to abandon the *one-size-fits-all* approach. Moreover, these games, with a primary objective other than pure entertainment, are costly and complex to develop and require the constant involvement of a multidisciplinary team. No standardized approach exists on how serious games can be personalized, as existing literature focuses on specific use cases and scenarios. The serious game development domain fails to consider any transfer of domain knowledge, which means this labor-intensive process must be repeated for each serious game.

Objective: We proposed a software engineering framework that aims to streamline the multidisciplinary design process of personalized serious games in health care and facilitates the reuse of domain knowledge and personalization algorithms. By focusing on the transfer of knowledge to new serious games by reusing components and personalization algorithms, the comparison and evaluation of different personalization strategies can be simplified and expedited. In doing so, the first steps are taken in advancing the state of the art of knowledge regarding personalized serious games in health care.

Methods: The proposed framework aimed to answer 3 questions that need to be asked when designing personalized serious games: Why is the game personalized? What parameters can be used for personalization? and How is the personalization achieved? The 3 involved stakeholders, namely, the domain expert, the (game) developer, and the software engineer, were each assigned a question and then assigned responsibilities regarding the design of the personalized serious game. The (game) developer was responsible for all the game-related components; the domain expert was in charge of the modeling of the domain knowledge using simple or complex concepts (eg, ontologies); and the software engineer managed the personalization algorithms or models integrated into the system. The framework acted as an intermediate step between game conceptualization and implementation; it was illustrated by developing and evaluating a proof of concept.

Results: The proof of concept, a serious game for shoulder rehabilitation, was evaluated using simulations of heart rate and game scores to assess how personalization was achieved and whether the framework responded as expected. The simulations indicated the value of both real-time and offline personalization. The proof of concept illustrated how the interaction between different components worked and how the framework was used to simplify the design process.

Conclusions: The proposed framework for personalized serious games in health care identifies the responsibilities of the involved stakeholders in the design process, using 3 key questions for personalization. The framework focuses on the transferability of knowledge and reusability of personalization algorithms to simplify the design process of personalized serious games.

serious game; health care; personalization; domain knowledge; framework; eHealth; cocreation

Introduction

Background

Serious games have a primary objective other than pure entertainment as they seek to educate or train, among others [1,2]. In many domains of health care, serious games have shown positive effects and are increasingly used to motivate treatment adherence, reduce treatment costs, and educate patients and their families on a specific pathology [3-7]. For example, serious games are used for the treatment of mental health disorders, such as anxiety disorders or depression [5,8-10], physical [11-14] or cognitive rehabilitation [15-17], or the education of health professionals and patients [18-22]. Multiple reviews exist on this emerging field that state that serious games can be an effective tool for health, but the research remains in its infancy, limited by design and evaluation challenges [5,10,20,21,23-25].

One of these challenges is the long-term and continuous support of the targeted users. The user's abilities will not only evolve but also based on the user's current context, a different configuration or approach might be called for. Many researchers have indicated the need for a personalized approach in serious games, abandoning the *one-size-fits-all* approach [26-31]. Serious games often fail to sustain long-term retention and treatment adherence if gamification mechanisms are not adaptive and cannot dynamically reengage the user [32,33]. Users lose motivation and games become predictable. Although the primary objective of a serious game is not entertainment, it remains crucial that the game is entertaining to retain user engagement [34]. To create long-term engagement in serious games, a balance between challenge and skill, leading to a state of flow, must be achieved [35].

Games tailored to the user generally result in better performance outcomes for the user, making personalization a key aspect of a successful serious game [36-39]. Different terms, such as adaptability, adaptivity, personalization, contextualization, and customization, are used in the literature to indicate the tailoring of serious games to users. Sajjadi et al [26] introduced the overarching term *individualization* when no distinction between these concepts is necessary. Adapting a serious game to the needs of a user can be done at design time, before starting the game (ie, static personalization), or while playing the game (ie, dynamic personalization).

Adaptability is defined by multiple researchers as the possibility to change an environment based on the user's changing needs, whereas *adaptivity* is the dynamic or automatic adjustment of game elements to the individual's actions or performance [26,29]. *Personalization* is characterized by the, often automatic, adaptation of the game based on the profile or context information of a specific individual user, such as heart rate or age [26]. *Customization* can be seen as changing the system based on the needs of a user group or an individual user, manually or automatically, and is often related to changes in appearance and content [26,40]. Streicher and Smeddinck [29] considered personalization as a specific form of customization, while they saw adaptability and adaptivity as a means to achieve personalization or customization. These concepts refer to the tailoring of the game at run time (ie, before or during gameplay), which differs from the player-centered design in which decisions are made during the design of the game based on the needs of a specific target group [41].

Not only do people learn in different ways and paces and perceive the difficulty level of the game differently, but the game itself is also experienced differently by different people, and not all game elements will work for everyone. In addition, the specific skills of the user might vary and develop over the course of playing the game [26,35,42,43]. The game should therefore be able to respond by adapting to the user, that is, ensuring a state of flow [4,35].

Flow theory models the relationship between the level of challenge in the game and the skill level of the user [44,45]. According to the Flow Model, the user is in a state of flow (ie, total immersion with maximized focus and performance) when the game has a clear goal and the user receives direct feedback on their performance related to this goal [45]. More importantly, to enter this state of flow, or the flow channel, the goal and related challenge level of the game should match the skill level of the user [4,29]. Frustration occurs when the game is too difficult for the perceived skill level and boredom sets in if the user is not challenged sufficiently by the game. Therefore, a serious game should maintain a balance between these parameters, even as the skill level of the users increases throughout the course of the game, to ensure that a state of flow is achieved, as shown in Figure 1. Because people differ and learn at different rates, the serious game should be able to detect and respond to the changing context and skill level of the user [4].

Another disadvantage of current gamified health applications is that the level of customization is often lacking, resulting in gamification that does not take health purposes, changes, or target groups into account [32]. Entertainment games already include different preferences among users by identifying player types using models such as the Bartle Model [46]. However, these models cannot be generalized to serious games because they are too limited. More context or player aspects need to be considered for the personalization of serious games, such as anxiety, stress, learning style, engagement, performance, skill level, and so on [26]. In contrast to the audience of entertainment games, the target audience of serious games is larger, including nongamer types.

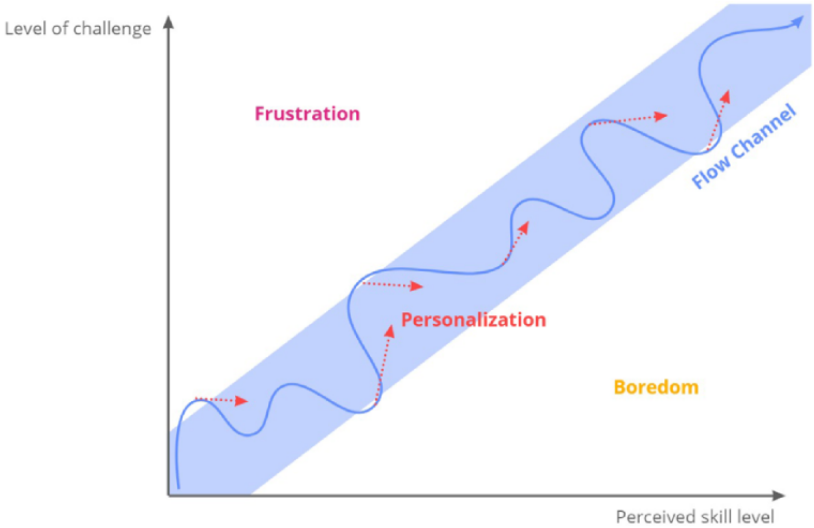
Serious games and gamification, with a user-centered, adaptive, and personalized approach, show promise in increasing treatment adherence and boosting engagement with interventions [3]. Creating a personalized serious game from scratch for each type of user is a costly and challenging operation for developers and domain experts [17,29]. To create a serious game, expert knowledge of relevant domains is necessary. Often, therapists and domain experts are continuously involved in this design process in various ways [28,47]. Some examples are as follows: the involvement of a team of therapists in the design process of a serious game for anxiety reduction in children with autism spectrum disorder [8]; conducting in-depth interviews with occupational therapists for a serious game for cognitive impairment [15]; and validating the content of an informational serious game on COVID-19 by consulting a specialized team of physicians, professors, and medical students [48].

Different methods exist to include personalization in serious games. Some approaches focus on classifying the user according to a certain player type [41,49,50], whereas others focus on changing game aspects [33,35,51]. Rule-based adaptation defines rules that, when satisfied, lead to predefined actions that determine the further course of the game. However, this can lead to a less effective game because adaptation options are limited by the predefined rules [4]. Plan-based adaptation can be considered as a collection of state machines. Each plan is a state machine of which each state is an executable action in the game. If a condition is met, the active states can be selected to determine the course of the game. This adaptation method can, for example, be used in games containing several storylines, unlocking different aspects of the story depending on the user's current physiological state (eg, relaxed vs stressed states) [4]. Model-based adaptation allows the creation of models for various game elements. These models can dynamically change based on the changing user information. This method allows for more complex analysis and adaptation techniques such as the use of artificial intelligence to predict the progression of the user in the future [4,52]. Studies exist on how gamification and serious games can be personalized and which factors influence these decisions [53]. However, it remains unclear how this information can be integrated into the design and implementation of a fully personalized and adaptive serious game.

Research exists on frameworks for the design of serious games; however, these are often designed for specific health care domains, such as physical [13,54-56] or cognitive rehabilitation [15,57,58], or focus on specific technologies, such as emotion recognition and gamification patterns [59,60]; only a few focus on the development of serious games in general [28,61]. Nevertheless, these frameworks often remain vague on how personalization can be achieved, use one specific model for personalization, or do not target personalized serious games [13,60,61]. Moreover, only one study reported the need for reusable serious games components and proposed a serious game framework for reusable intelligent software components (eg, emotion recognition and learning algorithms) [62]. However, this study is limited to the implementation of software components and does not state how domain knowledge and intelligent personalization algorithms can be integrated into the multidisciplinary design process of serious games.

Owing to the lack of standardized frameworks for the design of a (personalized) serious game, the challenging nature of the design process, and the focus on using case-specific guidelines, the evaluation of serious games is often limited and varies widely as different approaches are taken. Research should aim to evaluate the effectiveness of serious games more rapidly and in a controlled setting, focusing on comparing approaches using the same environment [10,17].

Figure 1. The Flow Model states that to enter the flow channel, that is, a state of total immersion and maximized focus and performance, the goal and related challenge should match the skill level of the user [46].



Objective

Overall, when creating a personalized serious game, 3 questions need to be asked:

- Why is the game personalized?
- What parameters can be used for personalization?
- How is the personalization achieved?

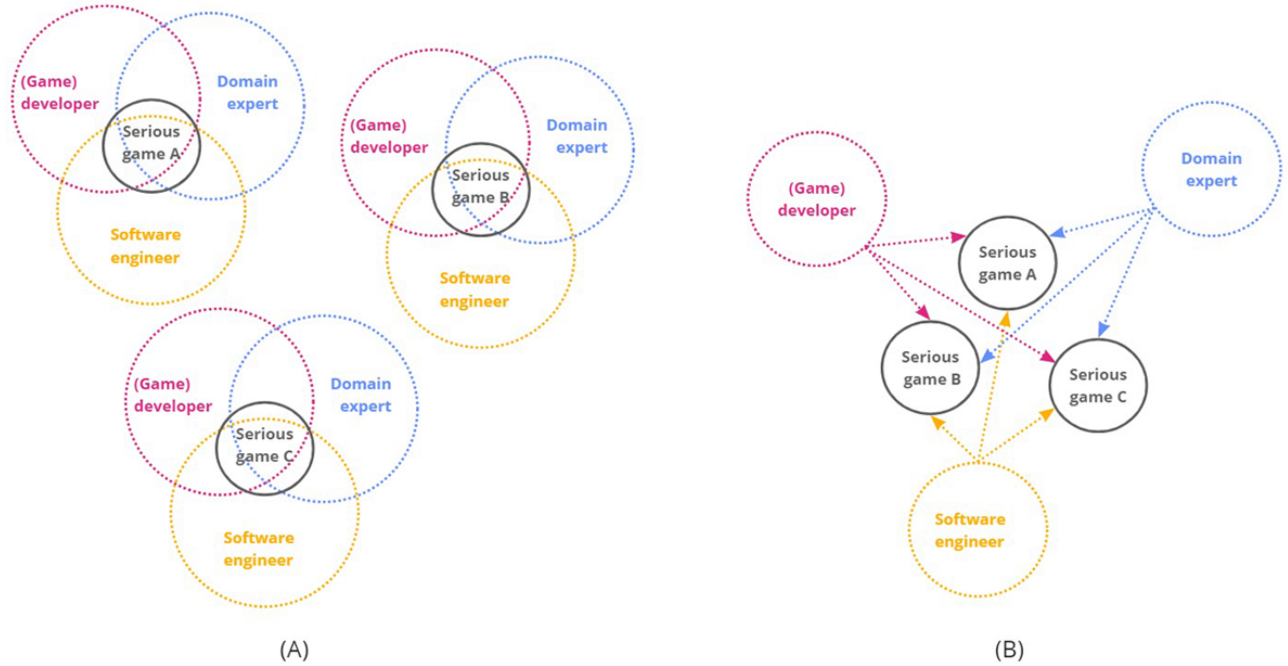
In this study, we aimed to answer these questions by proposing a software engineering framework that streamlines the design process of personalized serious games and facilitates the reuse of domain knowledge and personalization algorithms to reduce development costs.

Currently, the development of personalized serious games is a costly and complex process that requires the continuous involvement of different stakeholders, such as (game) developers, domain experts, and software engineers. Furthermore, this process must be completely repeated for each serious game and is often use-case specific. This means that each stakeholder should share their expertise throughout the design process of each new serious game, irrespective of the subject of the game, as their knowledge is never formalized or transferred to new serious games. This results in a complex process with many dependencies and redundancies between different stakeholders and serious games, which can be visualized as shown in Figure 2A. This approach complicates the evaluation of serious games and personalization strategies. With that many different parameters, such as design approach, target audience, or personalization algorithms, the comparison and evaluation of different personalization strategies are limited. Moreover, very little is known about how personalization strategies can be applied to serious games, as research is focused on the development of serious games for specific use cases, without attention to reusability.

This study aims to reduce these disadvantages by proposing a framework to simplify this process. The framework streamlines the development process of personalized serious games by considering the value of cocreation with different stakeholders, as shown in Figure 2B. However, by focusing on the reusability and formalization and transferability of expert knowledge, the dependencies between the stakeholders can be decoupled, thereby reducing the development cost of a personalized serious game.

The following paragraphs are structured as follows. The *Methods* section describes the *Use and Design of the Software* engineering framework, followed by the *Generic Framework*, which discusses the software engineering framework and the responsibilities of the involved stakeholders. To assess the proposed framework, a simple proof of concept was implemented, that is, an existing game was first transformed into a serious game, which is explained in the *Methods* section in *A Serious Game for ShoulderRehabilitation.* Next, the possibilities of the framework were illustrated by transforming this framework into a personalized serious game in the section *Proof of Concept: an Adaptive and Personalized SeriousGame*, followed by a discussion of the evaluation of the resulting serious game in the *Results* section. Finally, the conclusions of this study are discussed in the *Discussion* section.

Figure 2. (A) A conceptual schematic visualization of the currently complex and redundant dependencies between stakeholders during the development of multiple personalized serious games. (B) Schematic visualization of decoupling these dependencies by implementing reusable components that can be used for multiple serious games, thereby removing the tedious and repetitive effort of the stakeholders.



Methods

Use and Design of the Software Engineering Framework

The proposed framework provides a software engineering perspective on how the design process of serious games can be made more efficient by focusing on personalization and reusability. It can be used to transform existing (serious) games into personalized serious games as well as when designing new personalized serious games. As the proposed framework is a software engineering framework, it acts as an intermediate step between conceptualization and implementation, thereby aiming to close the gap between serious game design and implementation.

The Mechanics, Dynamics, and Aesthetics framework is widely accepted in game design as a formal approach for conceptualizing the dynamic behavior of game systems [63]. It approaches a game from the perspective of the player and discerns mechanics (ie, the actions, goals, and rules of the game), dynamics (ie, the behavior followed by the player's interaction with the mechanics), and the aesthetics (ie, the desired emotional responses of the player when playing the game). The Mechanics, Dynamics, Aesthetics, and Outcomes (MDAO) framework is an extension of the Mechanics, Dynamics, and Aesthetics framework for the conceptualization of serious games [64], and it introduces the concept of outcomes, that is, the behavioral or intellectual responses of the player after playing the game. The MDAO framework approaches a game from the player's perspective by first defining the outcomes and aesthetics, followed by dynamics and mechanics. To define the necessary concepts, a domain expert (outcomes and aesthetics) and a game developer (dynamics and mechanics) are needed. The results of the MDAO framework can then be used in the process of answering the 3 questions the framework poses: Why is the game personalized? What parameters are used for personalization? and How is personalization achieved?

Furthermore, the proposed framework is an extended version of the adaptive experience engine proposed by Bellotti et al [65]. They proposed an architecture that decouples the content of educational tasks from the game aspects in sandbox serious games, that is, games that encourage free play, to standardize the development of educational serious games and increase the efficiency by focusing on the reusability of educational tasks. The adaptive experience engine of Bellotti et al [65] uses educational content or tasks, defined by pedagogical experts, and stores these tasks in a common repository for reuse in different games. A game author is then responsible for specifying the requirements of the delivery of such a task at run time, that is, determining the type of task and time it is relevant during gameplay.

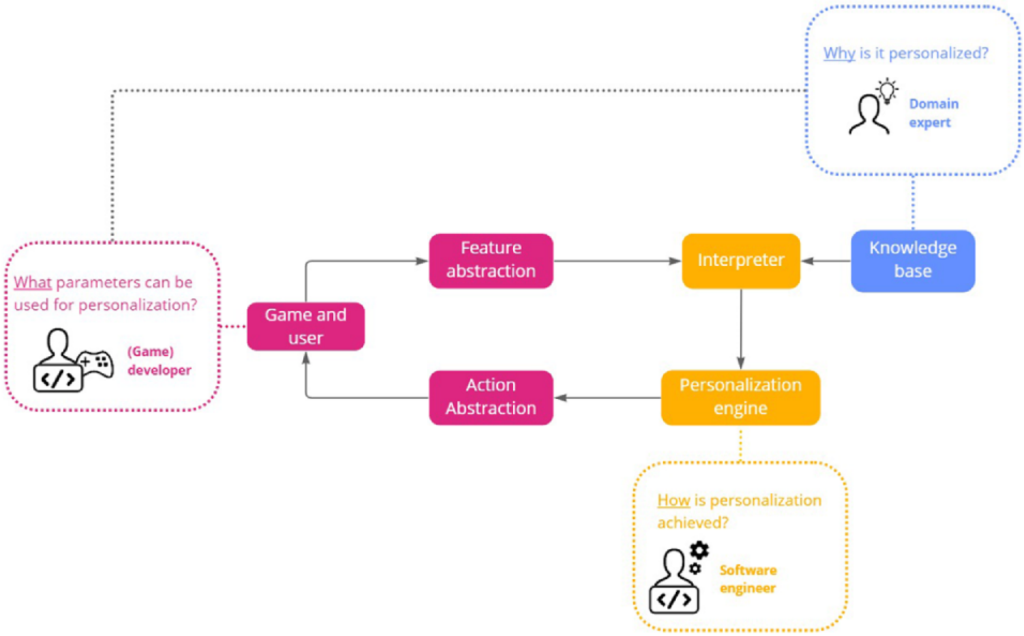
We proposed an extension of this framework for the personalization of serious games for health (SGH). We defined the necessary building blocks to increase the reusability of the different components and assign stakeholder responsibilities to these components. Instead of a repository of educational tasks, a knowledge base, which was designed according to the requirements of the domain experts, was included to model the necessary domain knowledge of a serious game. Furthermore, a personalization engine allows for the inclusion and evaluation of multiple personalization algorithms. The proposed framework was evaluated by implementing a proof-of-concept serious game to validate that the framework meets the expectations of the authors.

Generic Framework

Overview

The framework decoupled the domain knowledge from the personalizable variables in the serious game and personalization algorithms. This allowed the modification or addition of expert knowledge and game concepts independently of each other and the exploration of different personalization strategies without altering the structure of the game itself. The generic architecture discerned 6 modules through which a personalization loop flowed, moving through the different modules to translate user and game data into a specific knowledgeable game task that resulted in the adaptation of the game, as shown in Figure 3.

Figure 3. The generic framework consists of 3 types of modules. The Knowledge Base module formalizes the knowledge of the domain expert. The game-specific modules are the responsibility of the (game) developer and contain the personalized parameters. The final module, the Independent Personalizer, is the responsibility of the software engineer, who implements the algorithms for personalization.



Domain Knowledge

The *Knowledge Base* module is at the heart of the framework and aims to answer the question, *Why is there a need for personalization?* More specifically, this module is responsible for modeling the knowledge of the domain experts that gives insight into the serious aspect of the game. Serious games are defined as games that have objectives other than pure entertainment. For example, in the case of a rehabilitation scenario, this component will contain certain information regarding rehabilitation exercises and the conditions under which they can be executed, for example, injury type, skill level, and rehabilitation progress. For this example, the expert knowledge would indicate that personalized support during rehabilitation is necessary to accommodate different injury types, different phases of the rehabilitation process, skill levels, or more, thereby answering why there is a need for personalization. Such expert knowledge can be modeled or computerized using different approaches, for example, simple approaches such as databases or functions or more complex constructs such as ontologies. The goal of the *Knowledge Base* module is to allow the transferability of knowledge, and the module can thus be reused or replaced based on the domain in which the serious game is situated.

Game-Specific Modules

The 3 modules are game specific, namely, the *Game and User* module, which contains the game itself, and the *Feature Abstraction* and *Action Abstraction* modules, which function as a layer of abstraction between the game and the rest of the system. In consultation with the domain expert, the (game) developer can identify the necessary parameters for personalization, answering the question, *What needs to be personalized?* Two sets of parameters, namely, features and actions, are discerned at design time. First, the information that triggers personalization is defined as a feature. These features can be game information, such as scores, or physiological information collected using wearables (eg, heart rate). These features, which trigger the personalization, introduce a feedback loop in the system to ensure that it is adapted according to the needs of the user. For example, when a score or heart rate is too high, the game might be too exhausting, which should result in the adaptation of the system. In addition, when the user continues to score badly, the game might be too difficult, which in turn will result in the adaptation of the difficulty level. Second, the actions are a set of game parameters that are personalizable based on the context information, such as speed and difficulty level, or more complex constructs, for example, to personalize a storyline. At run time, the features are then periodically sent to the *Feature Abstraction* module, where they are abstracted to a generic format that can be interpreted by the game-independent modules. Existing player-type frameworks, such as the Hexad Framework, can be used to identify the parameters for personalization [64].

Independent Personalizer

Two modules, namely, the *Interpreter* module and the *Personalization Engine*, are game and domain independent and can thus be replaced or reused for the personalization of new or existing games. The software engineer aims to answer the question, *How is personalization achieved?* in these modules without the need to interact with the game itself. The *Interpreter* module interacts with the *Knowledge Base* and the game-specific modules to fetch the necessary information to understand the data it has just received. The module then interprets and translates the data into a format that can be understood using the *Personalization Engine*. This value contains the necessary information for the *Personalization Engine* to determine whether personalization is necessary and the degree of personalization without the need for context information. For example, if the user has an extremely high heart rate in a relaxation game, the *Interpreter* will understand, based on the context and domain knowledge that it receives, that the user's heart rate needs to be lowered and personalization has to be applied accordingly. Next, the *Personalization Engine*, containing one or more models for personalization, applies the action and sends it to the *Action Abstraction* module, a game-specific module that knows the game task that this action maps (eg, changing the speed of the game). In turn, the *Action Abstraction* module sends a game-specific task order to the game, which can then adapt accordingly and complete the personalization loop.

Different approaches for personalization exist, for example, intelligent algorithms such as reinforcement learning or recommender systems. By decoupling the personalization task from the game and domain knowledge, opportunities to explore the utility of different personalization models arise. Within one game, different approaches can be used to process or compare triggers for personalization. Furthermore, existing models can be reused for the development of new serious games, which simplifies and reduces the cost of creating a serious game.

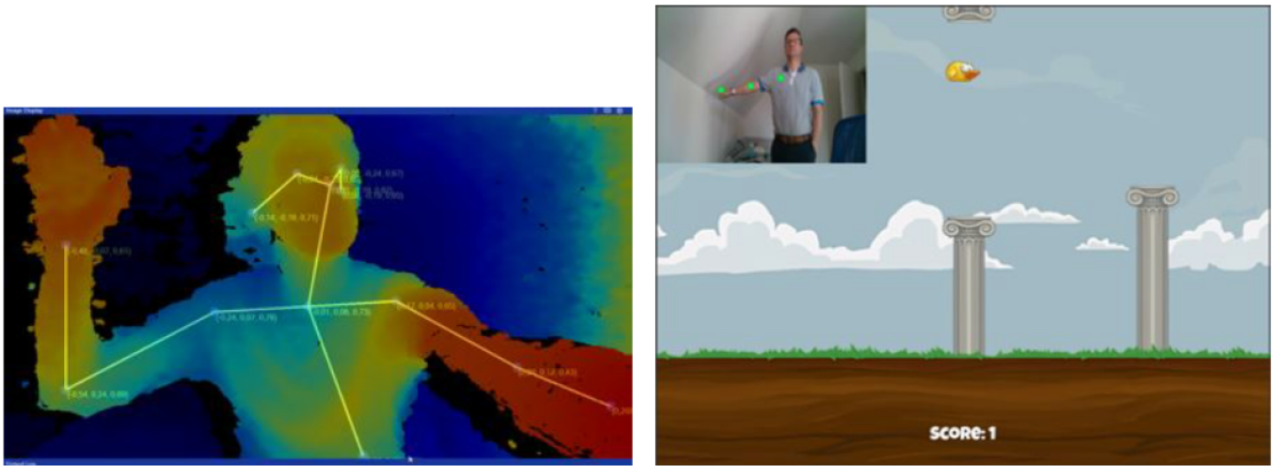
A Serious Game for Shoulder Rehabilitation

In physical rehabilitation, where patients need to repeat exercises regularly to train their mobility or balance, serious games can provide a welcome distraction from the repetitiveness of the treatment. Patients often lack the incentive to complete the time-consuming exercises at home or start rushing through, resulting in a decline in progress and exercise completion and once again demotivating the patient to correctly adhere to the treatment. Serious games for physical rehabilitation aim to motivate patients to increase their treatment adherence and effectiveness.

As a proof of concept, an existing game was transformed into a serious game and then used to illustrate how the proposed framework can be used to personalize existing serious games as well as when designing new serious games. The game was simple and contained a character that could be controlled by pressing a single button to make the character move upward and avoid upcoming obstacles, similar to the well-known game Flappy Bird (Gears). For this research, the game was transformed into a shoulder rehabilitation exercise that was suitable for physical rehabilitation after injury. As mentioned previously, in physical rehabilitation, it is important for patients to perform their exercises regularly and correctly.

The mechanics of the chosen game set the users up for failure, as they must continue controlling the character until it hit an obstacle and the game was over. This seems contradictory, as rehabilitation patients should not be rushed when performing their exercises, and this thus indicates the need for personalization by adapting the difficulty of the game to the capabilities of the user. Instead of controlling the character with a button, the user could control it by lifting their outstretched arm to the shoulder level and moving the character upward. The Intel RealSense Camera (Intel) [66] and the Cubemos skeleton (Intel) tracking SDK [67] were used to track the movement of the arm of the user and control the upward movement of the bird, as shown in Figure 4. The user earned a score based on how long they manage to keep the bird in the air without hitting any obstacles; otherwise, the game ended.

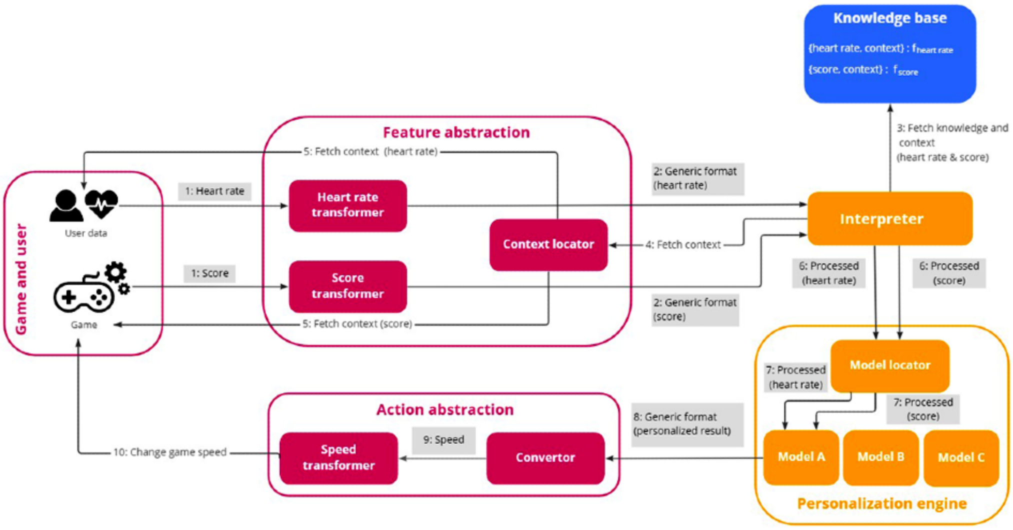
Figure 4. Using the Intel RealSense Camera and the Cubemos skeleton tracking (left), the arm movements of the user are tracked to control the game character (right).



Proof of Concept: an Adaptive and Personalized Serious Game

The following paragraphs discuss the different components of the generic framework in detail, using the implementation of the serious game for shoulder rehabilitation as an illustration of how the framework works. Figure 5 provides an overview of the implemented proof of concept using the proposed framework.

Figure 5. The implementation of the proof of concept using the proposed framework indicates that 2 features have been identified, namely, heart rate and game score. The Knowledge Base contains the necessary expert knowledge and respective context parameters that are necessary to interpret these features. After the Interpreter has interpreted this information, using the Context Locator to fetch the context values, the Personalization Engine is responsible for the adaptation, using the implemented models. Finally, this is again translated to an action of the game, namely, speed.



Domain Knowledge

As mentioned in the section *Generic Framework*, the *Knowledge Base* models the knowledge that is relevant for the specific serious game. This can be achieved using a simple database, storing values, or more complex constructs such as ontologies that are capable of modeling complex relationships between concepts in a computer-readable format. The responsibilities of the domain expert consist of (1) defining or reusing the necessary domain knowledge and, together with the (game) developer, (2) identifying the personalizable parameters of the serious game, that is, features and actions.

For this proof of concept, the *Knowledge Base* was kept simple. The *Knowledge Base* stored 2 functions, one for each identified feature, namely, f_{heart_rate} and f_{score}. The function f_{heart_rate} calculated the highest accepted heart rate for the given context information, whereas the function f_{score} looked at previous N scores, given the necessary context to evaluate the performance of the user. This means that, based on the game and its objective, 2 features were identified, namely, heart rate and game score.

Game-Specific Modules

As previously mentioned, for the game, 2 features were identified, namely, heart rate and game score. These data were collected by the *Game and User* component and were used to trigger the start of the personalization loop as they were periodically sent to the *Feature Abstraction* module, which sent them to the independent personalization modules for evaluation. As patients cannot rush their rehabilitation exercises but should perform them correctly to increase their mobility, the speed of the game was identified as a personalizable action. If the heart rate of the user increased or their game score decreased, the speed of the game should be lowered to continue to ensure good shoulder exercise performance.

Personalization of the game can occur both online (ie, in real time) and offline. For offline personalization, the feature data were only sent after a gaming session, adapting the game for the next session, whereas for real-time personalization, the game was personalized during the gaming session, based on the data received up to that point. One game session was considered to be a level of the game. Both types of personalization have their benefits: real-time personalization allows the game to quickly respond to the user's currently changed context, whereas offline personalization facilitates a more complex analysis that considers the overall performance and progress of the user, instead of just a moment in time.

For each feature, the *Feature Abstraction* module contains its respective *Transformer* module, responsible for translating the data to a generic format, which can be interpreted by the independent personalization modules. Using this generic format, the features can be interpreted by the rest of the system without the need for game-specific information. Nonetheless, these features had very little meaning without the necessary context information. For example, it was difficult to interpret a heart rate of 100 without any additional information. However, given the knowledge that this was the resting heart rate of a 25-year-old male, it was possible to interpret the importance if this heart rate. Therefore, the *Context Locator* module was responsible for providing the relevant context information to the personalization modules when needed. The *Context Locator* knew which context mapped to what features and fetched this information from the *Game and User* module.

This decoupling reduced the integration of a new serious game for personalization to the following steps: (1) identifying the features, (2) identifying the actions, (3) implementing or reusing the respective *Transformer* modules, and (4) creating a *Context Locator* that fetched the relevant context information for the correct feature.

Independent Personalizer

After the *Interpreter* receives the feature data in a generic format, it contacts the *Knowledge Base* to fetch the information to interpret the received value. This information includes the expert knowledge and context parameters that are linked to a specific feature. For the game, the knowledge linked to the heart rate feature was f_{heart_rate} and the relevant context parameters were age, sex, and game intensity. For the score feature, the linked knowledge was f_{score} and the relevant context parameters were the previous N scores.

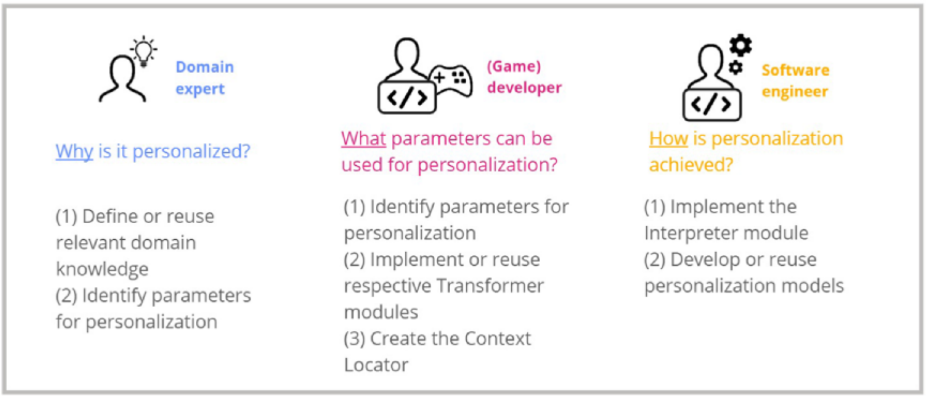
Next, the *Interpreter* module contacts the *Context Locator* to fetch the values of these context parameters for each feature. After receiving all the required information, the *Interpreter* can give meaning to the feature data and transform it into a processed value that contains the necessary information for the *Personalization Engine*, that is, the degree of the needed personalization, but is devoid of any game- or domain-specific knowledge. Continuing the example, the feature data, a heart rate of 100, and the associated context, the resting heart rate of a 25-year-old male, can be interpreted as an unusually high heart rate that should be reduced.

The *Personalization Engine* receives this processed value, and its *Model Locator* sends it to the correct model. As mentioned in the previous section, multiple types of models exist; however, for the proof of concept, only simple rule-based models were implemented to illustrate the framework. The first model receives the processed score as input and is used as an offline adaptation model, that is, the score after each gaming session is processed and used for the adaptation of the speed for the next gaming session. The second model takes the processed score and heart rate as input and is used for offline adaptation, whereas the third model receives the same input but is used for real-time adaptation.

The output of these models is a personalized value that is sent to the *Action Abstraction* module. This module, more specifically, the *Speed Transformer*, performs the reversed action of the *Feature Abstraction* module, as it transforms this generic format into a game-specific format, namely, to an action of the game, that is, speed.

As the *Interpreter* processes these input values, and the *Action Abstraction* module processes the output values, the software engineer does not have to have any domain- or game-specific knowledge to implement personalization algorithms. This reduces the responsibilities of the software engineer in (1) implementing the *Interpreter* module and (2) developing or reusing personalization models. Figure 6 presents an overview of the responsibilities of each of the involved stakeholder.

Figure 6. An overview of the responsibilities of the involved stakeholders.



Results

Simulation of Game Scores

To evaluate the proposed framework, the implementation of a personalized game is assessed using several simulations. First, the response of the system was evaluated when only game scores were used as features. Each score represents the score obtained after a single game. The difficulty level at the start of a gaming session was always 0.8. Adaptation of the speed would only occur after a completed game, that is, offline personalization.

The first series of scores was simulated to show a near-horizontal trend; that is, the user achieved, on average, a constant score for each game. The system used the previous scores of the user to decide whether the difficulty, that is, the speed of the bird, must be personalized. Thus, the difficulty was expected to be increased if this trend continued. Figure 7 shows the simulated scores that were fed to the system (top panel) and the response of the system regarding the adaptation of the difficulty (bottom panel). The gaming scores from the first 10 games showed a more diverging scoring pattern, indicating some drops in the score, and the system responds accordingly by lowering the difficulty. Game 14 showed a substantial increase in the gaming score, followed by a nearly constant score. As shown in the figure, the system reacted to this trend as expected by continuously increasing the difficulty of the game.

A second simulation showed continuously improving game scores, that is, on average, upward trend, as illustrated in Figure 8. As the user continued to improve their previous score, the game was most likely to become too easy for the user. The expected response of the system was to increase the difficulty of the game more visibly during this upward trend than during a nearly constant trend. As of game 16, after a brief drop, the user significantly improved their game scores, upholding an upward trend. As expected, the system countered this by increasing the difficulty significantly faster than during the first 13 sessions, when the user achieved a constant score.

The final simulated game series illustrated the situation in which the performance of the user continued to drop, that is, a downward trend in the game scores, as illustrated in Figure 9. Such behavior might indicate that the game is too difficult for the user and the game should respond by significantly decreasing the difficulty. As of the 16th game, the score of the user kept dropping, to which the system responded, as expected, by decreasing the speed of the game. By game 27, the user reached a new local maximum, which was answered by the system by again a slow increase in difficulty.

Figure 7. The first 10 games show a diverging score (top), which responds to a near-constant difficulty (bottom). The score of the user drops as of game 10, to which the system responds with a drop in difficulty. After game 14, the user achieves, on average, a constant score, which is, as expected, responded to by the system with a slow increase in difficulty.

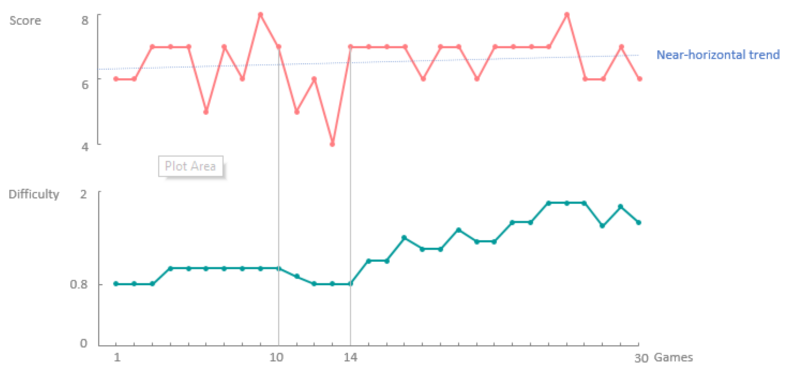


Figure 8. The score of the user is, on average, constant during the first 13 games (above), to which the system responds with a slight increase in difficulty (below). After a brief drop in scores, the user's score indicates an upward trend as of game 16. The system responds by significantly increasing the difficulty of the game as long as this upward scoring trend continues.

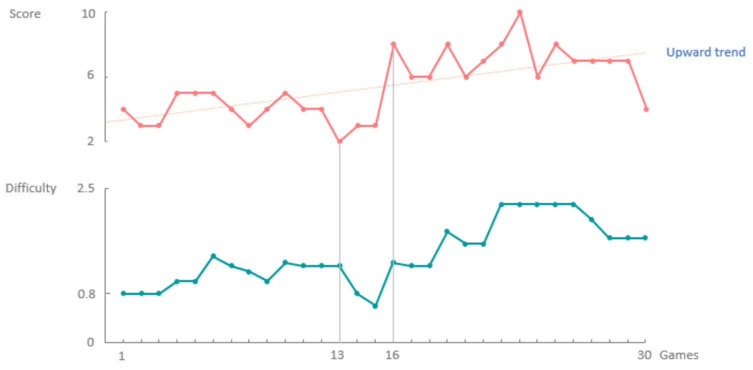

Figure 9. In the first 15 games, the user reaches, on average, a constant score (above), to which the system again responds by slowly increasing the difficulty (below). As of game 16, the score keeps dropping, showing a downward trend, to which the system responds by significantly lowering the difficulty.

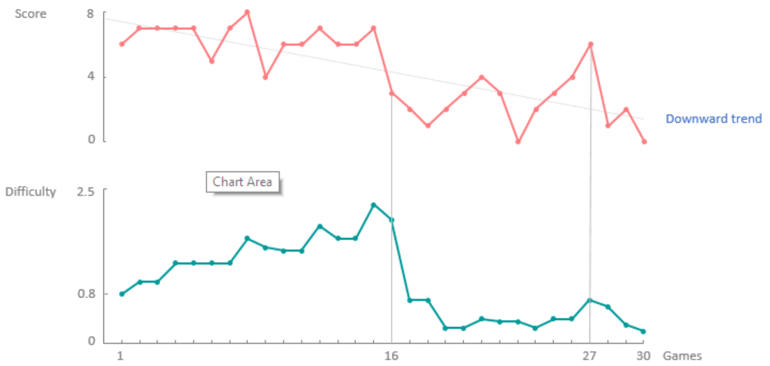

Simulation of Game Scores and Heart Rate

For a second evaluation of the system, game scores and a rising heart rate, which at some point would exceed the set maximum heart rate of 180, were simulated. For this particular use case, where the user should perform a simple arm exercise, an elevated heart rate could indicate that the patient was distressed or experiencing pain, which would negatively affect the obtainable goal, that is, increasing the mobility of the arm. Therefore, the system should respond to this elevated heart rate by adapting to the game. The response of the system was compared for both offline, that is, after a gaming session, and real-time personalization, that is, during a gaming session.

For this simulation, we expected that a high heart rate would have a greater impact on the personalization of the game than the gaming score. If a rising heart rate was detected and the heart rate approached the maximum threshold heart rate of 180, the system should respond by immediately reducing the speed of the game. However, for offline personalization, the system was only able to respond if the average heart rate of the last completed game session exceeded 180. Therefore, the system could only reduce the speed of the game after a completed game session. For real-time personalization, the system was expected to respond much sooner and decrease the speed of the game from the moment the real-time heart rate exceeds the threshold value during the gaming session.

For this evaluation, the constant gaming score from the first simulation (Figure 7) was reused. Figure 10 illustrates the simulated gaming score (above), simulated average heart rate per gaming session (middle), and response of the system for both offline adaptation and real-time adaptation (below). For offline adaptation (green), the difficulty during a gaming session remained constant and was adapted only after the game has been completed. For real-time adaptation (purple), the difficulty could vary during a gaming session as real-time adaptations occurred. The difficulty values illustrated in Figure 10 correspond to the difficulty level at the end of each gaming session.

In the first simulation of a constant game score, the expected behavior was an increase in the difficulty. However, the system then also had to consider a rising heart rate, which resulted in more or less constant difficulty as long as the heart rate continued to rise. For offline adaptation, as soon as the average heart rate of a game session crossed the threshold value, which was the case for game 27, the system responded by decreasing the difficulty. Because offline adaptation introduced a certain delay, the game could only respond by game 28. The figure shows that this delay was not visible in the case of real-time adaptation, as the difficulty had already decreased for game 26.

Figure 11 provides a detailed overview of how the system reacted (below) to the real-time heart rate (above) during games 26 to 30. Here, it is clear that the user's heart rate already exceeded the threshold value during game 26, and thus the system could immediately reduce the difficulty of the game in the case of real-time adaptation. Because of the rigidity of offline adaptation, that is, one set speed for an entire game, the difficulty also decreased more slowly compared with real-time adaptation. The minimum difficulty for offline personalization of the entire exercise session was reached in game 30, whereas this minimum was already reached in game 27 using real-time personalization, reaching an even lower speed by the end of game 30.

Figure 10. For an, on average, constant score (above) and a constantly increasing heart rate (middle), the system responds differently for real-time personalization compared with offline personalization (below). If the system is updated after the game (offline personalization), the maximum threshold heart rate of 180 bpm is exceeded in game 27, of which the average heart rate is 182 bpm. The system thus starts decreasing the difficulty as of game 28. When the system is updated during the game (real-time personalization), the system already decreases the difficulty as of game 26, therefore achieving a much lower speed much faster. bpm: beats per minute.

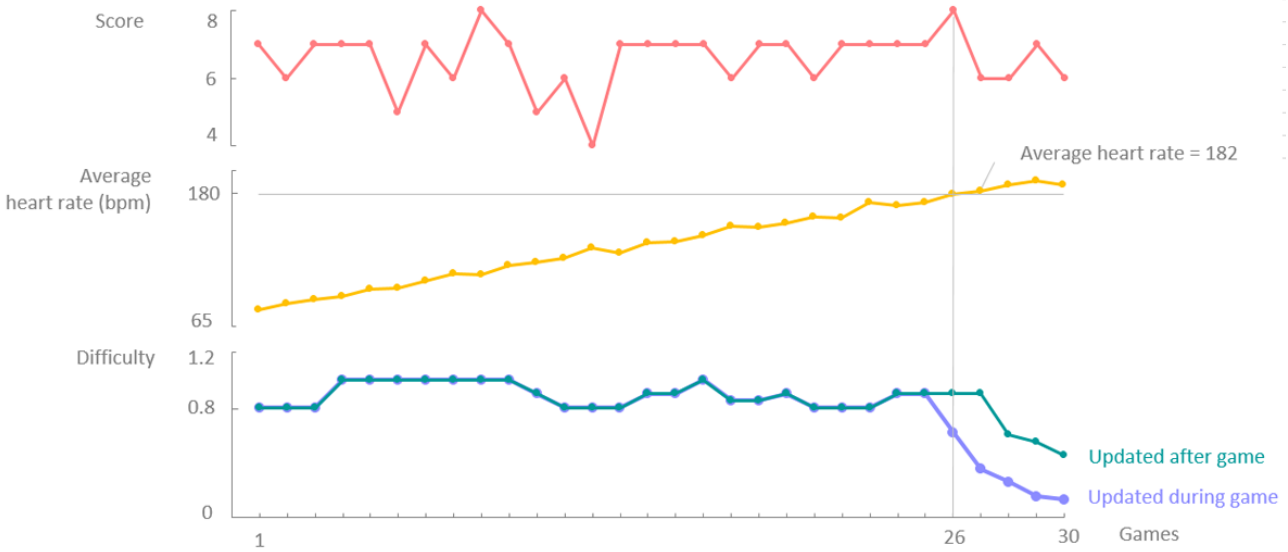

Figure 11. This detailed overview of the heart rate of the user starting from game 26 (top) indicates that the system can reduce the difficulty of the game (bottom) much faster in the case of real-time adaptation as the maximum threshold of 180 is already exceeded in game 26. Because the average heart rate of a gaming session only exceeds 180 in game 27, a delay is introduced in the version using offline adaptation. Real-time adaptation, therefore, allows the system to respond much faster to critical values than when offline personalization is used.

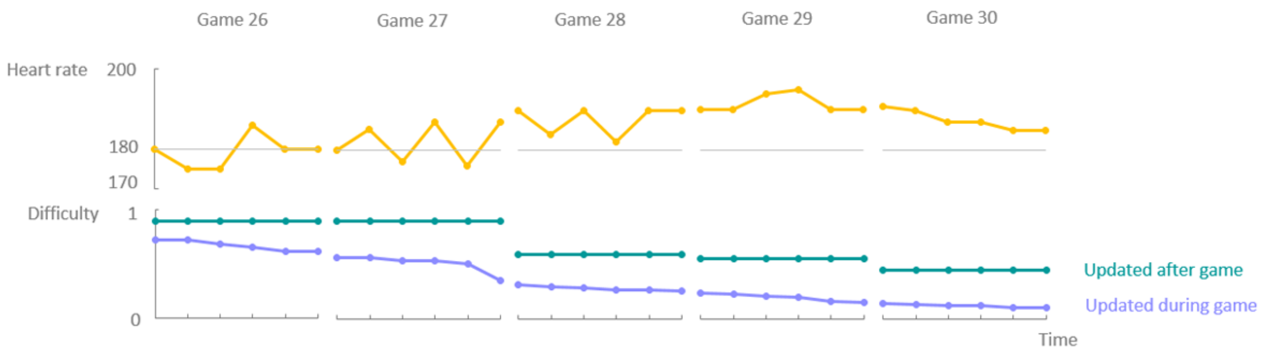

Discussion

Principal Findings

This study proposes a framework to standardize and simplify the design of personalized SGH. The process of designing a serious game is challenging and involves multiple stakeholders. The proposed framework identifies the responsibilities of the involved stakeholders using 3 key questions. The framework focuses on the reusability, formalization, and transferability of the expertise of these stakeholders to simplify this process. As a proof of concept, a simple game was transformed into a serious game for shoulder rehabilitation. The game was implemented according to the proposed framework to illustrate how it can streamline the design and implementation of personalized serious games. Several simulations were conducted to evaluate the personalization mechanics of the resulting personalized serious game.

The integration of the framework introduces several advantages for the design of personalized serious games. First, by assigning responsibilities to the stakeholders involved, the cocreation of the serious game is still respected, but the complicated process is simplified. Each stakeholder knows what is expected of them and with whom they need to communicate to receive specific information. By introducing 3 types of modules, namely, domain knowledge, game-specific modules, and an *Independent Personalizer*, and defining the communication between these modules, the reusability of these modules becomes possible, introducing a sort of “plug-and-play” structure of the components. Domain knowledge can be formalized using complex structures, such as ontologies or a simple information database, and can be reused or extended to multiple serious games. Over time, researchers can gather an extensive knowledge base covering one or more domains, each time reducing the effort needed to integrate their knowledge into a new serious game. A similar approach can be adopted for the other modules.

Furthermore, this framework allows for the integration of multiple personalization algorithms or approaches. As discussed in the *Introduction* section, different methods exist for the personalization of serious games, but very little is known about their effectiveness. Using this framework, software engineers can focus on further developing and evaluating these personalization approaches without the need to repeat the entire process from scratch. Thus, more effort can be directed toward developing more complex and intelligent algorithms. However, the framework allows not only the reusability of algorithms but also multiple algorithms to be used simultaneously for one serious game, as the *Personalization Engine* can contain multiple models for the identified features. This can be interesting when both real-time and offline personalization needs to be considered. Serious games in the health care domain often deal with gathering time-sensitive information, collecting health sensor data, or monitoring the performance of the user, and wrong movements can have detrimental effects. The framework allows the integration of specialized personalization models that monitor these data and intervene instantaneously when needed without the need to interrupt the rest of the personalized game mechanics, as these models can exist independently of one another.

Finally, the literature has shown that the evaluation of the effectiveness of serious games is often inadequate because of sparse evaluation results, lack of standardized evaluation approaches, and high cost of designing serious games. This framework takes the first steps toward a more accessible and standardized evaluation procedure for serious games. The framework easily allows the control of different parameters by interchanging the components under evaluation, such as personalization algorithms, and reusing other components. Moreover, because of the reusability of components, different personalization strategies for serious games can be tested and evaluated at a much faster pace.

Future Work

Although this study offers many contributions, it has some limitations that will be addressed in future work. First, the complexity of the proof of concept is limited to illustrating the functioning of the framework. Second, the resulting personalized serious game was evaluated using simulations. Therefore, future work will focus on implementing a more complex knowledge base and intelligent algorithms. Using this framework will facilitate the evaluation and comparison of different artificial intelligence algorithms, such as recommender systems or machine learning algorithms. The resulting serious game will be assessed using large-scale evaluations with end users to ensure that the personalization strategies used fit the needs of the target audience. To this end, questionnaires such as the System Usability Scale [68] and the Gameplay Scale [69] will be essential for thorough evaluation.

Conclusions

We proposed a framework for the design of personalized SGH. The aim of this framework is to offer guidelines that streamline the complex cocreation process of serious games. Moreover, the implementation of this framework facilitates the transferability of domain knowledge and reusability of personalization algorithms, thereby taking the first steps to the state of the art concerning personalization in SGH. Complex models of specific domain knowledge can be reused and extended, while different personalization strategies can be easily compared and evaluated.

Authors' Contributions

SC, VN, and FDB conceptualized the study. SC and VN designed the methodology; were responsible for validation, formal analysis, investigation, and curation; and wrote the original draft. VN procured the software. SC visualized the data. SC, VN, FDB, and FDT reviewed and edited the manuscript. FDT supervised the study. All the authors have read and agreed to the published version of the manuscript.

Abstract

Background: China has continuously issued policies to speed up the interconnection, mutual recognition, sharing of medical information systems, and data integration management across regions and institutions. However, the vertical integration of electronic health records (EHRs) within the medical consortium is hampered by "poor mechanism and insufficient motivation" and the phenomenon of "free riding" among participating medical institutions, which makes the integration less effective.

Objective: We hope to clarify the game mechanism of stakeholders in the vertical integration of EHRs, and put forward targeted policy suggestions for improvement.

Methods: We constructed the "government-hospital-patient" tripartite evolutionary game model based on the detailed analysis of the research problems and their assumptions. We then simulated the game strategies and outcomes of each participant using the system dynamics approach to reveal the long-term strategy evolution mechanism of the core participants in the vertical integration of EHRs in the medical consortium, as well as the influencing factors and action mechanisms of each party's strategy evolution to provide references for improving relevant policies.

Results: The evolutionary game system could eventually reach an optimal equilibrium, but in areas where the government was required to be in a dominant position, patient supervision was necessary to have a positive role, while a reasonable reward and punishment mechanism can promote active participation of hospitals.

Conclusions: The effective way to achieve the goal of vertical integration of EHRs in the medical consortium is to build a multiagent coordination mechanism under the guidance of the government. Meanwhile, it is necessary to establish a scientific integration performance evaluation mechanism, a reward and punishment mechanism, and a benefit distribution mechanism to promote the healthy development of vertical integration of EHRs in medical consortiums.

KEYWORDS

medical consortium; EHRs; evolutionary game; system dynamics; medical information resources

Introduction

The construction of a medical consortium is an important institutional innovation to deepen medical reform and a specific practical path to achieve graded diagnosis and treatment, which plays a vital role in the reform and development of medical and health undertakings in China. It is generally believed that a medical consortium is a medical service community with high-level medical institutions (tertiary hospitals) as the core institution (also named the leading unit) and other medical and health institutions at various levels in the region united as participating units (also known as member units) to vertically integrate medical and health resources, thereby eliminating fragmentation of medical services and achieving integration of services, responsibilities, benefits, and management [1]. The accessibility, continuity, and radiation of medical services are enhanced, and the quality and efficiency are improved, via the integration of cross-regional and cross-level medical services, resources, technologies, and information [2]. Since the promulgation of the "Pilot Work Plan for the Construction of Urban Medical Consortium" [3], relevant policies have repeatedly emphasized strengthening the integrated management of medical consortiums, realizing the continuous recording of electronic health records (EHRs) and electronic medical records, and gradually realizing the effective sharing of medical and health information within the medical consortium, to improve the efficiency of treatment and reduce medical costs. The "14th Five-Year Plan for the Implementation of Quality and Efficient Medical and Health Services," released in July 2021 [4], also includes accelerating the interconnection, mutual recognition, and sharing of cross-regional and cross-institutional information systems, as well as data integration and management as key projects. The construction of a medical consortium has thus become an important strategic measure to build an integrated medical and health service system in China.

EHRs refer to the systematic digital record of health information, such as disease treatment, immunization, chronic disease management, genetic history, throughout the life cycle of individual citizens through a variety of collection channels. The existing EHRs are scattered in different medical and health institutions at all levels, which seriously restricts the healthy and orderly development of a medical consortium. The vertical integration of EHRs refers to the collection, sorting, and ordering of EHRs among medical institutions at different levels within a medical consortium [5]. The purpose of EHRs is to break the decentralized pattern, promote the collaboration and hierarchical diagnosis and treatment within the medical consortium, promote the in-depth cooperation and organizational collaboration within the medical consortium, and help the development of the medical consortium from loose to compact. The integration of medical information resources has always been the core of medical and health information research. Although existing studies focused on the integration of diagnosis and treatment information resources within medical institutions, attention given to the integration and sharing of EHRs across institutions is far from adequate. The reasons for this are as follows: (1) the policies related to the integration of medical consortium and EHRs have not been proposed for a long time, and the policy effect has not been fully manifested; and (2) the shackles of "poor mechanism and insufficient motivation" are deeply rooted in the integration of medical resources across institutions, and the phenomenon of "free riding" by participating medical institutions is prominent, which makes the integration ineffective.

The game theory is suitable for the study of multiagent behavior. Evolutionary game is favored because its bounded rationality assumption of game players is more realistic, which is widely used in various fields, such as multiple governance, organizational coordination, and information behavior. Cross-institutional information resource sharing often involves many stakeholders, and it could gradually approach the evolutionary stable state after repeated games. Some studies have tried to use the evolutionary game method to perform relevant research in the medical and health field, such as studying doctor-patient disputes under government regulation [6], evolutionary game of a 2-way referral mechanism [7], emergency management of public emergencies [8], knowledge sharing in online health communities [9], drug safety and public health quality supervision [10,11], and integrated health care systems [12]. Some studies also use evolutionary game and simulation methods to explore the willingness of medical data sharing, but these only consider the 2 parties of patients and medical service institutions [13], and fail to consider the willingness and influence mechanism of cross-agency data sharing of the government and other multiparties under the organization mode of the medical consortium. The government, hospitals, and patients are the 3 direct stakeholders involved in the vertical integration of EHRs. To make all parties act in a unified manner in order to achieve the collective goal of resource integration, it is necessary to understand the long-term game strategy and its evolutionary stability of all parties. In addition, most previous studies used qualitative analysis methods such as speculative reasoning, expert interviews, or text analysis, and few studies used mathematical methods to discuss the issues shared by EHRs across institutions.

The essence of cross-organizational EHRs integration within a medical consortium is not a technical implementation but an organizational synergy problem, the core of which is the progressive evolutionary game problem of multiple stakeholders. In particular, participating medical institutions and patients have more evolutionary characteristics of progressive learning, and government behavior affects the development direction of EHRs integration. In this paper, we used evolutionary game analysis to incorporate the government, hospitals, and patients into a system model to explore the long-term strategy evolution of the 3 parties in the vertical integration of cross-organizational EHRs within a medical consortium, as well as the influencing factors and mechanisms of each party's strategy evolution. Finally, we proposed corresponding countermeasures based on data simulation using system dynamics. The findings of the study can provide a reference basis for the smooth implementation of vertical integration of EHRs within a medical consortium.

Methods

Construction of an Evolutionary Game Model

Problem Statements and Assumptions

From the perspective of stakeholders, the core participants involved in the vertical integration of EHRs are mainly the government, hospitals, and patients. As the main driving force of the hierarchical diagnosis and treatment system, the government has made every effort to promote the vertical integration of EHRs in the medical consortium through top-level design and the introduction of relevant policies to optimize the allocation of medical resources. However, local governments may make every effort to promote it or treat it negatively, due to the impact of protectionism, high costs, human resources, and complexity of implementation. Therefore, the behavior strategies of the local government are either "trying to promote it" or "treating it negatively."

Hypothesis 1

For local governments, if they try their best to promote the integration of EHRs, the income, such as social value, public praise, superior rewards, will be R_g and the cost will be C_g; when the local government takes a negative attitude, it will neither give subsidies or rewards to the hospitals and patients nor impose penalties. The cost is K_g (C_g>K_g) in such cases, and the local government will be punished as F_g (including the accountability of the superior government, government credibility, and reputation loss). When the hospital actively participates in the information integration under the policy effect and achieves good results in practice, the boundary between the local government's "efforts to promote" and "negative treatment" will become very vague. Therefore, the local government will not be held accountable by the superior government, nor will there be potential punishment such as loss of credibility and reputation.

As the owner of EHRs, hospitals' participation attitude directly affects the success or failure of the vertical integration of EHRs. Existing research shows that the leading large hospitals worry about weakening the absolute dominant position of medical resources, while the small hospitals participating in the medical consortium may negatively treat the integration of information resources to maintain their own economic interests and social reputation [14]. However, both the leading hospitals and member units may actively respond to national policies, abandon "free riding" opportunism, and actively participate in the vertical integration project of EHRs. Therefore, the behavior strategies of the hospital are active participation or passive participation.

Hypothesis 2

For the hospital, the revenue under normal operation is R_h. If the hospital actively participates in the sharing and utilization of cross-institutional EHRs, the reward subsidy from the superior government is F_h, and the cost is C_h. If the hospital chooses a negative strategy, its cost is K_h (C_h>K_h), and the resulting damage to the overall social interests is R_p, which will be borne by the public (especially patients). When patients find that their EHRs cannot be shared and utilized across institutions, if they complain to the superior supervision organization, the hospital will be punished as M_h. If the patients do not choose to complain, no supervision cost will be incurred.

As the biggest beneficiary of the hierarchical diagnosis and treatment system, the patients have the right and obligation to supervise and complain about the interconnection and availability of EHRs in the medical consortium. The patients may supervise hospital behaviors to protect their own rights and interests and complain to the medical and health supervision department, but they may also give up their right to supervision because of negative ideas such as "It's better to save trouble" and "supervision is the same as non-supervision" or because they think that the supervision cost is too high. Therefore, the behavior strategy space of patients is participating in supervision or giving up supervision.

Hypothesis 3

For patients, the cost of active participation in supervision is C_p, and the reward from the government is F_p; if patients give up supervision, they will neither incur costs nor receive government incentives.

The behaviors of local governments, hospitals, and patients all conform to the bounded rationality hypothesis of the evolutionary game theory. In the game process, each party continuously adjusts its own strategies through the behaviors of the other 2 parties, and finally reaches a stable state after repeated games.

Construction of a Tripartite Profit Matrix

Assuming that the ratio of local government choosing to promote is x, the ratio of its negative treatment is $1 - x$. If the rate of active participation is y, the rate of passive participation is $1 - y$. If the rate of patients choosing supervision complaints is z, the rate of giving up supervision is $1 - z$, and $x, y, z \in [0, 1]$. The relevant parameter settings and their meanings are shown as Table 1.

According to the aforementioned analysis and assumptions, the game payoff matrix of the 3 core players in the vertical integration of EHRs in the medical consortium under different strategic combinations is shown in Table 2.

Table 1. Relevant parameters setting and their meanings.

Parameters	Meanings
R_g	Benefits when the local government tries to promote EHR[a] integration
C_g	Costs when the local government pushes hard
K_g	Costs when the local government treats EHR integration negatively
F_g	Punishment received when the local government treats EHR integration negatively
R_h	Revenue when the hospital is in normal operation
C_h	Costs when hospitals are actively involved in EHR integration
K_h	Costs when hospitals are passively involved in EHR integration
F_h	Government subsidies when hospitals actively participate in EHR integration
M_h	Punishment when the hospital participates passively in EHR integration
F_p	Rewards received when patients actively participate in supervision
C_p	Costs when patients actively participate in supervision
R_p	Social damage caused by negative hospital participation

[a]EHR: electronic health record.

Table 2. Evolutionary game payoff matrix of the local government, hospital, and patient.

Game players	Local governments	
	Push hard (x)	Negative treatment ($1 - x$)
Hospital		
Actively participation (y)		
Patient		
Participation in supervision (z)	$R_g - C_g - F_h - F_p, R_h - C_h + F_h, F_p - C_p$	$-K_g, R_h - C_h, -C_p$
Waiver of supervision ($1 - z$)	$R_g - C_g - F_h, R_h - C_h + F_h, 0$	$-K_g, R_h - C_h, 0$
Passive participation ($1 - y$)

Waiver of supervision ($1 - z$)	$R_g - C_g + M_h, -K_h - M_h, -R_p$	$-K_g - F_g, -K_h, -R_p$

Behavior Equilibrium Analysis of Evolutionary Game

Expected Profit of Game Players

Let E_{g1} be the expected return when the government pushes hard, E_{g2} be the expected return when the government treats EHR integration negatively, and E_g be the average return under the 2 strategies of the government pushing hard and treating negatively, then:

$$E_g = xE_{g1} + (1 - x)E_{g2} \quad \textbf{(1)}$$

$$E_{g1} = yz(R_g - C_g - F_h - F_g) + y(1 - z)(R_g - C_g - F_h) + z(1 - y)(R_g - C_g + M_h) + (1 - y)(1 - z)(R_g - C_g + M_h) \quad \textbf{(2)}$$

$$E_{g2} = yz(-K_g) + y(1 - z)(-K_g) + z(1 - y)(-K_g - F_g) + (1 - y)(1 - z)(-K_g - F_g) \quad \textbf{(3)}$$

Let E_{h1} be the expected benefit when the hospital actively participates, E_{h2} be the expected benefit when the hospital passively participates, and E_h be the average benefit in both cases of active and passive hospital participation, then we have:

$$E_h = yE_{h1} + (1 - y)E_{h2+} \quad \textbf{(4)}$$

$$E_{h1} = xz(R_h - C_h + F_h) + x(1 - z)(R_h - C_h + F_h) + z(1 - x)(R_h - C_h) + (1 - x)(1 - z)(R_h - C_h) \quad \textbf{(5)}$$

$$E_{h2} = xz(-K_h - M_h) + x(1 - z)(-K_h - M_h) + z(1 - x)(-K_h) + z(1 - x)(-K_h) + (1 - x)(1 - z)(-K_h) \quad \textbf{(6)}$$

Let E_{p1} be the expected benefit when the hospital actively participates, E_{p2} be the expected benefit when the hospital passively participates, and E_p be the average benefit in both cases of active and passive hospital participation, then we have:

$$E_p = zE_{p1} + (1 - z)E_{p2} \quad \textbf{(7)}$$

$E_{p1} = xy(F_P - C_P) + y(1 - x)(-C_P) + x(1 - y)(F_P - C_P - R_P) + (1 - x)(1 - y)(-C_P)$ **(8)**

$E_{p2} = x(1 - y)(-R_p) + (1 - x)(1 - y)(-R_p)$ **(9)**

Replication Dynamic Equation of Game Players

Replication dynamic equations can not only reflect the speed of evolution, but also determine the direction of decision evolution of game players. According to the calculation method proposed by Friedman [15], we constructed the replication dynamic equation under the active state of each game player.

Combining equations 1-3, we could construct the replication dynamic equation when the government tries to promote EHR integration as follows:

$F(x) = dx/dt = x(E_{g1} - E_g) = x(1 - x)(Eg_1 - E_{g2})$

$= x(1\text{-}x)\{[yz(R_g - C_g - F_h - F_p) + y(1 - z)(R_g - C_g - F_h) + z(1 - y)(R_g - C_g + M_h) + (1 - y)(1 - z)(R_g - C_g + M_h)] - [yz(-K_g) + y(1 - z)(-K_g) + z(1 - y)(-K_g - F_g) + (1 - y)(1 - z)(-K_g - F_g)]\}$

$= x(1 - x)[(R_g + F_g + M_h + K_g - C_g) - y(zF_p + F_g + F_h + M_h)]$ **(10)**

Combining equations 4-6, the replication dynamic equation for active hospital participation could be constructed as follows:

$F(y) = dy/dt = y(Eh_1 - E_h) = y(1 - y)(Eh_1 - Eh_2)$

$= y(1 - y)\{[xz(R_h - C_h + F_h) + x(1 - z)(R_h - C_h + F_h) + z(1 - x)(R_h - C_h) + (1 - x)(1 - z)(R_h - C_h)] - [xz(-K_h - M_h) + x(1 - z)(-K_h - M_h) + z(1 - x)(-K_h) + (1 - x)(1 - z)(-K_h)]\}$

$= y(1 - y)[(R_h + K_h - C_h) - x(F_h + M_h)]$ **(11)**

Similarly, combining equations 7-9, the replication dynamic equation could be constructed when the patient is actively supervised as follows:

$F(z) = dz/dt = z(Ep_1 - E_p) = z(1 - z)(Ep_1 - Ep_2)$

$= z(1 - z)\{[xy(F_p - C_p) + y(1 - x)(-C_p) + x(1 - y)(F_p - C_p - R_p) + (1 - x)(1 - y)(-C_p)] - [x(1 - y)(-R_p) + (1 - x)(1 - y)(-R_p)]\}$

$= z(1 - z)[x(F_p - R_p - yR_p)+(1 - y)R_p - C_p]$ **(12)**

Equilibrium Analysis of the Evolutionary Game System

Combining equations 10-12, we can get the 3D dynamic system of the game participants (ie, the government, hospitals, and patients), which is given as follows:

$F(x) = dx/dt = x(1 - x)[(R_g + F_g + M_h + K_g + C_g) - y(zF_p + F_g + F_h + M_h)]$

$F(y) = dy/dy = y(1 - y)[(R_h + K_h - C_h) + x(F_h + M_h)]$

$F(z) = dz/dt = z(1 - z)[x(F_p - R_p + yR_p) + (1 - y)R_p - C_p]$ **(13)**

By making the 3 replicated dynamic equations in equation (13) equal to 0, we can obtain 8 pure strategies Nash equilibrium solutions of the evolutionary game system, namely, (0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 0, 1), (1, 1, 0), and (1, 1, 1). Existing studies in the field have proved that only the stability of the aforementioned 8 local equilibrium points can be considered in the analysis of a 3-party evolutionary game [16], and that it is not necessary to consider the Nash equilibrium solution *E* (*x**, *y**, *z**) of the mixed strategy. The sign of Jacobian matrix can be used to judge whether the aforesaid 8 local equilibrium points are the evolutionary stability strategy of the system, and the condition is det(*J*)>0 and tr(*J*)<0. The Jacobian matrix can be obtained by solving the partial derivatives of the 3 equations in equation (13) with respect to *x*, *y* and *z*, respectively:

$J_{11} = (1 - 2x)[(R_g + F_g + M_h + K_g - C_g) - y(zF_p + F_g + F_h + M_h)];$

$J_{12} = -x(1 - x)(zF_p + F_g + F_h + M_h);$

$J_{13} = -xy(1 - x)F_p;$

$J_{21} = y(1 - y)(F_h + M_h);$

$J_{22} = (1 - 2y)[(R_h + K_h - C_h) + x(F_h + M_h)];$

$J_{23} = 0;$

$J_{31} = z(1 - z)(F_p - R_p + yR_p);$

$J_{32} = -z(1 - z)(1 - x)R_p;$

$J_{33} = (1 - 2z)[x(F_p - R_p + yR_p) + (1 - y)R_p - C_p];$

$\det(J) = J_{11}J_{22}J_{33} + J_{12}J_{23}J_{31} + J_{13}J_{21}J_{32} - J_{13}J_{22}J_{31} - J_{12}J_{21}J_{33} - J_{11}J_{23}J_{32} = xzy^2(1 - x)^2(1 - y)(1 - z)(F_h + M_p)F_pR_p + xyz(1 - x)(1 - 2y)(1 - z)(F_p + yR_p - R_p)[-C_h + K_h + R_h + x(F_h + M_h)]F_p + xy(1 - x)(1 - y)(1 - 2z)(F_h + M_h)[(-C_p + (1 - y)R_p + x(F_p + yR_p - R_p)](F_g + F_h + zF_p + M_h) + (1 - 2x)(1 - 2y)(1 - 2z)[-C_p + (1 - y)R_p + x(F_p + yR_p - R_p)][-C_h + K_h + R_h + x(F_h + M_h)][-C_g + F_g + K_g + M_h + R_g - y(F_g + F_h + zF_p + M_h)]$ **(14)**

$\text{tr}(J) = J_{11} + J_{22} + J_{33} = (1 - 2x)[-C_g + F_g + K_g + M_h + R_g - y(F_g + F_h + zF_p + M_h)] + (1 - 2y)[-C_h + K_h + R_h + x(F_h + M_h)] + (1 - 2z)[-C_p + (1 - y)R_p + x(F_p + yR_p - R_p)]$ **(15)**

The det(*J*) and tr(*J*) values of 8 local equilibrium points can be calculated from equations 14 and 15 and judgment conditions, as shown in Table 3.

So far, the evolutionary game system has achieved the stable state under certain conditions. However, it can be seen from Table 3 that the det(*J*) and tr(*J*) values are determined by the values of many parameters. The existing conditions and calculation methods make it difficult to determine whether the aforesaid 8 equilibrium points are the evolutionary stability strategy, which indicates that it is not clear whether there are equilibrium points in the evolutionary game system. System dynamics can analyze the complex dynamic evolution process of evolutionary game models under the conditions of bounded rationality and asymmetric information [17], and can explore and reveal the potential mechanism of problems and seek key strategies to solve problems [18]. Therefore, we further use the system dynamics tool to simulate the impact of uncertainty factors on the stability of the evolutionary game system, so as to provide decision-making reference for formulating relevant policies and optimizing the dynamic mechanism of EHRs integration.

Table 3. The det(J) and tr(J) of the Jacobian matrix.

Equilibrium point	Det(J)	Tr(J)
(0, 0, 0)	$(R_p - C_p)(K_h + R_h - C_h)(F_g + K_g + M_h + R_g - C_g)$	$F_g + K_g + K_h + M_h + R_g + R_h + R_p - C_g - C_h - C_p$
(0, 0, 1)	$(C_p - R_p)(K_h + R_h - C_h)(F_g + K_g + M_h + R_g - C_g)$	$C_p + F_g + K_g + K_h + M_h + R_g + R_h - R_p - C_g - C_h$
(0, 1, 0)	$-C_p(C_h - K_h - R_h)(K_g + R_g + C_g - F_h)$	$C_h - C_p - F_h + K_g - K_h + R_g - R_h - C_g$
(0, 1, 1)	$C_p(C_h - K_h - R_h)(K_g + R_g - C_g - F_h - F_p)$	$C_h + C_p - F_h - F_p + K_g - K_h + R_g - R_h - C_g$
(1, 0, 0)	$(F_p - C_p)(C_g - F_g - K_g - M_h - R_g)(F_h + K_h + M_h + R_h - C_h)$	$C_g - C_h - C_p - F_g + F_h + F_p - K_g + K_h - R_g + R_h$
(1, 0, 1)	$(C_p - F_p)(C_g - F_g - K_g - M_h - R_g)(F_h + K_h + M_h + R_h - C_h)$	$C_g - C_h + C_p - F_g + F_h - F_p - K_g + K_h - R_g + R_h$
(1, 1, 0)	$(F_p - C_p)(C_g + F_h - K_g - R_g)(C_h - F_h - K_h - M_h - R_h)$	$C_g + C_h - C_p + F_p - K_g - K_h - M_h - R_g - R_h$
(1, 1, 1)	$(C_p - F_p)(C_g - F_h + F_p - K_g - R_g)(C_h - F_h - K_h - M_h - R_h)$	$C_g + C_h + C_p - K_g + K_h - M_h - R_g - R_h$

Construction of the System Dynamics Simulation Model

According to the aforementioned analysis, we used Vensim PLE (Ventana Systems, Inc) to build a system dynamics model of the evolutionary game among the government, hospitals, and patients in the vertical integration of EHRs in the medical consortium, as shown in Figure 1. In the figure, x, y, and z are 3 stocks, representing the time integration of 3 rate variables, namely, the change rate of government promotion, the change rate of hospital participation, and the change rate of patient supervision, expressed by their respective replication dynamic equations; E_{g1}, E_{g2}, E_{h1}, E_{h2}, E_{p1}, and E_{p2} are 6 intermediate variables, which respectively represent the expected return of each entity under different strategic states. The remaining 12 parameters are external factors outside the system boundary that may affect stock changes. The arrow lines indicate the causal relationship between 2 elements. The interaction of cause and effect acts as a causal feedback loop.

The purpose of system dynamics simulation is to reveal the law of development and change of things. The model construction focuses on the consistency, adaptability, and effectiveness of its overall structure. Therefore, the design of a system dynamics model does not require the authenticity and accuracy of parameter setting [19]. In this paper, common assignment methods are used for reference in parameter setting, and finally determined according to the experience of the interviewed experts. The specific parameter settings are as follows: initial time=0 years, final time=20 years, time step=0.125 years; R_g=30; C_g=6; K_g=3; F_g=4; R_h=50; C_h=7; K_h=5; F_h=8; M_h=10; C_p=1; F_p=2; and R_p=6. It should be noted that different initial values of each parameter will not change the simulation conclusion [20].

Ethical Considerations

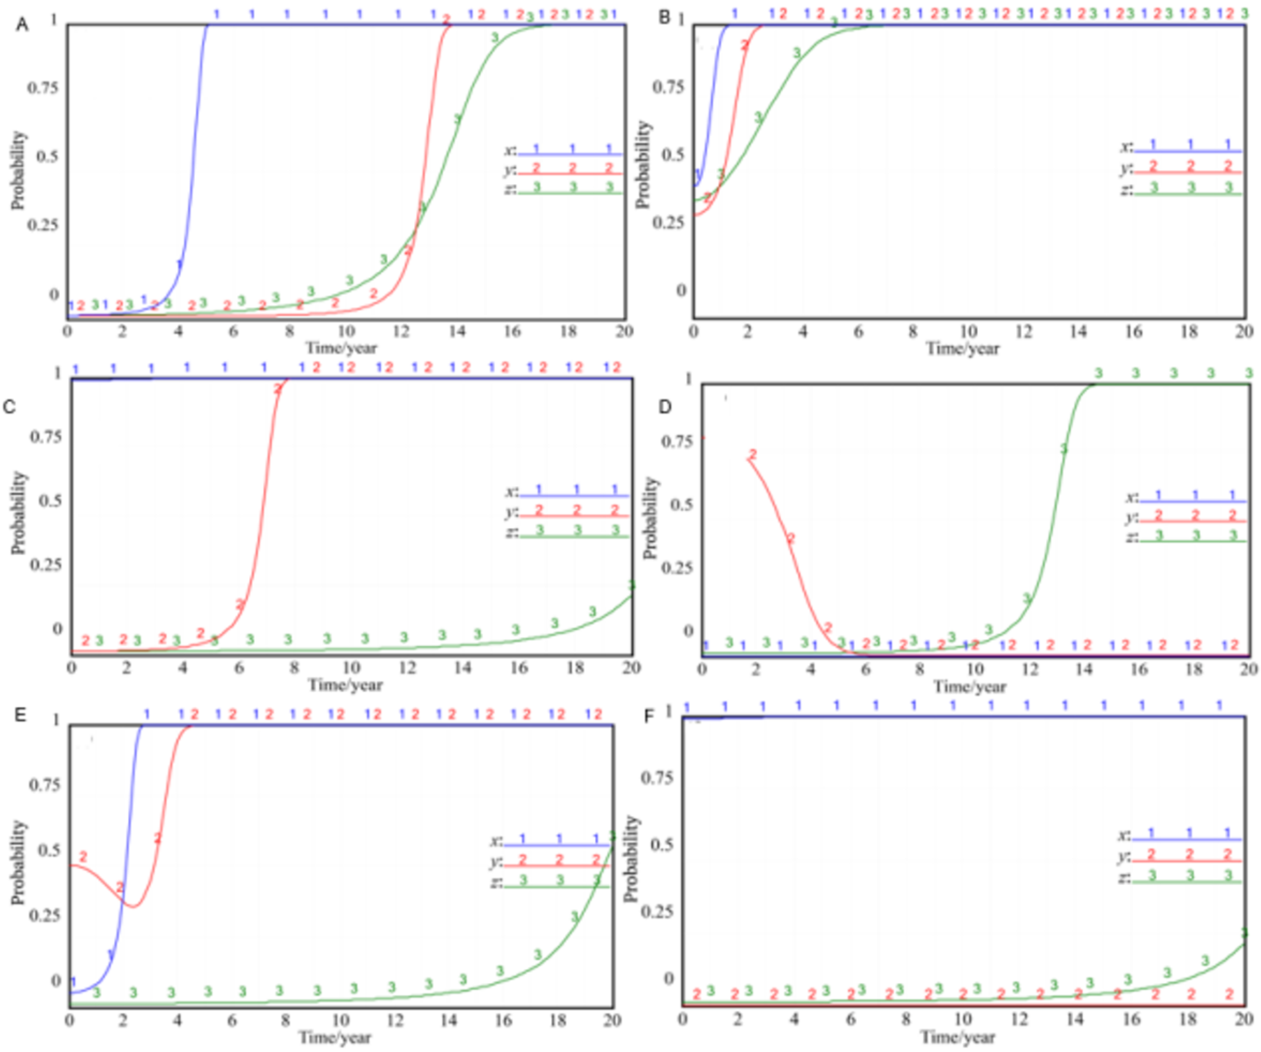
Because no specific people or animals are involved in the research and no individual privacy is involved, academic ethics review is not required.

Results

Holistic Simulation Analysis of the Evolutionary Game Model

The initial state of the government, the hospital, and the patient in the evolutionary game is pure strategy, that is, each party's strategy choice is 0 or 1, but the 8 possible equilibrium states formed by this are unstable. As long as one party's strategy is slightly adjusted, the other parties will learn to imitate and then choose strategies with higher returns, and the whole game system will evolve into a new equilibrium state. Taking the (0, 0, 0) combination strategy as an example, the evolutionary game process under different values of *x*, *y*, and *z* is shown in Figure 2 (the ordinates in the figure represent the probability of strategy selection of the government, hospitals, and patients in the corresponding state).

Figure 2. Process of the evolutionary game in the case of combined values of *x*, *y*, and *z*. (A) *x*=0.01, *y*=0.01, *z*=0.01; (B) *x*=0.45, *y*=0.35, *z*=0.4; (C) *x*=0.99, *y*=0.01, *z*=0.01; (D) *x*=0, *y*=0.8, *z*=0.01; (E) *x*=0.05, *y*=0.5, *z*=0.01; (F) *x*=0.99, *y*=0, *z*=0.01.



Comparing Figure 2A-C, we can see that as long as the government's strategy evolves in the direction of vigorous promotion, no matter how much the initial probability of active participation of hospitals and patients is, the strategy of active participation and supervision will be adopted eventually, that is, as long as X evolves from 0 to 1, the whole system will develop into a stable state of (1, 1, 1), and it shows that the evolution speed of the government's strategy is faster than that of the hospital's strategy. The evolution speed of the hospital's strategy is faster than that of the patient's strategy. At the same time, when the government's strategy changes from 0 to 0.01 or from 1 to 0.99, it will eventually evolve into the strategy of trying to promote, showing that the strategy of trying to promote is always the best strategy of the government. During the vertical integration of cross-agency EHRs in the medical consortium, the government has always been and should be in the leading position. In specific practice, the government should take the initiative to promote rather than completely transfer the responsibility to the hospital.

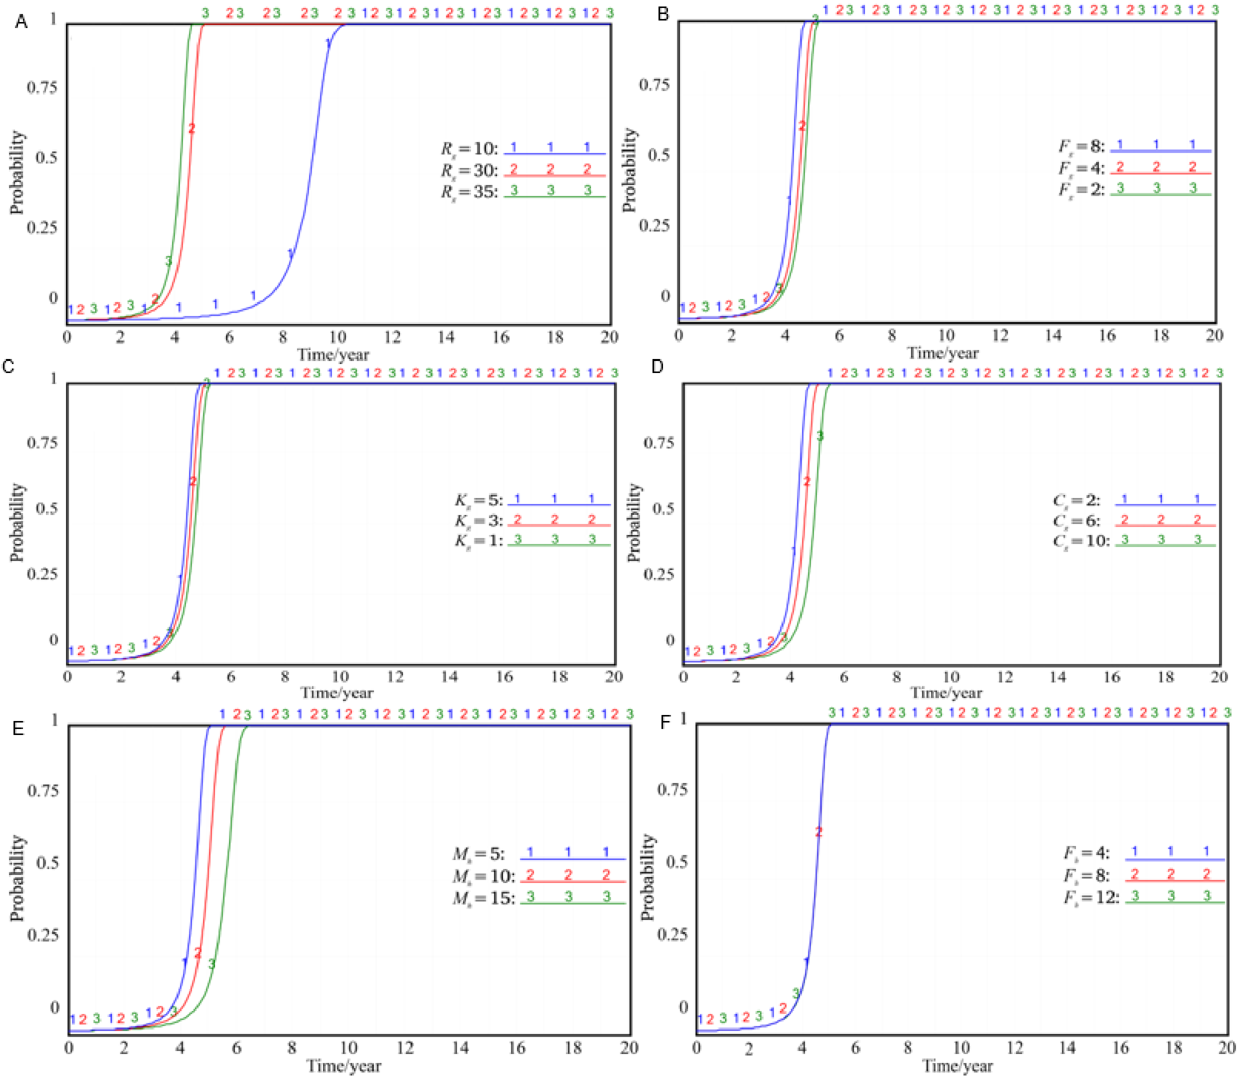
When the government chooses to promote the strategy, the hospital will always reach the status of 1 before the patients. However, comparing Figure 2D,E, it can be found that when the government chooses the negative treatment strategy, even if the hospital has high enthusiasm to participate in the vertical integration of EHRs at the beginning, it will gradually choose the negative participation strategy as time goes on; however, when the hospital completely chooses the passive participation strategy, even if the government adopts the promotion strategy again, it will be difficult to promote the hospital from the passive strategy to the active participation in a short time. The enlightenment from this conclusion is that the local government should do a good job in the overall design and development planning at the beginning, or it will be difficult to achieve the national goal of vertical integration of EHRs.

It can be seen in Figure 2 that the patients were the slowest to choose the active supervision strategy, but this is always the best strategy for patients. At the same time, it was also found that once patients choose the active supervision strategy, no matter how the strategies of the government and hospital change, the patients will tend to the active supervision strategy. Through the overall simulation analysis, it can be seen that the evolutionary game system will finally reach the equilibrium state at (1, 1, 1) after the 3 parties' strategy mutation, learning imitation, and strategy adjustment in the game process.

Factors Influencing the Government's Strategy Selection

According to the model simulation, 7 external variables such as the revenue R_g and cost C_g when the local government tries to promote, the cost K_g and punishment F_g when the local government treats the hospital negatively, the government subsidy F_h to the hospital, the supervision reward F_p to the patients, and the punishment M_h when the local government participates in the hospital negatively will affect the local government's strategy choice (Figure 3). It can be seen from Figure 3A-C that R_g, F_g, and K_g have similar effects on the government's strategy selection. In the initial value state, increasing the values of the 3 parameters will make the government's promotion probability x reach 1 earlier, which means increasing the revenue when the government is trying to promote. By contrast, increasing the cost and punishment of the government's negative treatment of the integration of EHRs will enhance the government's enthusiasm for trying to promote. Comparatively, income has a greater impact on the choice of the government's strategy. Comparing Figure 3D,E, it can be seen that C_g and M_h have similar effects on the government's strategy. Increasing the values of the 2 parameters respectively will prolong the period for the government to choose the strategy of trying to promote, which indicates that the higher the promotion cost, the lower the probability of the government trying to promote. It is worth mentioning that when the punishment M_h for passive participation in the hospital is increased to a certain extent, the government will slow down its efforts to promote the stability of the strategy, which indicates that the government cannot blindly increase its revenue by increasing the punishment. It also means that the government revenue R_g pays more attention to the social value after the integration of EHRs rather than punishing the hospital. The change of F_h and F_p has no obvious impact on the government's strategy. The curve trend after the change of the 2 parameters is basically the same, as shown in Figure 3E, which means that as long as the goal of integrating medical resources to improve medical efficiency can be achieved, the local government is likely to be willing to grant subsidies and supervise incentives. In other words, whether to give subsidies to hospitals or reward patients for supervision is not the main factor affecting the government's choice of strategies.

Figure 3. Impact of external variables on government's strategy selection. (A) The impact of R_g on the choice of government's strategy. (B) The impact of F_g on the choice of government's strategy. (C) The influence of K_g on the choice of government's strategy. (D) The influence of C_g on the choice of government's strategy; (E) The impact of M_h on the choice of government's strategy; (F) The impact of F_h on the choice of government's strategy.

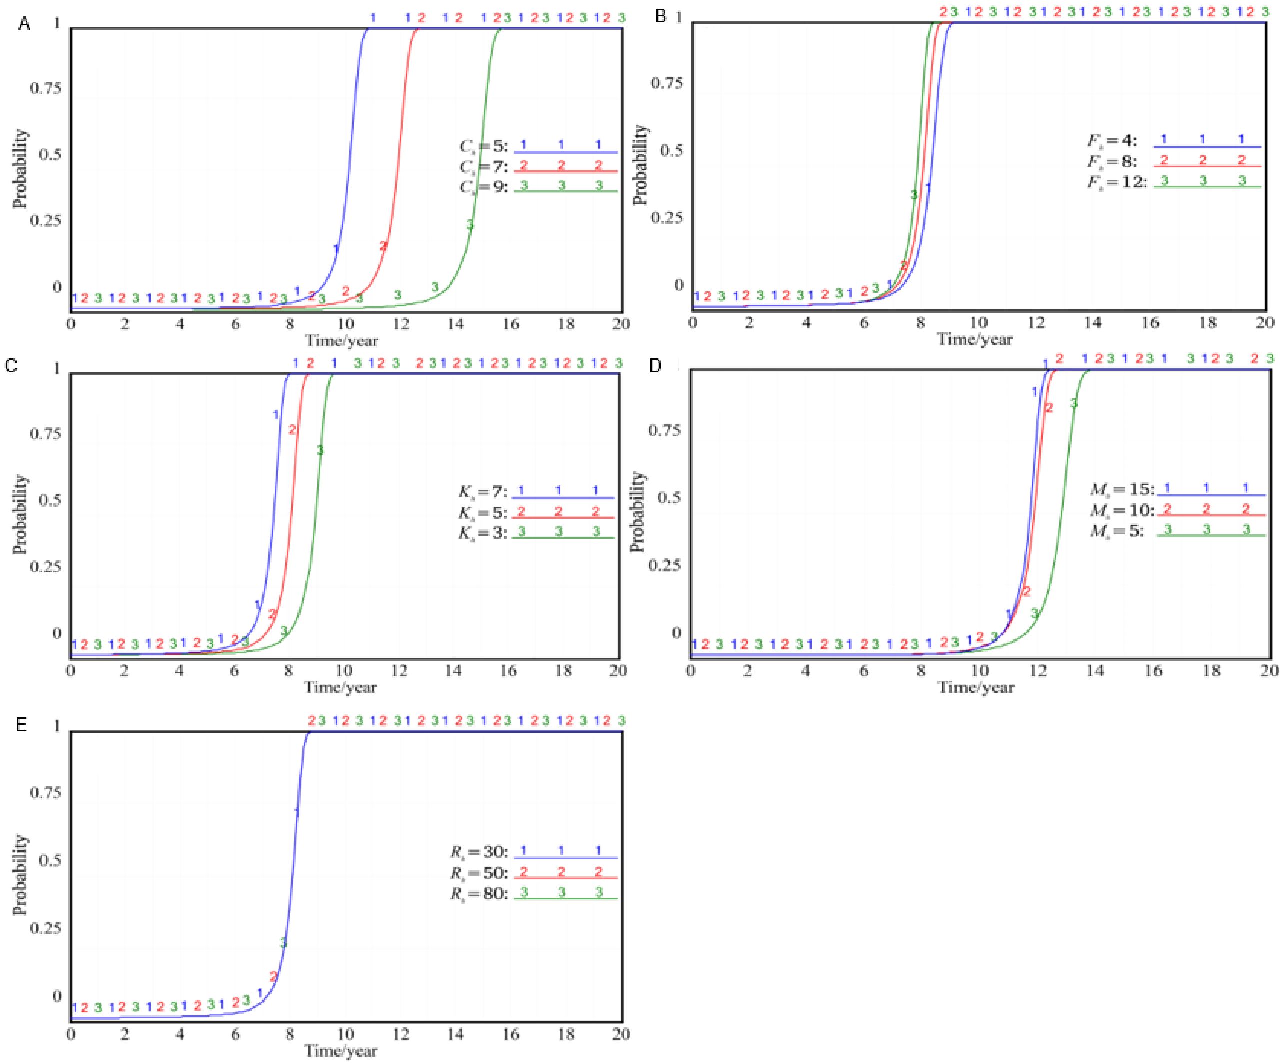


Factors Influencing the Hospital's Strategy Selection

Through simulation, it can be found that 4 external variables, namely, the cost C_h when the hospital actively participates, the cost K_h when the hospital passively participates, the government subsidy F_h when the hospital actively participates, and the punishment M_h when the hospital passively participates, will affect the choice of the enterprise strategy (Figure 4). When the value of C_h is smaller or the values of K_h, F_h, and M_h are larger, the probability of hospitals choosing the active participation strategy will be greatly increased. According to the analysis in Figure 4D, when the punishment M_h for the government's passive participation in the hospital increases to a certain extent, the marginal utility of the punishment measures will be greatly weakened, that is, when the punishment is increased to a certain extent, the incentive effect of the punishment itself will be weakened. A consistent conclusion has been reached in the analysis of the influencing factors of the government's strategy choice.

It was also found in the simulation that the hospital's revenue R_h under normal conditions will not affect its strategy choice (Figure 4E). This shows that neither large hospitals that occupy an absolute dominant position in medical information nor small hospitals with limited resources will refuse the vertical integration of EHRs because of the amount of their own information resources. In other words, both large hospitals and small hospitals have the potential willingness to act collectively to achieve the vertical integration of EHRs. This finding is of great significance for the government to vigorously promote the vertical integration of EHRs (eg, electronic medical records).

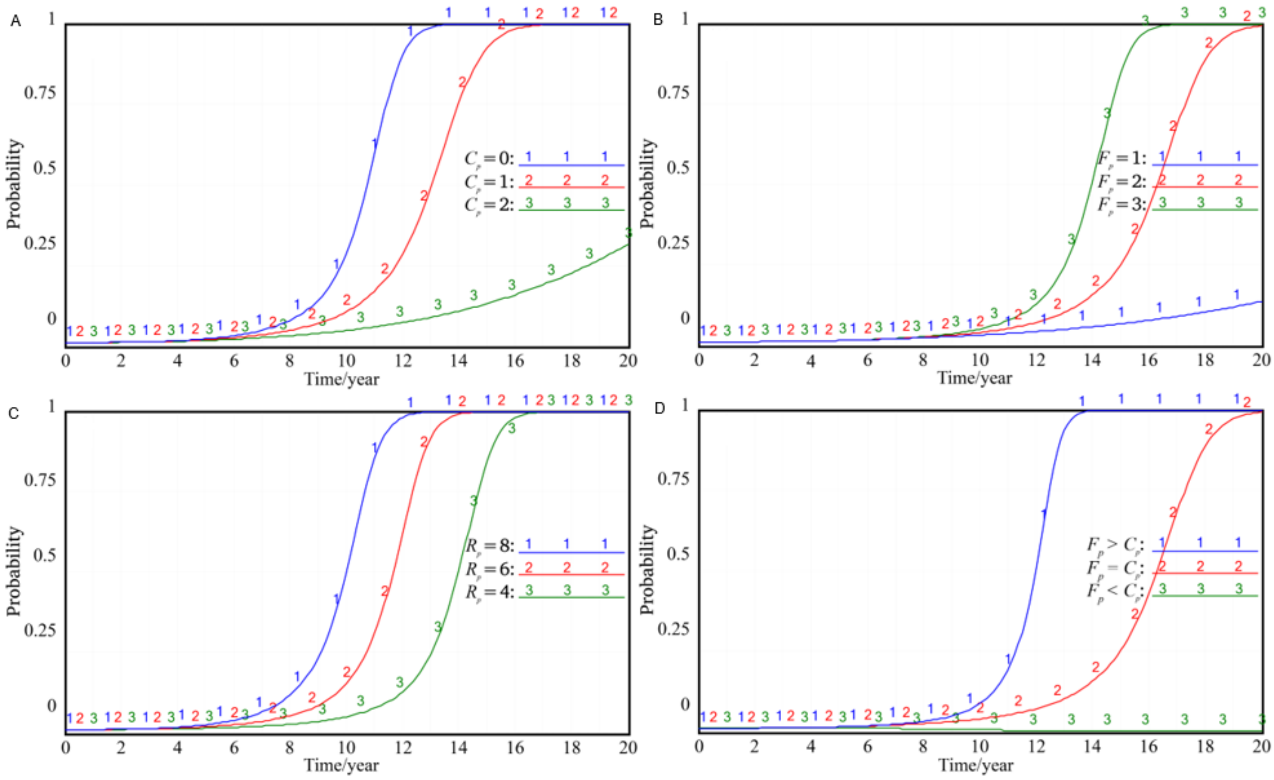
Figure 4. Impact of external variables on the hospital's strategy selection. (A) Impact of C_h on the hospital's strategy selection. (B) Impact of F_h on the hospital's strategy selection. (C) Impact of K_h on the hospital's strategy selection. (D) Impact of M_h on the hospital's strategy selection. (E) Impact of R_h on the hospital's strategy selection.



Factors Influencing the Patient's Strategy Selection

The factors that affect the patient's strategy selection mainly include the cost C_p and the reward F_p when the patient actively participates in the supervision, as well as the social damage R_p caused by the hospital's negative participation (Figure 5). We can see in Figure 5A,B that when the patient's supervision cost C_p becomes larger or the government reward F_p becomes smaller, the probability of patients choosing the active supervision strategy will obviously decrease. It can be seen from the simulation that the probability of patients choosing the active supervision strategy is determined by the difference between F_p and C_p, as shown in Figure 5C. When $F_p>C_p$, patients tend to choose active supervision. However, when $F_p=C_p$, the probability of patients choosing active supervision will significantly decrease. At this time, an increasing number of patients will take the "free riding" behavior and give up supervision, but when $F_p<C_p$, the probability of patients choosing active supervision is very low, and they will finally give up supervision. Therefore, to achieve the goal of vertical integration of EHRs, the government should provide some incentives for patient supervision and try to reduce the cost of patient supervision. When the social damage R_p caused by the hospital's negative participation is greater, the patients are more inclined to adopt the active supervision strategy, but this is not what we expect (Figure 5D). Therefore, the government is required to firmly choose and strive to promote the strategy to guide and encourage hospitals to choose the active participation strategy, so as to reduce the overall social damage.

Figure 5. Impact of external variables on the patient's strategy selection. (A) Effect of C_p on the patient's strategy selection; (B) Effect of F_p on the patient's strategy selection; (C) Joint effect of F_p and C_p on the patient's strategy. (D) Impact of R_p on the patient's strategy selection.



Discussion

Principal Findings

Using evolutionary game analysis and system dynamics simulation methods, we analyzed the evolution process of long-term strategies of the government, hospitals, and patients in the vertical integration of EHRs, and the influencing factors and mechanisms of each party's strategy choice. The principal findings are described below.

The choice of strategies of the 3 parties is jointly determined by a variety of external factors. Increasing the benefits of the government's efforts to promote and increasing the costs and penalties of the government's negative treatment have a greater impact on the government's strategic choice, while subsidies to hospitals and incentives to patients only have a little impact on the government's strategic choice. The following scenarios would motivate hospitals to choose an active participation strategy: lower cost of active participation, higher cost of passive participation, higher government subsidies, and reasonable penalties. The revenue of hospitals under normal circumstances have a little impact on the choice of hospital's strategies. Whether patients choose the active supervision strategy is mainly determined by the difference between the government reward and the supervision cost. Only when the patient supervision reward is higher than its cost can the purpose of encouraging patients to actively supervise be achieved.

The vertical integration of EHRs within the medical consortium has practical feasibility. In the model simulation, it is found that the strategies of the government, hospitals, and patients finally reach the optimal equilibrium state at (1, 1, 1), and both large and small hospitals have the potential willingness to take unified action to achieve the vertical integration of EHRs. However, this requires the government to be in a leading position and make every effort to promote it. It is difficult to achieve the goal of vertical integration of EHRs if the integration responsibility is fully delegated to the hospital.

Constructing a multiagent coordination mechanism under the guidance of the government is the only way to achieve the goal of vertical integration of EHRs in the medical consortium. The research shows that the government's strategy is influenced by strategies of both hospitals and patients. Patient's strategy is also influenced by the strategies of both the government and the hospital; the hospital's strategy choice is mostly directly affected by the government's strategy, and the patient's strategy can only indirectly affect the hospital's strategy choice through the impact on the government's strategy. Establishing a good cooperation mechanism can not only improve the cooperation efficiency, but also reduce the participation cost, so as to accelerate the realization of the integration goal. Therefore, it is necessary to build a multibody coordination mechanism led by the government and fully mobilize the enthusiasm of all parties so that the medical consortium can achieve the goal of vertical integration of EHRs.

The simulation results revealed that the appropriate increase of government subsidies for active participation and penalties for passive participation can enhance the enthusiasm of hospitals, while the improvement of supervision incentives can also encourage patients to choose active supervision strategies. Therefore, the government should establish a reasonable reward and punishment mechanism, and design a detailed implementation plan. The government should also build a reasonable benefit distribution mechanism among medical institutions to ensure the mutual use performance after the vertical integration of EHRs. Performance evaluation plays an important role in guiding, supervising, and promoting the vertical integration, and is also the main basis for establishing a reward and punishment mechanism and a benefit distribution mechanism. Therefore, the government should independently design the performance evaluation mechanism of information resource integration in the evaluation system of medical consortium construction, to reduce "free riding" opportunistic behavior and improve the enthusiasm of hospitals and patients to participate.

Limitations

Admittedly, there are limitations in this study. First, only the 3 core participants (the government, hospitals, and patients) were considered, while other stakeholders (eg, technology providers) were not considered. Second, because of the constraints of research conditions, real data available for prediction and simulation were not obtained. In the future, we will consider a wider range of stakeholders and seek to obtain real data for empirical studies to further improve the reliability of our findings.

Conclusions

We should build a multiagent coordination mechanism. As discussed in the preceding sections, strategies of the government, hospitals, and patients are intertwined and each is influenced by multiple external factors. Achieving the goal of vertical integration of EHRs requires the participation of multiple parties, with the government in a leading position. Establishing a good coordination mechanism can improve the efficiency of collaboration and reduce the cost of participation, thus accelerating the achievement of integration goals. Therefore, it is imperative to establish a government-led multiparticipant collaborative mechanism.

We should set up a reward and punishment mechanism and a benefit distribution mechanism. Simulation results show that appropriately increasing government subsidies when hospitals are actively involved and penalties when they are negatively involved can increase hospital motivation. Increasing monitoring rewards can also motivate patients to choose active monitoring strategies. Therefore, the government should establish a reasonable reward and punishment mechanism and design a detailed reward and punishment implementation plan. It should also build a reasonable benefit distribution mechanism among medical institutions to ensure the interoperability performance of vertically integrated EHRs.

We should establish a scientifically integrated performance evaluation mechanism. Performance evaluation aims to compare, measure, and judge the gap between the real development status and the predefined expectation standard. The evaluation results have an important role in guiding, supervising, and promoting the development of EHRs toward verticality, and are also the main basis for setting up reward and punishment mechanisms and benefit distribution mechanisms. Therefore, the government should independently design the performance evaluation mechanism of information resource integration in the evaluation system of medical consortium construction, so as to reduce the opportunistic behavior of "free riding" and increase the enthusiasm of hospital participation.

Acknowledgments

This work was funded by the National Natural Science Foundation of China (grant numbers 72164037 and 71864021).

Authors' Contributions

SHT contributed to model construction and simulation analysis, and wrote the original draft. YC reviewed and edited the manuscript.

Abstract

Background: The COVID-19 pandemic introduced an urgent need for effective strategies to disseminate crucial knowledge and improve people's subjective well-being. Complementing more conventional approaches to knowledge dissemination, game-based interventions were developed to create awareness and educate people about the pandemic, hoping to change their attitudes and behavior.

Objective: This study provided an overview and analysis of digital and analog game-based interventions in the context of the COVID-19 pandemic. As major pandemics and other large-scale disruptive events are expected to increase in frequency in the coming decades, this analysis aimed to inform the design, uptake, and effects of similar future interventions.

Methods: From November 2021 to April 2022, Scopus, Google, and YouTube were searched for articles and videos describing COVID-19–themed game-based interventions. Information regarding authorship, year of development or launch, country of origin, license, deployment, genre or type, target audience, player interaction, in-game goal, and intended transfer effects was extracted. Information regarding intervention effectiveness was retrieved where possible.

Results: A diverse assortment of 23 analog and 43 digital serious games was identified, approximately one-third of them (25/66, 38%) through scientific articles. Most of these games were developed by research institutions in 2020 (13/66, 20%) and originated in Europe and North America (38/66, 58%). A limited number (20/66, 30%) were tested on relatively small samples, using a diversity of research methods to assess the potential changes in participants' knowledge, attitudes, and behaviors as well as their gameplay experience. Although most of the evaluated games (11/20, 55%) effectively engaged and motivated the players, increased awareness, and improved their understanding of COVID-19–related issues, the games' success in influencing people's behavior was often unclear or limited.

Conclusions: To increase the impact of similar future interventions aimed at disseminating knowledge and influencing people's attitudes and behaviors during a large-scale crisis, some considerations are suggested. On the basis of the study results and informed by existing game theories, recommendations are made in relation to game development, deployment, and distribution; game users, design, and use; game design terminology; and effectiveness testing for serious games.

COVID-19; serious game; game-based intervention

Introduction

Background

The outbreak of the novel coronavirus causing COVID-19 was declared a pandemic in March 2020 [1]. With increasing restrictions and uncertainty, a growing number of studies have reported troubling large-scale psychological effects of the COVID-19 pandemic, including worry, fear, anxiety, boredom, frustration, irritability, anger, sadness, and depression [2-7]. On a collective level, health anxiety, collective disorientation, community panic, crisis fatigue, and social isolation fatigue have been observed [3,4,8]. These effects seem to be perpetuated by *doomsurfing* or *doomscrolling*, which refers to the tendency to continually search for bad news on the web even though it is saddening, disheartening, or depressing [9]. An increase in additional dysfunctional behaviors such as panic purchasing of essential household items, increased consumption of psychoactive substances, weight gain because of stress-induced eating, and complete social withdrawal has suggested an imbalance between increased environmental demands and the efficacy of people's resilience and coping. Experts have advised that people adhere to daily routines and maintain a strong degree of social connectedness to improve communication and reduce boredom [10-12]. Less conventional means to maintain or improve people's subjective well-being have also been investigated, including digital health interventions (ie, telemedicine, eHealth, and mobile health) [13-15], exergames [16], arts-based interventions [10], bibliotherapy [17], and the company of pet animals [18].

Playing games has been a popular coping strategy during the pandemic [19,20]; it has even been recommended by the World Health Organization (WHO) as an effective way to stop the spread of COVID-19 [21]. Kleinman et al [22] reported that people resorted to games to maintain their mental well-being (eg, to cope with loneliness, escape from the troubling real world, or replace the loss of routines because of quarantine), connect with others (eg, with distanced friends and family, people confined to the same household, or new people), or substitute reality (eg, using game characters as a substitute for real interactions and hosting internet-based events). Some people have also found solace in creating games or gamifying everyday activities to cope with distress during quarantine [22].

During the pandemic, an increased interest specifically in pandemic-themed games such as the board game *Pandemic*, which was developed after the 2003 severe acute respiratory syndrome epidemic, was observed [23]. In 2020, over 50 global game industry leaders launched the campaign *#PlayApartTogether* to encourage gamers to follow the WHO guidelines as well as incorporate COVID-19 prevention messages into their games [24,25]. Thus, in addition to *entertainment* games intended to be played primarily for amusement purposes, a considerable number of *serious* games were developed to educate people about the COVID-19 pandemic, influence their behavior, and improve their well-being in terms of increased life satisfaction and decreased negative affect. These games drew upon the proven positive effect that (serious) games can have on increasing health literacy [26,27]. Although the entertainment in playing games can in itself benefit one's psychological well-being, our study focuses on *serious* games that were intentionally designed to spread awareness and knowledge of COVID-19, promote healthy behaviors, and increase people's resilience during the pandemic.

Serious games (hereinafter referred to as *games*) often use entertainment qualities to increase player motivation to learn and change their attitudes or behavior in the real world (ie, to facilitate *transfer effects* such as contagion-preventive behavior) [28]. They can increase people's understanding of complex situations and equip them with the knowledge and skills that are required in real life [24], especially when immersive simulations of threatening new or unusual situations are used in a safe environment that players can explore to prepare for the possible consequences of a real disaster [29]. Although multiple theories on the motivational effects of game and play (starting in 1938 with *Homo Ludens* by Huzinga [30,31]) have been developed, it is very difficult to specify the exact game elements that cause games' transfer effects [32,33]. Some theorists have stated that games are ideal candidates for optimally responding to universal motivational needs (cf the relationship between games and self-determination theory [34]), whereas other theorists [35] have claimed that games provide a safe space to explore and play along the dimensions of rule-based games (*ludus*) and spontaneous play (*paidia*). In addition to the motivational effects of game elements, such as rewards, challenges, or imagination [36], games can motivate people by offering an alternative world that is fun, safe, and engaging. Huizinga [30] dubbed this (experienced) game world "the magic circle," defining it as "a temporary world within the ordinary world with specific time- and space-boundaries." Several theories, such as the theory of narrative transportation [37] and make-believe [38], describe why people tend to be attracted to these alternative worlds. Serious games make use of the motivational aspects of (entertainment) games to intentionally achieve effects in the *ordinary* or *real* world. These can involve effects on awareness (cf health risk awareness [39]), health knowledge [40], health attitudes [41], and health behaviors [42].

Objectives

Recent reports such as that by Metabiota [43] have warned that the risk of another major pandemic during our lifetimes is higher than many expect—they estimate the likelihood of another pandemic occurring within the next 25 years to be 47%-57%. Similarly, Marani et al [44] predicted up to a 3-fold increase in the yearly probability of extreme epidemics in the coming decades. This implies that the games developed in response to the recent pandemic could potentially serve as a basis for future games, indicating a need to explore the landscape of COVID-19–themed games. Apart from a recent analysis of 5 studies that evaluated 4 games in total [45], to date, no comprehensive reviews that could help evaluate the various game design decisions for this specific context have been published. Thus, the overview presented in this paper aims to inform the design of similar game-based interventions by showcasing the diversity of intentions and design strategies.

Methods

Search and Selection of COVID-19 Games

In November 2021, we performed a search of Scopus to identify scientific articles that described the development or testing of COVID-19–themed games. The search was limited to articles and conference papers published in English after 2018 that included the keyword "game*" and any of the keywords "covid*," "sars-cov*," "pandemic*," or "lockdown*" in the title. To further reduce the number of irrelevant results, we excluded those where the word *game* was used in relation to *game changer* or the Olympic and Paralympic games. The search was then repeated in April 2022 to include the most recent studies. Titles and abstracts of the identified 181 results were screened to exclude publications that did not focus on games developed to educate the general public on the COVID-19 pandemic. In total, 34 full texts describing 25 different games were included in the review.

An important consideration that informed the literature review was that games are not necessarily disseminated through or discussed in scientific publications. To avoid excluding relevant games that had only been disseminated through nonscientific media, Google and YouTube were also searched using the aforementioned keywords. This search, which was performed from November 2021 to April 2022, identified 42 additional games developed by private citizens, studios, and profit and nonprofit organizations. Owing to the overwhelming number of prototypes of digital games developed primarily for game jams (eg, International Festival of Independent Games "JAMMING THE CURVE: COVID-19 Game Jam") or competitions (eg, the 2021 Institute of Electrical and Electronics Engineers Conference on Virtual Reality and 3D User Interfaces contest "Challenging Pandemics"), these were not included in this study.

Data Extraction

The identified games were analyzed and categorized based on the Comprehensive Taxonomy for Serious Games by De Lope and Medina-Medina [46]. This taxonomy builds on a series of concepts from existing partial classification systems to collect and organize a large number of game features when developing new games or when analyzing or comparing existing ones [46]. Information regarding the games' authorship, license, deployment, genre or type, target audience, player interaction, in-game goal, and intended transfer effects was extracted. Information regarding the year of development or launch, country of origin, and user testing was also obtained where possible.

Results

COVID-19 Games

Overview

By January 2022, a total of 66 COVID-19–themed games—23 (35%) analog and 43 (65%) digital—were identified. Detailed overviews of analog and digital games are provided in Multimedia Appendix 1 [47-52] and Multimedia Appendix 2 [53-70], respectively; Figures 1-10 show 10 game examples. The general findings are presented in the following sections.

Figure 1. Clinic Deluxe Edition: CoVid_19 variant (image reproduced with permission from Alban Viard [71]).

Figure 2. Plague Inc.: The Cure (image reproduced with permission from Ndemic Creations [72]).

Figure 3. Antidote COVID-19 (image reproduced with permission from Psyon Games [73]).

Figure 4. At-Home Scavenger Hunt [47]. Materials developed by the Centers for Disease Control and Prevention (CDC). At-Home Scavenger Hunt

INSTRUCTION SHEET — To be used by facilitator

Instructions: Announce the items to be searched for one at a time. You don't need to go in order – mix it up a bit! Do not tell participants how much each item is worth. The first player/team that brings the item to you wins the points for that item – write their name under the "**Who Found it First?**" column. Engage the participants in the discussion ideas listed to promote a conversation about staying physically, emotionally and mentally healthy during COVID-19.

Topic	Item	Points	Who Found it First?	Discussion Ideas
Protection and hygiene	Hand soap	3		Handwashing is a simple yet effective way to prevent the spread of SARS-CoV-2, the virus that causes COVID-19. **Q:** When should you wash your hands? **A:** Hands should be washed often with soap and water for at least 20 seconds after you have been in a public place, or after blowing your nose, coughing, or sneezing. It's especially important to wash: • Before, during and after preparing food • Before eating food • Before touching your face • After using the restroom • After leaving a public place • After blowing your nose, coughing, or sneezing • Before putting on your cloth mask • After removing your cloth mask • After changing a diaper • After caring for someone sick • After touching animals or pets, pet foods or treats https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/prevention.html
	Hand sanitizer	1		If soap and water are not readily available, use a hand sanitizer. Cover all surfaces of your hands and rub them together until they feel dry. **Q:** What is the minimum percentage of alcohol that a hand sanitizer must have? **A:** Use a hand sanitizer that contains at least 60% alcohol. https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/prevention.html
	Cloth mask	3		**Q:** True or False – Masks are only meant to protect you. **A:** FALSE You could spread COVID-19 to others even if you do not feel sick. Masks are meant to protect other people in case you are infected. https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/prevention.html
	Box of tissues	1		**Q:** True or False – Using a tissue eliminates the need to wash your hands with soap and water after coughing or sneezing. **A:** FALSE Throw used tissues in the trash. Immediately wash your hands with soap and water for at least 20 seconds. If soap and water are not readily available, clean your hands with a hand sanitizer that contains at least 60% alcohol. https://www.cdc.gov/coronavirus/2019-ncov/prevent-getting-sick/prevention.html
Social Connectedness	Unused USPS Stamp	5		**Q:** When was the last time you wrote and sent a letter by mail? **A:** *[Different answers by participants]* During times of increased social distancing, people can still maintain social connections and care for their mental health. You can practice handwriting and grammar by writing letters to family members – it is a great way to connect and limit face-to-face contact! https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/managing-stress-anxiety.html https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/children/learning.html
	Landline phone	5		**Q:** In what creative ways have you connected with others during COVID-19? **A:** *[Different answers by participants]* Connecting with others is a healthy way to cope with stress. Different forms of contact can help you and your loved ones feel socially connected, less lonely, or isolated. https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/managing-stress-anxiety.html
Learning	Board Game	3		**Q:** What is (or was) your favorite board game? Why? **A:** *[Different answers by participants]* Learning can be fun! Hands-on activities like puzzles, painting, drawing, and making things can help children learn – even when school is out. Independent play can be used in place of structured learning. Encourage children to build a fort from sheets or practice counting by stacking items. https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/children/learning.html
	Book			**Q:** What was the last book you read for fun? What was it about? **A:** *[Different answers by participants]* Sharing books and talking with children is a way in which parents can support their child's healthy development. https://www.cdc.gov/ncbddd/childdevelopment/facts.html
Physical Activity	Baseball	4		**Q:** How can children and youth stay safe while playing team sports? **A:** It is possible to keep young athletes safe: • Reduce physical closeness between players when possible • Minimize sharing of equipment or gear • Limit travel outside of your area • Identify small groups and keep them together • Practice social distancing and use cloth masks, when appropriate https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/youth-sports.htm
	Tennis shoes or sneakers	2		**Q:** What are your plans to be physically active tomorrow? **A:** *[Different answers by participants]* Play outdoors – it's great for physical and mental health. Take a walk with your family or go on a bike ride. Use indoor activity breaks (like stretch breaks or dance breaks) throughout the day to stay healthy and focused. https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/children.html
Nutrition	Drinking water	2		**Q:** Can you get COVID-19 from drinking water? **A:** There is no evidence showing anyone has gotten COVID-19 through drinking tap or bottled water, or from recreational water, or wastewater. The risk of COVID-19 transmission through water is expected to be low. Getting enough water every day is important for your health. Carry a water bottle for easy access. Choose water instead of sugar-sweetened beverages. Generally, you will save money, reduce calories, and support your health and teeth. https://www.cdc.gov/healthywater/drinking/nutrition/index.html https://www.cdc.gov/oralhealth/basics/childrens-oral-health/index.html
	Apple	4		**Q:** True or False – Taking care of your body, including good nutrition, is important during COVID-19. **A:** TRUE To help cope with stress that may be related to the pandemic, take care of your body, including by eating nutritious food, as part of self-care. Getting the right amount of nutritious food like plenty of fruits and vegetables, lean protein, and whole grains, and staying hydrated is important for health. https://www.cdc.gov/coronavirus/2019-ncov/daily-life-coping/food-and-COVID-19.html

Release Year and Location

The vast majority of the identified games were developed or launched in 2020 (41/66, 62%); the rest were developed or launched in 2021. The largest number of games originated in the United States (10/66, 15%), India (9/66, 14%), and the United Kingdom (7/66, 11%). The countries of origin of other games included Denmark, the Netherlands, and Switzerland (3/66, 5% of the games each); Canada, Czech Republic, Finland, Germany, Morocco, Portugal, and South Africa (2/66, 3% of the games each); and Australia, Bangladesh, Belgium, Brazil, China, France, Hungary, Indonesia, Poland, Saudi Arabia, Singapore, and Taiwan (1/66, 2% of the games each). For 8% (5/66) of the games, the country of origin could not be determined.

Authorship

The lead developers were research institutions (31/66, 47% of the games), game development studios (17/66, 26% of the games), or private individuals (13/66, 20% of the games). A total of 9% (6/66) of the games were developed by children aged 10 to 17 years (*Better than Hugo, Corona – Mit Eifer ins Geschäft, Corona Yuga, COVID-19: A Race to the Vaccine, Go Corona Go,* and *Infected!*). Governmental and nongovernmental organizations (eg, ministries, educational institutes, the WHO, the Centers for Disease Control and Prevention [CDC], the United Nations Children's Fund, and Médecins Sans Frontières) were involved in the development of 22% (5/23) of the analog games and 16% (7/43) of the digital games.

License

In total, 65% (15/23) of the analog games were commercial (price: US $6.54-33.77), 30% (7/23) were available for free (6/7, 86% of these as *Print & Play* games), and 9% (2/23) were Kickstarter prototypes. In contrast, the vast majority of digital games were free to play (20/43, 47%) or prototypes (20/43, 47%); 5% (2/43) were commercial (price: US $4.36-9.80), and 2% (1/43) were developed for internal use at a company.

Target Audience

Most games (38/66, 58%) targeted younger audiences, including children as young as 3 years old, teenagers, and university students. Analog games were often designed to be engaging for the entire family, whereas 36% (24/66) of all digital games did not have a defined target audience. Certain other games targeted very specific user groups, such as gamers, active social media users, health care workers, health enthusiasts, employees of certain enterprises, and the African population.

Game Types and Genres

Practically all games identified were simulations of the COVID-19 pandemic. Some were set in the players' immediate environment, such as the classroom (eg, *Fighting COVID-19 at Purdue University*), the office (eg, *Social Distancing – The Game*), or the supermarket (eg, *Dino-Store*), or more broadly in a village, town, or city (eg, *Clinic Deluxe Edition: CoVid_19 variant* [Figure 1], *COVID Dodge, SurviveCovid-19,* and *VRS Fight Club*); a country (eg, *Better than Hugo* and *Korona hra*); or the world (eg, *Plague Inc.: The Cure*; Figure 2), where the players were tasked with controlling the spread of the disease. Others were set in a microscopic environment of the human body, where the players assumed the role of immune cells in fighting off the infection (eg, *Antidote COVID-19* [Figure 3] and *Infekcja*) or of the virus in spreading the disease (eg, *Viruscape*). Other interesting approaches were used in games such as *At-Home Scavenger Hunt* by the CDC (Figure 4), which required the players to find relevant physical items in their actual environment; the location-based game *MeetDurian*, where virtual items could be collected in the player's physical environment (similar to *Pokémon GO*) if the player was wearing a face mask, the presence of which was detected by face recognition software; and *GO VIRAL!* (Figure 5), which was set in the environment of a simulated social media platform.

The vast majority of analog games were board games (15/23, 65%) or card games (6/23, 26%). The most common analog game types or genres were strategy games (11/23, 48%; eg, *Lockdown!*; Figure 7) and race-to-the-end games (6/23, 26%; eg, *You Make Me Sick!*; Figure 6), whereas most digital games were primarily strategy (15/43, 35%; eg, *Plague Inc.: The Cure*), action (14/43, 33%; eg, *COVID Dodge*), and trivia (12/43, 28%; eg, *Corona Bee*; Figure 8) games. Some less common game types such as meditation or Zen (*CovidShield*), hidden object (*Help to stop the COVID-19 coronavirus* and *At-Home Scavenger Hunt* by the CDC), memory (*Heroes of Covid-19*; Figure 9), and escape room–type puzzles (*COVID-19 [CORONA VIRUS]* and *Destroy COVID*; Figure 10) were also identified.

Deployment

Most digital games (23/43, 53%) were web-based and playable on PCs, mobile devices, consoles, or a combination of these. An additional 21% (9/43) were deployed for mobile platforms, 7% (3/43) were deployed for desktop and mobile platforms, 2% (1/43) were deployed for desktop only, 2% (1/43) were deployed for desktop and consoles, and 2% (1/43) were deployed for consoles only. Analog games mainly took the form of physical objects (eg, game boards with figures and dice, play money or tokens, playing cards, and puzzle pieces) or free electronic files that were designed to be printed at home (*Print & Play*).

Player Interaction

Of the 43 digital games, 37 (86%) were single-player, 4 (9%) were multiplayer (up to 7 players), and 2 (5%) were single- and multiplayer. Of the 6 multiplayer digital games, 5 (83%) were co-operative, and 1 (17%) was competitive. In contrast, all analog games (23/23, 100%) were multiplayer (up to 100 players), although single-player versions were also available in 26% (6/23) of the cases. Of these 23 games, 18 (78%) were competitive, 4 (17%) were co-operative, and 1 (4%) involved only teams or partnerships.

Gameplay Duration

Information retrieved from 15 analog games showed that gameplay duration ranged from 5 to 180 minutes—3 (20%) games required up to 15 minutes, 5 (33%) games required up to 30 minutes, 2 (13%) games required up to 45 minutes, 2 (13%) games required up to 60 minutes, and 3 (20%) games required >1 hour. The estimated duration could only be retrieved for 7% (3/43) of the digital games, which were substantially shorter than most analog games and lasted 5 to 15 minutes.

Intended Transfer Effects

Overview

In addition to a mostly entertaining *in-game goal*, serious games explicitly add a more *serious, out-game goal* [75], which refers to the intended effect of the game in the *real world* [28]; such an effect can be observed after playing the game and may include increased knowledge and awareness, skill development, and changes in attitudes or behaviors. Such serious games aim for impact that is typically long-term, in contrast to more short-term or direct forms of impact such as interactions, actions, and experiences while playing the game (for discussion on human impact–centered design, refer to the study by Fokkinga et al [77]). This repertoire of COVID-19 games covers this diversity of purposes, as summarized in Table 1 (extracted from the games' descriptions; for details, refer to Multimedia Appendix 3).

Table 1. Intended transfer effects of COVID-19–themed games (listed according to the hierarchy of effects model originally developed for advertising and recommended by McGuire [78] for use in public health campaigns [79]; N=66).

Intended transfer effect	Games, n (%)	Examples
Awareness-oriented effects	11 (17)	
Need for vaccination Preventive measures Need for well-being		• Antidote COVID-19 • Beat Corona • Corona – Mit Eifer ins Geschäft • COVID Challenge • Heroes of Covid-19 • Social Distancing – The Game
Education-oriented effects	38 (58)	
Virus Policy Vocabulary Personal care Information assessment		• Antidote COVID-19 • Clinic Deluxe Edition: CoVid_19 variant • Corona Bee • COVID Safety Simulation: CAMPUS LIFE • Govid • You Make Me Sick!
Attitude-oriented effects	12 (18)	
Improving empathy Sense of collective responsibility Critical reflection		• Better than Hugo • Breaking the Magic Circle • Corona Game • Essential Workers • GO VIRAL! • SurviveCovid-19++
Behavior-oriented effects	8 (12)	
Executing preventive measures Social conversation Staying healthy Entertainment Maintaining well-being		• At-Home Scavenger Hunt • Corona Yuga • CovidShield Game Suite • Fighting COVID-19 at Purdue University • MeetDurian • The Magic Soldier of the Human Body

Increasing Awareness and Spreading Knowledge

Overall, the games reviewed in this study aim to educate the players on the COVID-19 pandemic in an entertaining way. Practically all games (66/66, 100%) were developed to spread general awareness about COVID-19 (eg, *Is COVID-19 caused by bacteria or a virus?*; *Name one symptom of COVID-19 that affects the respiratory system*; and *What does the "19" in COVID-19 stand for?*). Some (6/66, 9%) were intended to educate people about the means and mechanisms of virus spread, the immune response, or both (eg, *True or False: COVID-19 can only be spread from person-to-person* and *Can you get COVID-19 from drinking water?*), whereas others (34/66, 52%) focus more on safety precautions to avoid catching and spreading the infection (eg, *True or False: Wearing a face mask can help stop the spread of COVID-19 to others*; *When should you wash your hands?*; and *What is the minimum percentage of alcohol that a hand sanitizer must have?*). Still others (5/66, 8%) specifically address vaccination (eg, *True or False: The COVID-19 vaccines can give you COVID-19*; *True or False: The vaccine will damage my DNA*; *I'm healthy and I'm never ill, should I still get vaccinated?*; and *Should a pregnant woman have the vaccine?*).

Influencing Attitudes

Several games (11/66, 17%) aim to cultivate people's sense of empathy and collective responsibility (eg, *Clinic Deluxe Edition: CoVid_19 variant*, *Fighting COVID-19 at Purdue University*, and *Essential Workers*) as well as encourage critical reflection on policy makers' dilemmas (eg, *Better than Hugo* and

Lockdown!) or the spread of misinformation (eg, *CoronaChampion* and *GO VIRAL!*). *Heroes of Covid-19* may be the only game to focus on positive aspects of the pandemic, raising awareness of people's noble deeds during this period (eg, "Quinn Callandar, a boy scout from Canada, used his 3D printing skills to create ear guards for people who feel pain from wearing masks all day"; "Intensive care nurse Molly Watts created a book entitled 'Dave the Dog is worried about coronavirus' to help tackle anxiety in children amid the Covid-19 outbreak"; and "Annemarie Plas from Brixton, London united the nation and gave the NHS frontline a boost with her 'Clap for our Carers' initiative.").

Influencing Behavior

Some games were designed to promote adherence to safety precautions in real-life settings. For example, *Fighting COVID-19 at Purdue University* aims to encourage students to clean their university laboratories, and *MeetDurian* encourages players to wear protective masks in public. Other games aim to stimulate behavior that can directly improve the players' well-being, such as mindfulness breathing (*CovidShield Game Suite*) and immunity-increasing nutrition (*The Magic Soldier of the Human Body*).

In most cases, the players were to adopt the positive role of a *hero* fighting the virus or protecting their avatar from infection in a simulated environment. An interesting yet less common alternative was to teach people about undesirable or unsafe behaviors by putting them in the negative role of, for example, the virus (*Viruscape*), an infected customer at a store (*Instructional remote multiplayer VR game*), or a misinformation spreader (*GO VIRAL!*).

Testing of Effectiveness in Promoting Transfer Effects

A relatively small number of scientific studies that investigated the effectiveness of the individual COVID-19–themed games (20) have been published (Multimedia Appendix 4 [80-101]). In total, 3 categories of effects were most frequently tested: the change in participants' knowledge of COVID-19 and infection prevention measures, their gameplay experience, and the games' potential to facilitate players' attitude or behavior change. The studies used various research methods and tools, including heuristic evaluations by experts, surveys composed of custom or standardized questionnaires and administered before or after gameplay, observations during gameplay, semistructured interviews, self-reports, or game log analysis after gameplay. A total of 15% (3/20) of the studies assessed the players' changes in knowledge [80-82] and attitudes [80,83,84] by comparing their pre- and postgameplay responses. One study involved a control group that watched an educational video about COVID-19 for comparison with a test group that played the game [80], whereas another used comparative analysis with other similar games [85]. With the exception of 30% (6/20) of the studies, which involved larger numbers of participants or instances of gameplay, testing was performed on relatively small samples (2-30 participants).

At this point, it is important to emphasize the diversity of methods used to assess the effectiveness of the games as these can greatly limit the comparability of the results. Nevertheless, most of the studies considered (11/20, 55%) found that the games succeeded in engaging and motivating the players [80,81,83,84,87,91,94,99,101], increasing awareness, and facilitating teaching COVID-19 hygienic knowledge [80-83,89,91]. Improved understanding led to positive changes in players' attitudes toward COVID-19 preventive measures [80,82,83,87,89,91,94,97,102]. A study reported that health anxiety remained relatively unchanged in response to playing 1 game [80].

Certain limitations of these studies have been acknowledged, especially in relation to the games' capacity to change players' behaviors. A proper assessment of the games' capacity to influence behavior was found to be particularly challenging as different sources of information may have contributed to people's adherence to safety measures [90,103] and as other factors—most notably, the players' ages—also affected the games' effectiveness [87,94]. The effectiveness of the reviewed games was often unclear or limited [98,103], and Suppan et al [92] explicitly stated that a longitudinal trial would be necessary to accurately assess their behavioral impact.

In addition, the studies recruited participants to play the games and evaluate their impact as opposed to surveying people who had already obtained and played the games through their own initiative. Information regarding the number of times the games were downloaded or played also does not appear to be structurally documented or made available; thus, it remains unclear to what extent the games were able to motivate people to play them in the first place. However, this information is of key importance as a game cannot be effective if it is not played.

Discussion

Principal Findings

This study aimed to provide an overview of games that were developed during the COVID-19 pandemic to disseminate crucial knowledge and enhance people's subjective well-being. In general, we observed an extensive proliferation of games—especially digital games—in 2020, when the pandemic was declared. Most (31/66, 47%) were developed by research institutions in Europe and North America—some in collaboration with health authorities. All efforts notwithstanding, the overall frequency of use and impact of these games seem to have been modest at most.

To effectively influence people's attitudes and behavior, design interventions need to be tailored to each situation, considering the environmental demands—as perceived by the target group—and their personal resources to meet these demands. On the basis of the findings of this study, we provide recommendations for the design of games aimed at improving people's well-being in future global health crises similar to the COVID-19 pandemic.

Game Development, Deployment, and Distribution

Overview

A game only has an impact if it is played. It is noteworthy that we only became aware of the multitude of COVID-19–themed games when we started actively searching for them. Although our experience is anecdotal, it does suggest the importance of investing time and effort in the dissemination of serious games.

Develop a Dissemination Plan

In the context of a pandemic, game developers should carefully consider their target audience. In many cases, this is probably the broadest audience possible, making it crucial to plan for the effective dissemination of the game. Most of the reviewed analog games (15/23, 65%) were commercially available physical objects, whereas most digital games (20/43, 47%) were freely accessible web-based applications. Each of the various forms of dissemination has advantages and disadvantages, but deployment strategy and cost may influence game accessibility to the greatest extent. Commercial games, for example, have an advantage in that they have access to professional dissemination channels and are often designed to be intriguing and esthetically appealing to attract people's attention. However, the cost and effort necessary to obtain such games can preclude them from reaching a broader audience. For analog games, *Print & Play* games tend to be the most convenient to access, especially when freely available on the web. Such games have a relatively low threshold for access in that buying them is not necessary.

When social distancing is required, as was the case during the pandemic, playing analog games is typically only possible for members of the same household. In contrast, digital games are easy to obtain and play remotely provided that the users have access to electricity and the internet. To maximize reach, Hill et al [82] advised that COVID-19–themed games must be platform-independent and playable with minimal hardware.

Collaborating with health authorities, the media, nongovernmental organizations, educational institutions, (local) governments, and social media influencers can also help spread awareness of a game's existence, although this may not always be the case. The designers of *Escape COVID-19*, for example, conducted a retrospective analysis to investigate the reasons for their limited success in recruiting participants for their study [104]. Specifically, they aimed to assess the effect of 3 different dissemination strategies on game account creation over a period of 6 months. In the first period (53 days), the game was disseminated by a part-time worker; following this was a press release (15 days); and in the final stage, the game was officially announced by the Swiss Federal Office of Public Health (15 days). Their findings suggested that the press release was the most successful and the official communication was the least successful. Nonetheless, the sequence and duration of communication interventions should also be considered.

Ensure the Reliability of Information

For games that aim to inform and share recommendations during a pandemic, a prominent challenge is that such recommendations are inherently dynamic. Although some information might be fixed (eg, what a virus is), other information may likely change after a game is introduced. The use of reliable sources such as the WHO, the CDC, and local governments can assure people that the communicated knowledge is factual. Practically all the reviewed games based their learning objectives on such sources. However, as guidelines may differ among different institutions and game developers may have different opinions on which information is correct, it is recommended that players be explicitly informed about the sources of the communicated knowledge. In addition, the credibility of the aforementioned sources can be subject to change, as seen with the rapidly waning trust in the CDC in the United States.

Real-time updates can be especially helpful in tackling confusion when guidelines change rapidly owing to the evolving understanding of health crises. It is critical that pandemic games be designed in a way that prevents them from becoming outdated too quickly; this can be addressed by incorporating sufficient flexibility in game design to allow for changing guidelines or information. Although this tends to be more challenging for analog games, it is possible—the content of analog games can be updated via expansion packs, and hybrid games where physical game elements are complemented by a regularly updated mobile app can be developed.

Game Users, Design, and Use

How, where, when, and with whom a game is intended to be played can influence players' motivation and the efficiency of the learning process [105]. Thus, it is important to design pandemic games that facilitate the acquisition and transfer of the intended learning objectives under pandemic-specific learning conditions.

Consider the Target Audience and Context of Use

Overview

When designing any serious game, it is generally advised to consider the entire ecosystem of stakeholders, including not only the players but also the initiators of games (eg, governments, nongovernmental institutions, health authorities, schools, and private citizens), design agencies, and game developers. The involvement of these stakeholders in various phases of game design (ie, problem definition, product design, and tailoring) can improve a game's implementation [106]. For pandemic games, this can be challenging, especially if the game is intended to appeal to a broad variety of affected people. Therefore, it is necessary to determine exactly which stakeholders need to be targeted. The following sections focus specifically on player characteristics.

Player Demographics

According to the effectiveness studies we reviewed, certain target group characteristics—most notably, age—influence people's engagement and the perceived effectiveness of the games [87,94]. Thus, caution is required when designing multiplayer games for people of different generations (eg, family games); it is important to avoid making such games too complex for very young or inexperienced audiences or too simple to effectively motivate adults and experienced players.

A general recommendation for game design is that game instructions should be easy to understand for a targeted user group. This recommendation is especially important for pandemic-focused games to minimize as much as possible the chances of spreading misinformation or confusion. Special attention needs to be paid to the language (preferably native language or multilingual versions) and vocabulary (preferably simple and familiar expressions) in the games. Using rules or elements from popular existing games (eg, *Monopoly*, *Ludo*, *Uno*, and *Pacman*) can help users understand and adopt a game more rapidly as people can only appreciate novelty when the product is also simultaneously perceived as familiar or typical [77,107].

Player Type

The process of meaning attribution can be influenced by the players' culture, personality traits, and current mental state, as well as by other people [77]. Similarly, product emotions, which are the emotions users experience in response to (playing) the game, are influenced by their personal needs, goals, values, and abilities [77]. Thus, a detailed psychological understanding of a game's target population can increase its impact.

First, it is important to understand that different people choose to play games for different reasons. A popular typology of player personalities developed by Bartle [108] distinguishes between 4 player types that differ based on their preferred way of engaging in the virtual world: *achievers*, *explorers*, *socializers*, and *killers* (for details, refer to the study by Bartle [108]). People assume different styles of play depending on their mood or in-game goals [108], suggesting that setting appropriate goals and using game elements to influence players' moods may discourage adverse social in-game behavior. However, Bartle based his taxonomy specifically on multiuser dungeon games; thus, his taxonomy cannot be directly extrapolated to other game types. The player profiles by Bartle [108] might work for entertainment games but not for serious games. To address this issue, Siriaraya et al [28] advised that users' experiential preferences be investigated for the game world as well as for the real world.

For COVID-19 games, it is also important to consider the differences between *social* and *solitary* players, especially in the degree of autonomy, presence, and relatedness they seek to experience (for details, refer to the study by Vella et al [109]). Understanding the specific needs and sources of motivation for different players can support the preferred player interaction.

Support Player Interaction

All the analog games reviewed in this study (23/23, 100%) were multiplayer and mainly competitive, whereas only 14% (6/43) of the digital games supported a multiplayer mode, of which 83% (5/6) were co-operative. The main advantage of single-player games is that they can be played at any time independently of other people. However, most single-player games do not allow for socializing, sharing opinions, or discussing ideas. In contrast, multiplayer games allow for socializing, but the minimum number of players required can limit the number of opportunities to play the game as this may depend on other people's interest, availability, or both. Optimally, a game should be designed to support both single- and multiplayer modes, as was the case for 26% (6/23) of the analog games and 5% (2/43) of the digital games studied in this review.

During the COVID-19 pandemic, collective action and compliance with safety guidelines were paramount in reducing the spread of the virus. Co-operative games can communicate this need to the players and support social bonding and collective decision-making that can be transferred from the in-game world to real-life situations. Previous studies have suggested that participation in co-operative—as opposed to competitive—multiplayer games can support team building [110-113] and increase real-world collaboration and prosocial behaviors among players [114-117]. In contrast, the motivation to win in competitive games may leave little room for bonding and the exchange of ideas, possibly limiting the encouragement of prosocial behavior. Nevertheless, competitive games tend to be more stimulating, whereas co-operative games may support passive participation when responsibilities are not equally distributed among the players. Therefore, it is advised to design for teams or partnerships, which combines both co-operation among team members and competition against the opposing team or teams.

Balance Visual Design and the Realism of the Simulated Domain

Immersive simulations of realistic environments and experiences where acquired knowledge can be put to use without the serious consequences of a real disaster may facilitate players' transfer of new knowledge to everyday life [29]; this is particularly important during pandemics, when rapid changes in attitudes and behavior are required. Presumably for this very reason, practically all the reviewed games were either literal or metaphorical simulations of the COVID-19 pandemic. However, as such games tend to emphasize educational goals, caution is necessary to adequately balance such education with entertainment so that games remain appealing to a broader audience.

To foster players' motivation and consolidate their engagement, fun elements that are unrelated to the simulated domain (eg, avatar shape or a game within a game) can be used. For example, the authors of *Escape COVID-19* found that attractive graphics that were adapted to fit the preferences of the target population were essential in increasing players' engagement [92]. Nevertheless, the designers of *Point of Contact* [82] stressed that a game's graphics and cross-player communication need to be lightweight to minimize players' dependence on high-performance devices and high-speed networks. Similarly, it is important to avoid substantial hardware demands, which were present in 2 game prototypes that were included in this study: the *Instructional remote multi-player VR game* requires access to a VR headset, and participants need to own an Xbox 360 device for the *Physical Fitness Training Program.*

Consider Time Requirements

Most of the analog games reviewed in this study (9/15, 60%) were designed for longer durations of gameplay (up to 3 hours); we could only retrieve the predicted duration for 7% (3/43) of the digital games, but the time required to play these games was considerably shorter (up to 15 minutes). The main advantage of short game durations (a few minutes) is that they do not require high levels of commitment, so the games can be played without previous planning. However, they may fail to elicit a *flow* state, reflection, or both. In contrast, long game durations (several hours) may deter potential users, especially if the game is multiplayer and requires scheduling a time that is appropriate for all players. Moreover, players may lose interest if a game lasts too long. Therefore, it is important to carefully design pandemic-themed games for optimal duration, depending heavily on the target group, game type, and intended transfer effects.

Challenge and Progression

To avoid cognitive overload, it is generally advised that games provide a clear distinction between the *active* and *reflective* phases of gameplay. Marne et al [105] suggested that intensive action phases that engage players emotionally and shift their focus toward a game's goal can be used for practice and training, whereas less intensive phases should be provided for reflection and relief purposes. During reflective phases, games should provide feedback to players so that they can understand the consequences of their actions and keep track of their own progress. However, this information must be provided in a way that does not interfere with the player's state of flow as this could cause them to lose interest in the game.

A possible solution proposed by Marne et al [105] is that individual items of obtainable knowledge or skills are represented as collectible virtual objects (*rewards*) that can be showcased or used as an asset later in the game. In addition to *material* rewards or achieving (publicly displayed) high scores, sensory stimulation (eg, sounds or graphics indicating an achievement) can also be rewarding, as can be messages of affirmation or commendation. For example, games such as *Escape COVID-19* included a positive message at the end of each level to strengthen players' motivation to comply with guidelines [92]. In such cases, simple, commonly used terminology can help a game more effectively reach broader target audiences.

Terminology for and Testing of Serious Games

In addition to the aforementioned considerations, our investigation revealed a need to agree upon a shared terminology and standardized testing approaches to improve the discourse on serious game development. From a scientific point of view, the wide diversity of findings at present renders it practically impossible to make any definitive conclusions or generalizations. A commonly agreed-upon method for effectiveness testing could facilitate the comparison of different approaches in game design and encourage the development of more impactful games. Consequently, we propose that a shared database of knowledge be created, such as the recently developed co.LAB methodological framework, which was implemented in a collaborative web platform that allows for the co-designing, codevelopment, and coevaluation of serious games [118].

Limitations

Despite all the efforts to provide a comprehensive review of COVID-19–themed games, we acknowledge that other games that were not included in this report exist (eg, competition and game jam entries were excluded). Furthermore, information on games that were not described in scientific papers was obtained from various web-based sources, potentially limiting the study's reliability. Nevertheless, we believe that this study correctly reflects the diversity of COVID-19–themed games.

Conclusions

This study aimed to provide a structured overview of serious games developed in the context of the COVID-19 pandemic to improve people's well-being through entertainment and education. We identified 66 diverse games, most of which were digital (43/66, 65%), were developed by research institutions in 2020 (13/66, 20%), and originated in Europe and North America (38/66, 58%). An analysis of the games' characteristics was performed to identify potential pandemic-specific challenges and opportunities for improvement, and some recommendations were made based on the findings of the reviewed studies and existing game theories.

In total, 2 additional themes emerged as a result of this overview. First, better planning for effective dissemination of the games appears to be necessary if the goal of these games is to reach the broadest audience possible. Second, to increase the impact of similar future interventions, the collective effort of game developers and researchers is needed to advance the discourse on game design and testing.

Abstract

Background: The success rate of tuberculosis (TB) treatment in Malaysia remains below the recommended World Health Organization target of 90% despite the implementation of directly observed therapy, short-course, a physical drug monitoring system, since 1994. With increasing numbers of patients with TB in Malaysia defaulting on treatment, exploring another method to improve TB treatment adherence is vital. The use of gamification and real-time elements via video-observed therapies in mobile apps is one such method expected to induce motivation toward TB treatment adherence.

Objective: This study aimed to document the process of designing, developing, and validating the gamification, motivation, and real-time elements in the Gamified Real-time Video Observed Therapies (GRVOTS) mobile app.

Methods: The modified nominal group technique via a panel of 11 experts was used to validate the presence of the gamification and motivation elements inside the app, which were assessed based on the percentage of agreement among the experts.

Results: The GRVOTS mobile app, which can be used by patients, supervisors, and administrators, was successfully developed. For validation purposes, the gamification and motivation features of the app were validated as they achieved a total mean percentage of agreement of 97.95% (SD 2.51%), which was significantly higher than the minimum agreement score of 70% (P<.001). Further, each component of gamification, motivation, and technology was also rated at 70% or more. Among the gamification elements, fun received the lowest scores, possibly because the nature of serious games does not prioritize the fun element and because the perception of fun varies by personality. The least popular element in motivation was relatedness, as stigma and discrimination hinder interaction features, such as leaderboards and chats, in the mobile app.

Conclusions: It has been validated that the GRVOTS mobile app contains gamification and motivation elements, which are intended to encourage medication adherence to TB treatment.

Introduction

More than 10 million cases of tuberculosis (TB) are reported each year globally [1]. In Malaysia, from 2010 to 2015, TB cases increased from 68.4 to 79.6 cases per 100,000 people [2]. In addition, according to a model projection, the observed and projected TB incidence in Malaysia will reach 300,000 cases in 2030 [3].

In Malaysia, directly observed therapy, short-course (DOTS) is a method to ensure medication compliance by having a trained health care worker or other designated individual provide the prescribed TB drugs and watch the patient take every dose. DOTS, which was implemented in 1994, has resulted in a treatment success rate from 76% in 2013 to 81% in 2017 [2]. However, this rate has remained below the recommended World Health Organization target of 90%. In addition, there is an increase in the prevalence of TB treatment default in Malaysia, which has ranged from 4% in 2010 to 4.8% in 2015 and to 5.6% in the latest study [4]. The increasing number of TB cases indicates that there are still issues and challenges that need to be addressed at all levels.

Specifically, the problems currently facing DOTS can be categorized according to the 3 main stakeholders. For patients with TB, the compulsory need for daily DOTS monitoring results in stigma by the public and absence from home or work responsibilities [5-7]. Health workers and policy makers are hesitant to fully implement DOTS, as there are inadequate human resources, increased TB management costs, less participation from lower management, and a lack of public awareness [8,9].

To address these challenges, the World Health Organization recommends the use of digital technologies to promote TB medication adherence [10]. Video directly observed therapy (VDOT) was introduced to replace physical DOTS and has proven to significantly reduce the cost of managing TB, improve patients' access to doctors, and be less disruptive to patients' work and family life [8,11-13]. According to many studies, VDOT is a more cost-effective method that significantly increases patient treatment adherence compared to conventional DOTS [14-18].

Although data on VDOT are becoming increasingly robust, the system has yet to be rigorously evaluated within low- and middle-income countries, especially regarding its feasibility [19]. This is quite worrying, as the implementation of VDOT requires complete access to hardware and internet connectivity, which some countries cannot afford [10]. However, in Malaysia, the number of smartphone users is growing and expected to reach over 33 million by 2024, with an 87.36% smartphone penetration, which suggests that VDOT can be implemented in Malaysia [20].

Making VDOT available via mobile apps could make drug monitoring more convenient and effective [21]. However, with the large numbers of mobile health apps in existence, the problem is often about the sustainability of their use [22]. As a solution, integrating gamification elements inside mobile apps can positively impact health and well-being, improve health behaviors and patient engagement, decrease health care use, and empower patients to self-manage their disease [23,24]. In addition, the use of real-time elements such as virtual reality and augmented reality has proven to increase learning effectiveness and behavior modification, correct medication identification, correct self-administration of medication, and support patient counseling practices [25-27].

Thus, in our Gamified Real-time Video Observed Therapy (GRVOTS) mobile app, the integration of gamification and real-time elements is expected to increase patient motivation. The purpose of this study was to validate the gamification, motivation, and real-time element in GRVOTS, a mobile app for VDOT, from the perspective of the service provider (expert review).

Methods

The mobile app prototype was developed from February 2021 to May 2022. The developmental process as a whole, including content and prototype development as well as content validation (nominal group technique [NGT]), was performed using the design science research process model [28].

Development

Content development of the prototype involved a few stages of literature review, mapping, and justification of the new framework. From the literature review, we identified 3 frameworks that could be used as features of app: gamification framework, video reality and motivation framework, and technology feature framework. The gamification component, as the foundation of the proposed gamified mobile app GRVOTS, will be based on the validated framework for the gamification of diabetes self-management called The Wheel of Sukr [29]. The framework consists of 8 components: fun, esteem, growth, motivation, sustainability, socializing, self-representation, and self-management. For the video reality and motivation framework, we used the attention, relevance, confidence, and satisfaction (ARCS) model of motivational design [30]. In terms of the mapping procedure, the ARCS model of motivational design can be combined with the gamification elements to foster motivation [31]. The dynamic nature of gamification, such as self-management, self-representation, and fun, can be equal to satisfaction in the ARCS model. Further, elements of gamification, such as esteem, reward, growth, and socializing, can be equal to the components of confidence in the same model. Subsequently, these 2 frameworks can be integrated where gamification elements are added to the categories of confidence and satisfaction that are based on the ARCS model. Table 1 shows the categories and subcategories of the proposed model in matrix form.

Game dynamics can improve user desire and motivation by establishing rules that encourage users to explore and learn about the apps [32]. Figure 1 shows a screenshot of the main function of the GRVOTS mobile app and its relation to our intended gamification, motivation, and real-time elements from the framework.

The GRVOTS mobile app is designed for 3 users—patients, supervisors, and administrators—where they interact with one another via the internet. All data inputted by the patients will be automatically collected by the server and viewed by the specific supervisor (health care worker) and TB management team to help them with clinical interventions. The proposed model presented in Figure 2 is based on the development of mobile apps for smartphones only.

Table 1. Matrix of the ARCS[a] model of motivational design and The Wheel of Sukr gamification model.

Model technique	Category			
	Attention	Relevance	Confidence	Satisfaction
ARCS (motivation)	• Active participation	• Link previous experience (motive matching) • Perceive with future usefulness (motive matching)	• Self-growth • Learning requirement • Success • Opportunities • Personal responsibilities	• Reward • Immediate application
The Wheel of Sukr (gamification)	—[b]	—	• Esteem • Reward • Growth • Socializing • Sustainability	• Self-management • Self-representative • Fun

[a]ARCS: attention, relevance, confidence, and satisfaction.

[b]Not applicable.

Content Validation via the NGT (Expert Review)

The NGT is a structured variation of a small-group discussion to reach consensus. Through the agreement of the description of the elements, the NGT was used in this research as a validation tool to evaluate the presence of the gamification and motivation components intended to be used in the app.

Sample Size

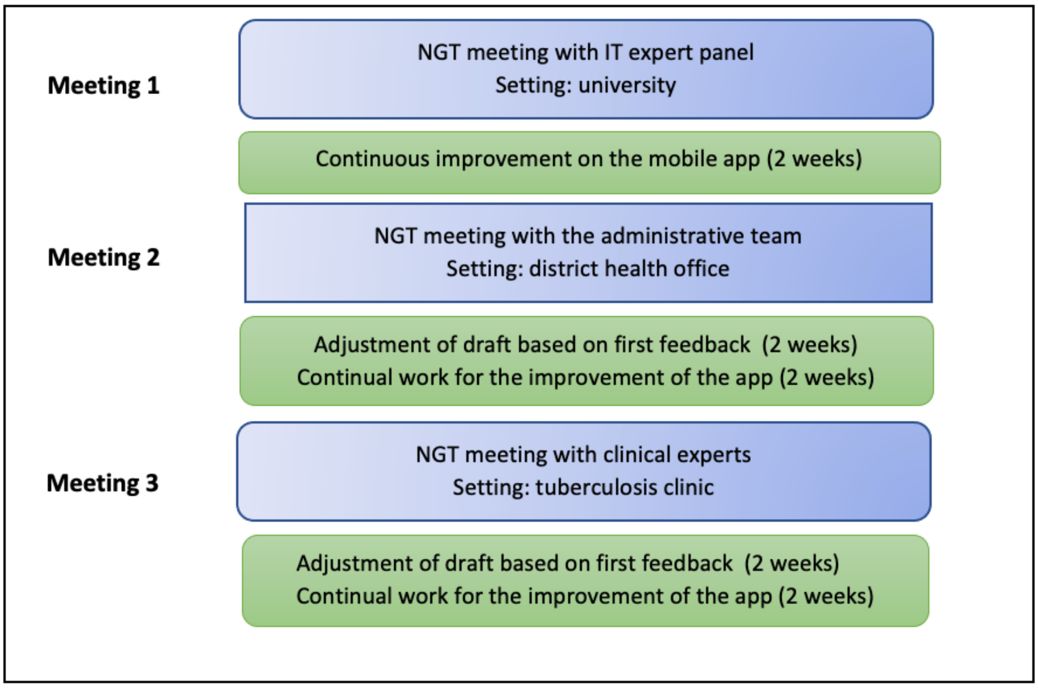
The NGT is a small-group technique suited to panel sizes of more than 10 people [33,34]. Therefore, there were 11 experts involved in this NGT session. A panel of experts was involved to validate the gamification elements in the GRVOTS app using physical meetings in 3 different settings.

Study Population Flow

This study was conducted iteratively in 3 meetings for a more comprehensive evaluation, as illustrated in Figure 3.

The criteria of the experts involved in the group were different according to each group. For the first group, IT experts were experienced and involved in mobile app development for at least 2 years and well versed in the gamification features of mobile apps. The second and third groups were composed of administrative and health care workers who were directly involved in managing patients with TB in the outpatient environment, respectively.

Figure 3. Flow of the modified nominal group technique (NGT) meetings.



Study Settings

The 3 NGT meetings were performed in 3 settings: at the university for the meeting with the IT expert panel, at the district health office for the meeting session with the administrative team, and at the TB clinic for the meeting with clinical experts.

Instrument for NGT

The instrument used in the NGT was a questionnaire, and the items were generated from a literature review based on 3 existing models as per the previous mapping. These models were developed into a panel expert checklist, and the questionnaire had 2 parts: Part A asked about the gamification-motivation–rea-time theory, The Wheel of Sukr [35], and the ARCS model, whereas Part B concerned the technology features by Anderson et al [36].

Implementation of NGT

The implementation of NGT involved experts who were selected according to the scope of the study. The workshop was conducted in a face-to-face meeting by a moderator [34]. The NGT workshop lasted approximately 2 hours. Before the workshop, the experts were given a week to use the app. Some of them experienced the task as a supervisor and some as a patient. They were required to send 3-4 VDOT videos. Table 2 shows the basic steps to carry out the NGT process, and Table 3 shows the 5 steps of data analysis for the NGT.

The data analysis process for the NGT was based on the percentage of agreement where an element is accepted when the percentage of agreement is 70% or more [37]. The 1-sample, 2-tailed *t* test was used to determine whether the mean (SD) percentage of agreement result on the gamification and motivation elements in this app was significantly higher than the percentage of agreement of 70%, with a level of significance (α error) less than .05. The software used at this stage was SPSS (version 28.0; IBM Corp) and Microsoft Excel.

Table 2. Steps of the specific guide to implement the nominal group technique session.

Step	Details
1. Introduction to problem statement and explanation	Moderator will brief the participants regarding the flow of the session.
2. Silent generation of ideas in writing	According to the checklist and GRVOTS[a] mobile app, participants were asked to answer the questionnaire using a Likert scale.
3. Round robin phase: sharing ideas	Participants were invited to share their answers in the round robin manner.
4. Discussion of ideas	Participants were asked to justify the need for the least prominent gamification and virtual reality elements in the GRVOTS mobile app prototype.
5. Voting and ranking	The voting was done by marking responses on a Likert scale from 1 (totally disagree) to 5 (totally agree). The calculation was done, and the elements were ranked accordingly.

[a]GRVOTS: Gamified Real-time Video Observed Therapies.

Table 3. The steps of data analysis for the nominal group technique (NGT) steps.

Step	Activity
1	Ensuring the number of participants (experts) involved in the study
2	The formation and calculation of score value is based on the template data analysis of the NGT
3	Convert score values into percentage form to obtain the percentage of agreement:
	where A=the total number of experts and B=Likert scale used, ie, 5 points
4	Determine the acceptance of components and elements based on the percentage of agreement
5	Determine the positions of the elements according to the percentage of agreement

Ethics Approval

Ethical approval was obtained from the Universiti Teknologi MARA Ethical Board and Medical Research and Ethics Committee, Malaysia: NMRR-21-1016-58994 (IIR).

No informed consent was taken in this study as the data were only retrieved retrospectively from the database and no identifiers were collected for this study.

Results

Mobile app development with the integration of gamification and real-time elements was performed via a literature review, and the content validation of the component was performed via the modified NGT.

Prototype

The final beta version of the mobile app used Android as the platform. The prototype was designed to be used by 3 users—patients, supervisors, and TB managers—and each user had a different role in the program. This mobile app's main function is to provide patients with a way to record daily DOTS intake via video (VDOT) as well as medication side effect reporting. After patients log in, they are directed to set up their personal profiles and learn how to use the VDOT medication reminder, which is the main activity. After each VDOT session is uploaded, it is followed by pop-up motivational quotes as well as the movement of the progress meter indicator.

The accumulated points collected from the progress meter will be translated into badges in the progress report theme. Subsequently, a daily pop-up message will also be the main reminder for the next medication, and patient will be asked if they noticed any adverse reactions to previous medication, with a selection of options concerning their symptoms. The ability to report adverse effects gives patients access to their own medication diaries, which can be reviewed during medical visits. Throughout the TB treatment journey, the progress report theme will help patients track their journey and redeem the internal and external rewards offered.

Every VDOT report and any side effects noted by patients will be verified by the supervisor as a feedback interaction. This feature enables supervisors to regularly check and understand the patients' progress as well. In addition, patients can always go to other main theme of "knowledge" to continuously learn more about TB treatment and nutrition.

The app provides different users with access to different functions and main menus. In the patients' main menu, there are 4 main themes for VDOT. Information regarding the app, progress report, and side effect reporting is shown in Figure 4. For the supervisors' main menu, there are 2 menus, one to validate the VDOT report and another to validate the side effects, as shown in Figure 5.

Figure 4. Screenshots of the GRVOTS app for patients. GRVOTS: Gamified Real-time Video-Observed Therapies.

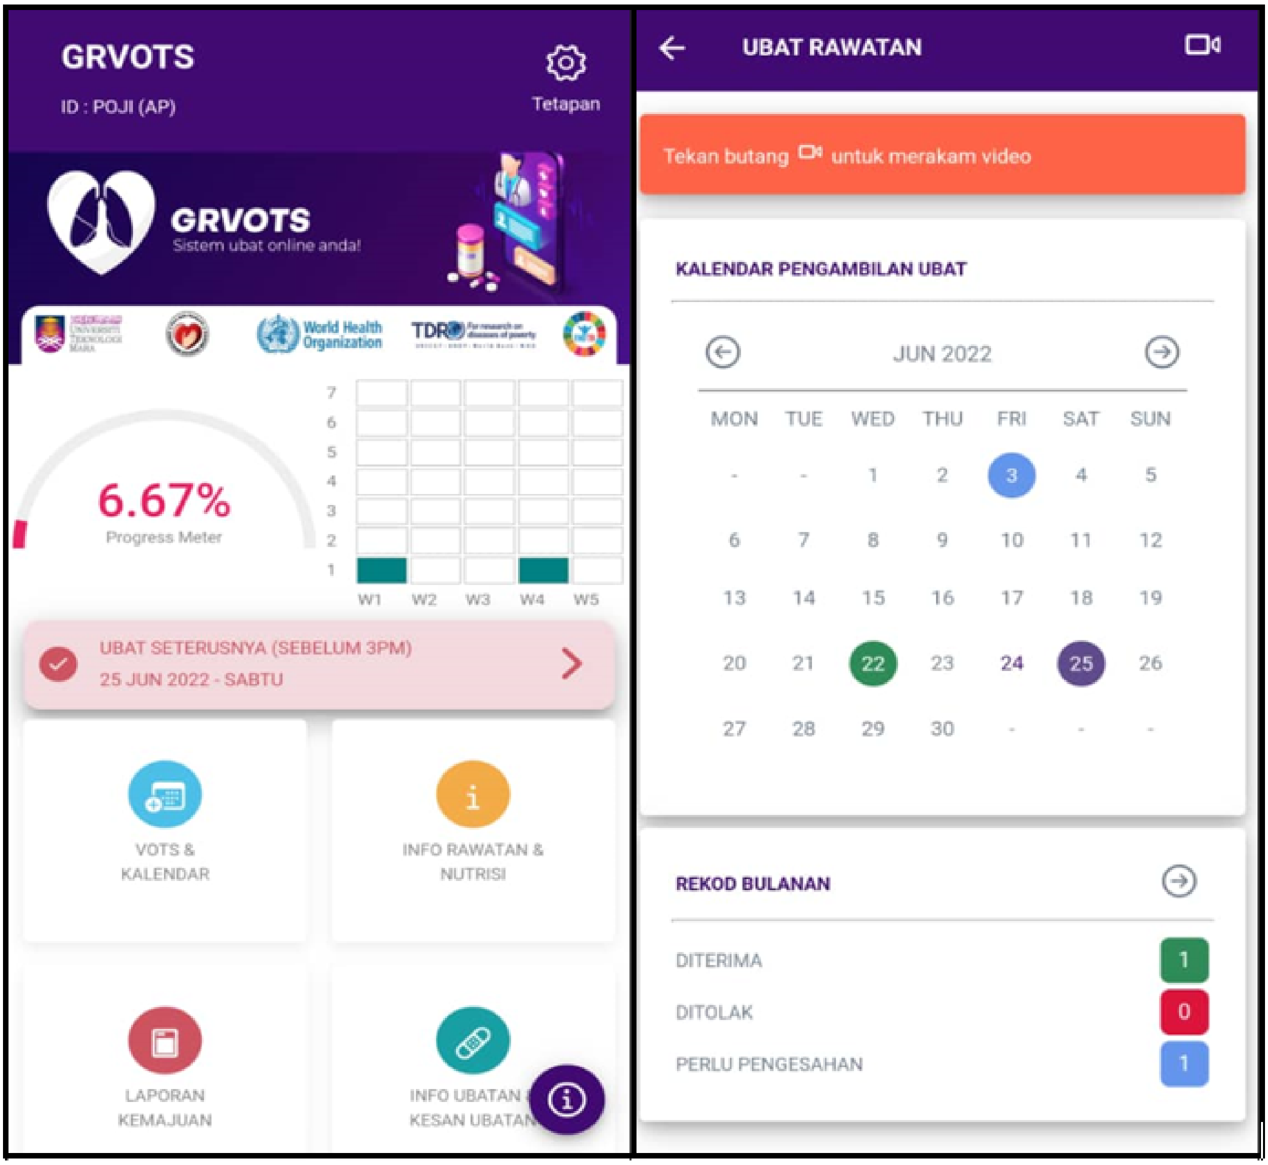


Figure 5. Screenshots of the GRVOTS app for supervisors to monitor patients. GRVOTS: Gamified Real-time Video-Observed Therapies.

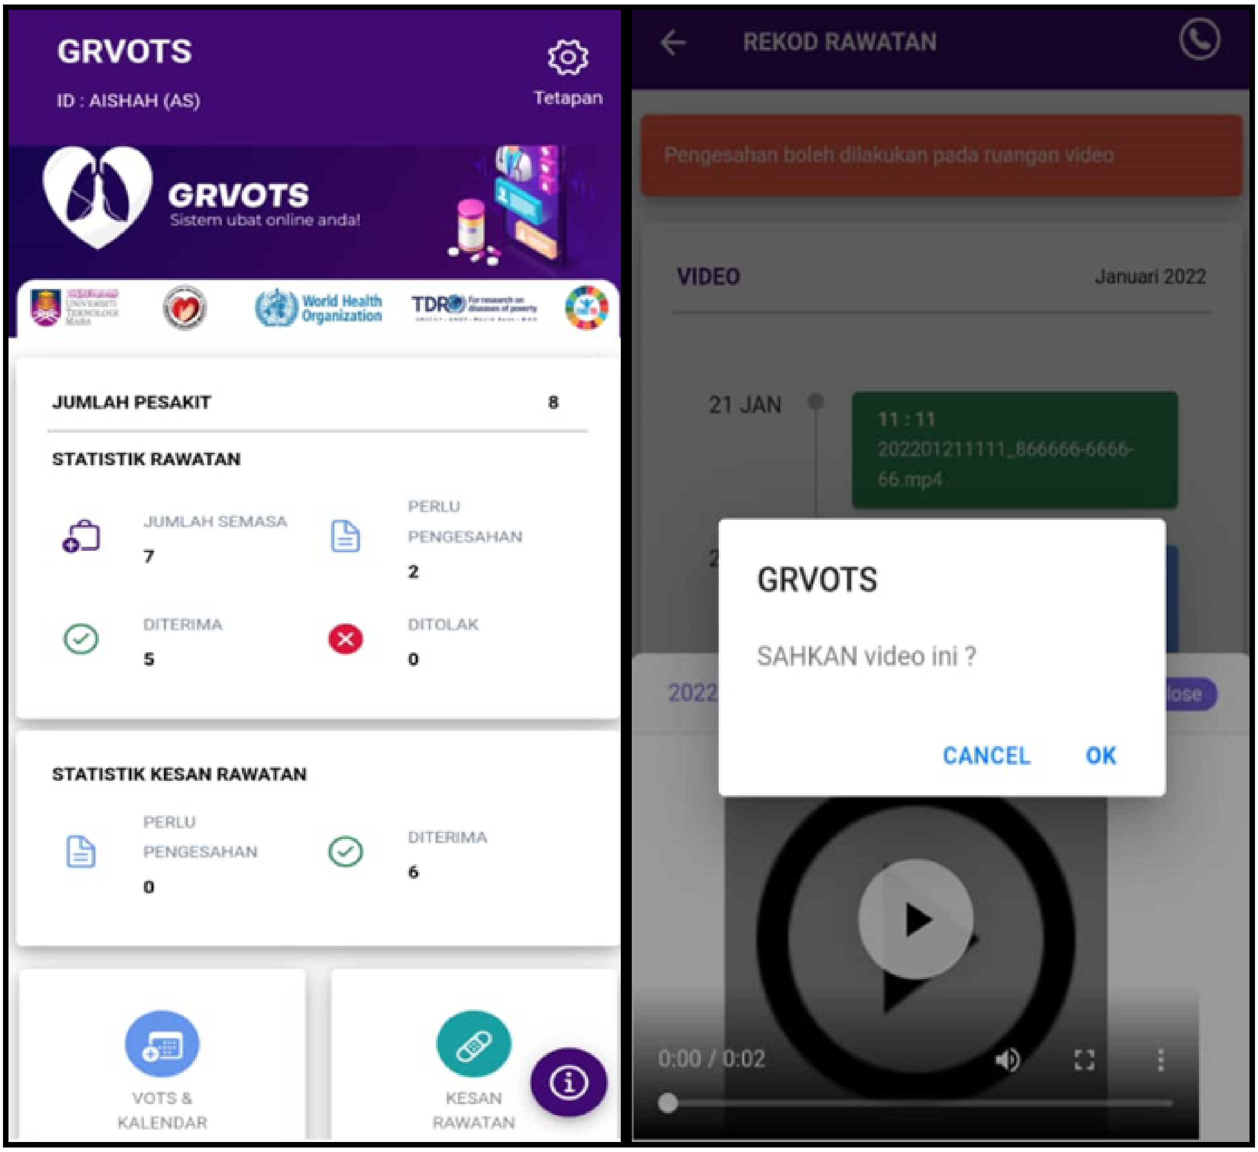

NGT Output for Content Validation

A panel of 11 experts were involved in the modified NGT, including 2 gamification experts, 2 public health experts, 1 chest physician, 2 medical officers, 3 medical assistants, and 1 staff nurse. They were asked to rank the app's elements based on the expert panel checklist. Tables 4-6 show the results and rankings of gamification, motivation, and technology feature elements via the NGT.

The total percentage of agreement among experts was 97.95% (SD 2.51%), which was significantly higher than the minimum of 70%, with a difference of 27.947% (95% CI 26.74%-29.15%; *P*<.001). The *t* test confirmed the validity of all gamification and motivation components in the app.

Table 4. Results of the nominal group technique for gamification elements.

No	Main element	Explanation element	Percentage of agreement, mean (SD)	Acceptance result	Ranking
1	Self-management	• This app has a dashboard with a progress meter, medication reminders, and a VDOT[a] feature to help patients self-manage their medication. • This app has adverse effect reporting to help patients self-manage their reactions to medications.	98 (2.22)	Accepted	4
2	Self-representative (avatar)	• This app has a personalized name on the dashboard along with the roles of the user.	97 (0.00)	Accepted	6
3	Fun	• This app has a progress meter, a progress bar, motivational quotes, and badge rewards that add a fun element for the patient.	96 (0.8)	Accepted	8
4	Esteem	• This app has a progress meter, a progress bar, motivational quotes, and a feedback mechanism aimed at boosting patients' self-esteem.	99 (1.386)	Accepted	3
5	Growth	• This app has a feedback mechanism that helps patients with self-growth. • This app empowers patients' self-growth with medication information.	100 (0.00)	Accepted	1
6	Sustainability (trigger)	• This app has medication reminders aimed at the sustainability of its use.	97 (0.00)	Accepted	7
7	Motivation	• This app has a progress meter, a progress bar, and badge rewards that boosts patient motivation.	98 (2.358)	Accepted	5
8	Socializing	• This app has a feedback mechanism that enables patient-supervisor communication.	100 (0.00)	Accepted	2

[a]VDOT: video directly observed therapy.

Table 5. Results of the nominal group technique for motivation elements.

No	Main element	Explanation element	Percentage of agreement, mean (SD)	Acceptance result	Ranking
1	Attention	• This app has medication reminders, a VDOT[a] feature, and adverse effect reporting to hold patients' attention and achieve active participation. • This app has a progress meter that alerts patients regarding the status of their performance. • This app has a performance indicator (progress bar) that alerts patients about medication compliance over time.	99 (1.869)	Accepted	3
2	Relevance	• This app has a VDOT feature that links patients' current remote and previous in-person experience of taking medication.	98 (0.00)	Accepted	4
3	Confidence	• This app has motivational quotes to boost patient confidence.	100 (0.00)	Accepted	1
4	Satisfaction (achievement)	• This app has a VDOT feature, adverse effect reporting, a progress meter, a progress bar, motivational quotes, and badge rewards that help patients feel satisfied with their daily medication compliance.	99 (1.361)	Accepted	2

[a]VDOT: video directly observed therapy.

Table 6. Results of the nominal group technique for technology feature elements.

No	Main elements	Explanation element	Percentage of agreement, mean (SD)	Acceptance result	Ranking
1	Automation	• This app has automated medication reminders, pop-up notifications, and reminders to both the patient and supervisor that made it easy to use.	97 (0.635)	Accepted	5
2	Ease of use (automation)	• This app has automated pop-up notifications to remind the supervisor to approve the adverse effect reports.	100 (0.00)	Accepted	1
3	Real-time feature	• This app has a real-time stamped VDOT[a] feature.	89 (0.00)	Accepted	7
4	Self-guided video	• This app has a self-guided VDOT tutorial video that can benefit the patient. • This app has self-guided adverse effect symptom choices that can help patients identify symptoms. • This app has a self-guided feature to provide the patient with knowledge regarding nutrition and medication. • This app has a good tutorial on how to use the app.	99 (1.361)	Accepted	3
5	Aesthetic	• This app has good aesthetic features.	97 (0.00)	Accepted	6
6	Navigation	• This app has a good flow of navigation from one page to another.	100 (0.00)	Accepted	2
7	Tactile feedback	• This app has good tactile or haptic feedback.	98 (0.00)	Accepted	4

[a]VDOT: video directly observed therapy.

Discussion

This comprehensive GRVOTS mobile app was developed based on the integration of gamification and real-time motivational elements of autonomy, competence, relatedness, attention, relevance, self-control, confidence, and satisfaction. These components were successfully validated and significant.

Mobile App Developed

Our GRVOTS mobile app was able to motivate patients toward medication adherence using the ARCS model of motivation, which was translated via its gamification and motivation features. First, the interactive VDOT feature can stimulate the patient's feelings of attention and arousal. Second, by linking the previous experience of medication intake physically with the experience of using GRVOTS, the element of "relevance" can also be instilled in the patient. When patients perceive a high sense of relatedness, they are more likely to exhibit higher engagement with a program [38]. By providing goals along the journey toward medication adherence, the app can instill confidence and self-belief, especially when the patients can digitally see their previous VDOT report and a progress meter of treatment success. As they use GRVOTS to monitor their medication intake, patients experience more freedom of choice and self-control, and the results of treatment adherence will subsequently reinforce the app's value. The last element of "satisfaction" can also be realized when patients comply with the use of GRVOTS and receive rewards in the form of badges and progress meters.

Content Validation via the Modified NGT

The results of the modified NGT showed that all the components obtained from the literature and related model were validated by the experts during the NGT session, as shown in Tables 4-6. Based on the results, the elements were prioritized based on the percentage of acceptance. Considering these rankings, some of the GRVOTS functions were improved to provide a better mobile app for the next pilot study.

According to the results for the gamification elements, the growth element received the highest scores, whereas fun received the lowest scores. By definition, "fun" aspects within the gamification elements in this GRVOTS app are exemplified by a progress bar, a progress meter, inspiration quotes, and badge rewards. The fun element was voted as a less visible element in this app, perhaps due to many factors, such as the perception of fun, which varies for different people, as well as the nature of serious games, which does not prioritize the fun element. A number of studies have described that the perception of gamification features differs according to the gamer type, gender, and personality of the player. For instance, extroverts like rewards and leaderboards, which appear to be more entertaining, but introverts prefer badges and feedback [39-41].

Health apps are also considered serious games that are played for purposes other than pure entertainment [42]. In this case, having a fun component is not a priority. According to a study regarding serious games, other elements, such as explicit learning tasks, instruction, and support built into the game or added by teachers, may be more important than having fun while playing [43].

For the motivation elements of the ARCS model, the highest ranked element was confidence and the lowest was relevance. It is suggested that when patients perceive a high sense of relatedness, they are more likely to exhibit higher engagement with the program [38]. In mobile apps, relatedness is seen as a feature of leaderboards or chats that encourages engagement and collaboration to achieve a particular objective [41]. However, in this GRVOTS mobile app, the relevance element is evidenced by allowing daily communication between patients and supervisors via the VDOT and adverse event reporting components without the leaderboard or chat features. This is because most of our patients with TB refused to disclose their condition and communicate with other patients due to the stigma associated with the disease.

For the technology feature elements, the highest ranked was ease of use and the lowest was real-time features. There are 2 type of VDOT: live VDOT, also known as synchronous VDOT, in which patients and providers interact in real time [12,44]; as well as asynchronous technologies that record, upload, and digitally store videos for future review [11,19,45]. Synchronous VDOT has the advantage of human interaction but is not a feasible option, as patients and workers need to find time to meet. Asynchronous VDOT is more flexible but can be manipulated easily by sending the same recorded video. Thus, apps with real-time features ensure the originality of the video and simultaneously generate a greater degree of user engagement [25-27]. Although the real-time feature in our app provides details concerning the time and date of the video, feedback from the experts indicated that we should time stamp the videos so that they can be identified more easily later. Since users found it challenging to determine if their VDOT session was successfully uploaded or not, the addition of an upload bar was also recommended.

Strengths and Limitations

The GRVOTS mobile app can benefit users in many ways. For patients with TB, the app can help patients gain self-control, boost their self-esteem, and motivate them to take their medications. For health care workers, this app made it easier for TB system management to detect DOTS defaulters and manage them accordingly. As a portable device, mobile apps enable monitoring that can be done anywhere, saving money and time and boosting patient engagement with the DOTS program. In summary, this app can also initiate a patient self-care system and reduce dependency on health care providers such as doctors and nurses. The limitation of this study is that the mobile app prototype is only being developed for the Android platform because of time and logistics. The app does not have a virtual reality feature, and improvements are needed in the future. This study conducted the validation of the gamification and motivation elements only from the perspective of the experts and not from the perspective of patients, which may limit the review's validity; an analysis regarding its usability among patients will be conducted in the future.

Recommendation

In the future, GRVOTS should also be available on other platforms, especially the iPhone Operating System. The language options should also include English, Chinese, and Tamil, as these languages are frequently used in multiethnic communities in Malaysia. The use of various languages will expand the benefits to more users. This will enhance knowledge transfer and improve users' understanding. Next, a usability study to access the user experience will be conducted, followed by an effectiveness study via a single-arm intervention study, in which patients will use the app for DOTS during intensive phase up to 2 months monitoring, followed by an assessment at 3 time intervals to evaluate their medication adherence, motivation, and the usability of the app.

Conclusion

More comprehensive and efficient TB system management via VDOT mobile app monitoring is a way to improve patient treatment adherence. According to the literature review, gamification elements can motivate patients; thus, by integrating the uniqueness of gamification and motivation elements in an app, gamification will increase patient motivation, ensure the sustainability of use, and ultimately increase patient adherence. In addition, our GRVOTS mobile app connects up to 3 users (eg, patients, supervisors, and administrators) remotely and enable DOTS monitoring to be performed from anywhere. Based on the study findings, the GRVOTS mobile app has been validated by the expert panel as having the intended elements of gamification, real time, and motivation. Next, a usability study of the GRVOTS mobile app will be conducted to measure the user experience among patients, followed by a single-arm intervention study to assess the app's effectiveness in increasing patient motivation and medication adherence in TB treatment.

Acknowledgments

The author would like to thank to the Director General of Health Malaysia for his permission to publish this study. We give many thanks also to the Universiti Teknologi MARA.

This study is funded by the Joint TDR/World Health Organization Western Pacific Region Small Grant Scheme for Implementation Research.

Data Availability

All data supporting the study findings are within the manuscript. Additional details information and raw data are available from the corresponding author on reasonable request.

Authors' Contributions

SAA and NI conceived the project. SAA contributed to data collection. SAA, NI, and YZ contributed to data analysis. SAA, II, and NHMZ contributed to mapping the apps architecture. NI supervised the study. The manuscript was written mainly by SAA with the approval of all authors. All authors read and approved the final version of manuscript for publication.

Conflicts of Interest

None declared.

Abstract

Background: Inuit youth in Northern Canada show considerable resilience in the face of extreme adversities. However, they also experience significant mental health needs and some of the highest adolescent suicide rates in the world. Disproportionate rates of truancy, depression, and suicide among Inuit adolescents have captured the attention of all levels of government and the country. Inuit communities have expressed an urgent imperative to create, or adapt, and then evaluate prevention and intervention tools for mental health. These tools should build upon existing strengths, be culturally appropriate for Inuit communities, and be accessible and sustainable in Northern contexts, where mental health resources are often scarce.

Objective: This pilot study assesses the utility, for Inuit youth in Canada, of a psychoeducational e-intervention designed to teach cognitive behavioral therapy strategies and techniques. This serious game, SPARX, had previously demonstrated effectiveness in addressing depression with Māori youth in New Zealand.

Methods: The Nunavut Territorial Department of Health sponsored this study, and a team of Nunavut-based community mental health staff facilitated youth's participation in an entirely remotely administered pilot trial using a modified randomized control approach with 24 youths aged 13-18 across 11 communities in Nunavut. These youth had been identified by the community facilitators as exhibiting low mood, negative affect, depressive presentations, or significant levels of stress. Entire communities, instead of individual youth, were randomly assigned to an intervention group or a waitlist control group.

Results: Mixed models (multilevel regression) revealed that participating youth felt less hopeless (*P*=.02) and engaged in less self-blame (*P*=.03), rumination (*P*=.04), and catastrophizing (*P*=.03) following the SPARX intervention. However, participants did not show a decrease in depressive symptoms or an increase in formal resilience indicators.

Conclusions: Preliminary results suggest that SPARX may be a good first step for supporting Inuit youth with skill development to regulate their emotions, challenge maladaptive thoughts, and provide behavioral management techniques such as deep breathing. However, it will be imperative to work with youth and communities to design, develop, and test an Inuit version of the SPARX program, tailored to fit the interests of Inuit youth and Elders in Canada and to increase engagement and effectiveness of the program.

Introduction

Inuit are Indigenous Peoples of the Arctic and subarctic regions of Greenland, Alaska, and Canada. In Canada, they are recognized as a distinctive group of Indigenous Canadians—alongside First Nations and Métis—primarily occupying Labrador, Northern Quebec, the Northwest Territories, and Nunavut. Pervasive youth suicide is the most urgent challenge facing Inuit in Canada today, a public health emergency of epidemic proportions [1,2]. Death by suicide in Inuit communities has spiked over the last century [3,4], currently at 9 times the national average and with male youth aged 15-24 being the most affected [5]. Under the fallout of colonialism, Inuit youth in Canada face more mental health challenges than non-Indigenous populations, due to cross-generational impacts of residential schools and multiple continuing systemic inequities [6,7]. The government era of the 1950-60s and beyond, during which the Canadian government forced Inuit into aggregated settlements, imposed a welfare state, and separated Inuit children from their families, has had lasting effects on relationships within family and community, strained kinship across generations and between genders, and left generational gaps in mental health–supporting communications between youth and their parents and Elders [3]. Further, Indigenous youth in general tend to be among those most reluctant to seek help when experiencing distress [8]. This lack of help-seeking may be due in part to a struggle to recognize symptoms of depression, which may present as anger in Inuit youth [4,9].

Those living in remote Northern communities often go without access to the mental health supports available elsewhere in Canada [10] for a number of reasons. First, few health care professionals train or practice in the Canadian North, and frontline workers often experience "burnout" due to excessive workload and personnel shortages [11]. As a result, youth in Nunavut have limited access to specialized services and are often sent out of their communities when they experience severe mental health symptoms [10,12-14]. Finally, adolescents in small, remote communities are especially prone to avoiding professional health services, as they may fear compromised confidentiality due to a lack of privacy and the stigma associated with mental illness. One study found that of all youth who committed suicide in Nunavut in the past decade, only 12% had received medication and 17% had been hospitalized in relation to their mental health, while 89% had not received any mental health support at all [14,15]. Given the reality that there are relatively few frontline mental health workers available in Nunavut communities and stigma impeding access to existing services, it is imperative to identify and develop preventive interventions for depression that are not only effective and culturally appropriate, but also easily accessible [11].

To address the dearth of available in-person mental health support options, this study aims to examine the usefulness of an e-intervention, SPARX [16,17], in Nunavut. SPARX (Smart, Positive, Active, Realistic, X-Factor thoughts) is a psychoeducational *serious game* (an e-intervention that utilizes gaming for serious purposes) [18] that teaches established cognitive behavioral therapy (CBT) strategies and techniques across 7 levels or modules (see Figure 1 for an example). The game is designed to address depressive symptoms in youth by helping them cope with negative thoughts and feelings, represented in the game as GNATs—gloomy negative automatic thoughts (Figure 2) [16]. SPARX was originally designed and developed at the University of Auckland with the specific needs of certain underserved groups of youth in mind, including Māori Rangatahi, the Indigenous young people of Aotearoa, New Zealand. SPARX's development included a Māori co-creator (MS), input from Māori CBT experts, and cultural guidance from a *kaumatua* (ie, respected Elder). Moreover, the game development company was led by a Māori woman and the voice actor (virtual therapist/instructor) was a Māori; additionally, the Māori symbolism, presented in a fantasy format, was woven throughout the intervention [17]. With these very specific cultural foundations in mind, the goal of this pilot study was to evaluate the effectiveness of the original version of SPARX in boosting resilience against depression among Inuit youth in Canada in 11 Nunavut communities. We aimed to assess whether Inuit youth who completed the SPARX program experienced increased resilience and showed a decrease in risk factors related to depression, specifically cognitive distortion, emotional dysregulation, hopelessness, rumination, self-blame, other-blame, and catastrophizing [19].

The Nunavut Territorial Department of Health sponsored this study, and a team of Nunavut-based community mental health staff facilitated youth's participation in an entirely remotely administered pilot trial. A total of 48 youths from 11 Nunavut communities completed an evaluation of the utility of SPARX in modifying dysfunctional cognitions, reducing symptoms of depression, and enhancing resilience. All youth completed conventional pre- and postintervention measures assessing their current mental health status. Measures were selected based on their use in earlier effectiveness studies [16,17]. Quantitative and qualitative data were collected and used to evaluate the program's preliminary effectiveness based on the following hypotheses:

- Youth who completed the SPARX program were expected to experience a decrease in depressive symptoms as well as risk factors related to depression, as measured by the Centre for Epidemiologic Depression Scale-Revised (CESD-R), the Hopelessness Scale for Children (HSC), and the Cognitive Emotion Regulation Questionnaire-Short (CERQ-Short; see the "Measures" section).

- Youth who completed the SPARX program were expected to experience an increase in factors related to resilience, as measured by the shortened, 12-item version of the Child and Youth Resilience Measure (CYRM-12).

Methods

Participants

All 25 Nunavut communities were initially recruited to participate in this study; 11 communities (Baker Lake, Cambridge Bay, Grise Fiord, Hall Beach, Igloolik, Kugaaruk, Kugluktuk, Naujaat [Repulse Bay], Taloyoak, Qikiqtarjuaq, and Resolute) completed the pilot trial. The remaining 14 communities did not complete data collection because of an inability to recruit youth, because there was no local adult facilitator able to support youth, or because facilitators had to leave the project due to extraneous circumstances. Communities were chosen based on feasibility and required both an interested community facilitator with the time to commit to SPARX and youth who were interested in the project. As many as 3-4 youths were recruited in each community with a projected participant count of 40.

Youth participants were between the ages of 13 and 18 and had been identified by the community facilitators as exhibiting low mood, negative affect, depressive presentations, or significant levels of stress. Youth had to demonstrate sufficient English language comprehension to use and understand SPARX.

Although such an approach is not reflective of Indigenized research generally, these inclusion criteria were suggested by local facilitators due to the heavy use of the English language within the SPARX game. Initially, youth were excluded if they showed limited cognitive abilities, psychotic presentation, severe depression, or elevated suicide risk, or if they were currently receiving or had previously received CBT, interpersonal therapy, or antidepressant medication within the past 3 months. However, due to safety and ethics concerns about vulnerable youth feeling left out, at the discretion of local mental health experts on the team, these exclusion criteria were relaxed. The 25 facilitators were appointed by staff at the Department of Mental Health, Government of Nunavut. In total, 24 of 48 youths who initially signed up completed the study (see the "Design" section for attrition rates at each time point).

Procedure

A preproject planning meeting was held in Toronto with managers of the Territorial Department of Health, a team of community mental health staff from Nunavut, and potential on-site facilitators on March 27, 2014. Procedural aspects of the SPARX pilot project were based on contributions and feedback from attendees of this meeting. The meeting focused on the importance of the SPARX project in Nunavut communities, how the SPARX project could achieve cultural appropriateness, and what traditional and cultural knowledges must be incorporated to gain youth trust and participation. In a collaboration among Nunavut Department of Mental Health staff, community stakeholders, and the coordinating team at York University, the design described in this work was adopted at the planning meeting.

Ethics Approval

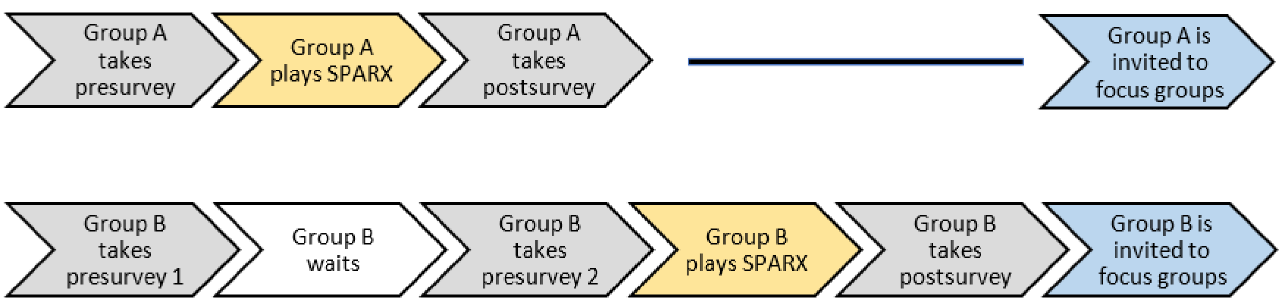
Approval for the SPARX pilot was obtained through the Human Participants Sub-Committee of the York University Office of Research Ethics (York University HPRC Certificate No. 2015-070). Approval was also obtained from the university's Advisory Group for Research Involving Indigenous Peoples. This subcommittee is guided by Chapter 9 of the Tri-Council Policy Statement "Research involving the First Nations, Inuit, and Métis Peoples of Canada," and its own Guidelines for Research Involving Indigenous Peoples. In addition, the research team received approval in the form of a research license from the Nunavut Research Institute, which represents all 25 Nunavut communities (license number 02 004 15N-M).

Design

A modified randomized control approach was adopted for this trial. Community facilitators, responsible for recruiting youth and facilitating gameplay, were trained prior to youth recruitment and played SPARX to familiarize themselves with the game. Once training was complete, community facilitators recruited youth, secured consent, and administered preintervention measures. Entire communities, instead of individual youth, were randomly assigned to an intervention group (group A) or a waitlist control group (group B), which is why a modification was made to the randomized control trial, as described in the following section.

The sequence of SPARX play differed for the youth depending on whether they were in group A or group B (Figure 3). Both groups completed the preintervention surveys at time 1, the beginning of the study. Group A youth then began to play SPARX for 7 weeks while group B waited. During their wait time of 7 weeks, group B youth were not required to participate in any SPARX activities or meet with the community facilitator, and they were provided with no additional SPARX-related information. After 7 weeks (time 2), group A youth completed postintervention surveys, while group B youth began their engagement with SPARX by first completing an additional set of preintervention surveys, immediately followed by 7 weeks of SPARX play. Once group B youth completed their SPARX gameplay (time 3), they next completed postintervention surveys. Attrition rates were 35% (7/20) for group A (the intervention group) at time 2, 32% (9/28) for group B (the waitlist control group) at time 2, and a further 47% (9/19) for group B at time 3. This was due to high community facilitator turnover, timing of holidays, loss of interest, and arising community crises that took facilitators away from supporting SPARX usage. Similar attrition rates are not uncommon in pilot studies in remote communities.

Figure 3. Sequence of SPARX play.



Youth played SPARX on the laptops in either the community facilitator's office or in an office in their school. Youth were asked to engage in SPARX play once a week; however, due to complications in some communities (eg, crises, snowstorms), some youth played more or less frequently than this. Youth engaging in SPARX were always supported and accompanied by a community facilitator, given the exploratory nature of this novel study. This assistance was provided to ensure that any support youth needed with gameplay or with their mental health difficulties was prudently available while this new intervention was being piloted. The sequence of SPARX play is detailed in the following sections.

Measures

Pre- and postintervention surveys consisted of the same set of measures at both time points. Measures were either completed online via SurveyMonkey or in printed paper format. Community facilitators were on-site with the youth while they completed the measures to provide support such as reading questions out loud to the youth, or talking through answers if any youth felt vulnerable, at risk, or triggered by the content of the questions. Measures were selected based on their relevance; use in earlier, related studies; established psychometric properties for youth; sensitivity to change over time; ease of administration; length and clarity; and constraints based on funding sources.

The goal of this pilot study was to replicate, as best as possible in this new context, the studies conducted with Māori youth [16] to assess the potential usefulness of SPARX as an intervention with Inuit youth in Canada. It was clear to the researchers that should funding subsequently be obtained for a more comprehensive study, more culturally appropriate questionnaires would then be developed, together with Inuit communities, to assess youth depression and resilience [20]. As of the time of the writing of this paper, that has indeed happened, and a study of a culturally adapted version of SPARX for Inuit youth is underway [21]. In the absence of culturally appropriate outcome measures to assess mental health factors related to suicidality in Inuit youth, and to remain as consistent as possible with existing studies of SPARX conducted in New Zealand, the following primary outcome measures were chosen to assess changes in depression, hopelessness, resilience, and cognitive emotion regulation within these communities.

The CESD-R [22] is a succinct, 20-item, self-report scale that aims to measure current depressive symptomatology. Each item is a symptom associated with depression. The CESD-R has acceptable internal consistency (Cronbach α=.85) and test-retest reliability [23]. Validity was also established based on correlations with other assessment tools [24]. A sample item includes, "In the past week, I was bothered by things that don't usually bother me." Although it has not yet been evaluated within Inuit communities, the CESD-R is the most commonly used measure of depression among Indigenous youth, and has demonstrated a good model fit, with a root-mean-square error of approximation [25] of 0.6.

The HSC [26] contains 17 true-false items, which describe negative future expectations and negative present attitudes. Scores range from 0 to 17. Internal consistency is α=.97 and test-retest reliability is r=0.52. The HSC correlated positively with depression (r=0.58) and negatively with self-esteem measures (r=–0.61) and social skills (r=0.39) [26]. A sample item includes, "I might as well give up because I can't make things better for myself." This questionnaire has good internal consistency with other Indigenous youth (α=.86) but has not been evaluated with Inuit communities [27].

The CERQ-Short [19] is an 18-item measure used with adolescents and has good psychometric properties. It is composed of 9 coping styles, which are each coded as separate subscales of emotion regulation. These include Self-blame (score 1), Acceptance (score 2), Focus on Thought/Rumination (score 3), Positive Refocusing (score 4), Refocus on Planning (score 5), Positive Reappraisal (score 6), Putting Into Perspective (score 7), and Catastrophizing (score 8). Cronbach α coefficients range from .68 to .83 for the 9 subscales. Test-retest reliability ranged [19] from r=0.48 to 0.65. A sample item includes, "I keep thinking about how terrible it is what I have experienced." The CERQ-Short has been used with selected Indigenous populations; however, no official reliability or validity values have been published and it has not been evaluated with Inuit communities.

The CYRM-12 [28] is a 12-item self-report measure that includes 3 dimensions (Individual, Relational, and Contextual) that reflect the major categories of resilience. Raters choose whether the sentences describe them and endorse either "No," "Sometimes," or "Yes." The scale was developed for use with youth between ages 13 and 22 [28]. Internal consistency had Cronbach α ranging [29] from .65 to .91. A sample item includes, "When things don't go my way, I can fix it without hurting myself or other people (for example hitting others or saying nasty things)." The CYRM-12 has frequently been used with Indigenous populations, showing good content and internal validity, but has not been evaluated with Inuit communities [28].

Data Analysis

Because of the challenges encountered with youth recruitment, and the knowledge that an ideal sample size would likely be unattainable, no formal power calculations were conducted prior to beginning this study. To analyze mental health changes in Inuit youth in Canada over time, as measured through the 4 questionnaires, paired samples *t* tests (both 1- and 2-tailed—see below) comparing pre- and postintervention outcomes and repeated measures ANOVAs were conducted via SPSS Statistics version 26 (IBM Corp). ANOVAs allowed for examining the effect of time interacting with the intervention group or the waitlist control group. Paired samples *t* tests and ANOVAs pooled group A and group B data to account for missing data across groups and fewer completed postmeasures from group B youth. As a result of pooled data, there was some loss in accuracy due to the omission of select cases that did not fit the structure required by these simpler statistical methods.

Given the structure of the study—the comparison of the intervention group (group A) and the waitlist group (group B) at all (up to 3) time points for the pre- and postmeasures (group A: premeasure at time 1, postmeasure at time 2; group B: premeasure at time 1, premeasure at time 2, and postmeasure at time 3)—mixed models (multilevel regression) using pooled data were conducted via SPSS software. Multilevel regression models were appropriate given their ability to detect individual differences across different treatment options (time points for youth in group A vs group B). Results of the multilevel regression models are considered the most accurate as they use all the nonmissing data (important with a small sample size), reflect the full design of the study, and allow for comparison between group A and group B at different time points. Multilevel regression models were fit with (1) a randomly varying intercept for each youth to account for their differing initial levels of personally identified health and (2) an intervention indicator variable (0 for not having started playing the SPARX program vs 1 for completing the treatment of playing SPARX) to account for the effect of the treatment (ie, engaging in SPARX). A time variable was not needed as there were at most 2 (group A) to 3 (group B) measurement occasions with a horizontal, time-independent trajectory after accounting for the effect of the intervention. The assumptions of the mixed models were checked (eg, normality of the residuals) and found reasonable.

Researcher Characteristics

Enduring colonial approaches to research in Canada have severely diminished Inuit sovereignty with respect to research activity in the Inuit homeland [30]. In the spirit of accountability and reconciliation, we believe it is important to acknowledge that the research team is diverse and consists of Indigenous and non-Indigenous team members. CS, our Inuit community liaison, is an Inuk and a longstanding research partner with YB and her team of researchers at York University. MS is a Māori researcher who co-developed the SPARX program with Indigenous youth in New Zealand. JB is an Indigenous status First Nations student, born and raised in Tyendinaga/Kenhteke Mohawk Territory. YB, LL, JRH, HM, and MFGL are White researchers from the South (*Qallunaat*).

Results

Overview

Table 1 provides a summary of the baseline and postintervention results for participants in groups A and B. Mean scores and the SDs for the 4 outcome measures (by subscale for the CERQ-Short) are provided below.

Table 1. Descriptive statistics by group and time point.

Outcome measure	Group A time 1 (n=20), mean (SD)	Group A time 2 (n=13), mean (SD)	Group B time 1 (n=28), mean (SD)	Group B time 2 (n=19), mean (SD)	Group B time 3 (n=10), mean (SD)
CYRM-12[a]: Resilience	44.70 (8.04)	41.07 (10.22)	43.32 (7.54)	43.62 (9.44)	45.30 (8.42)
HSC[b]: Hopelessness	4.52 (2.75)	3.79 (3.09)	5.39 (2.50)	4.73 (3.34)	3.67 (2.58)
CESD-R[c]: Depression	22.90 (8.30)	23.21 (8.86)	25.50 (8.54)	23.68 (8.58)	21.20 (7.60)
CERQ-Short[d] subscale 1: Self-blame	4.90 (2.70)	5.00 (1.84)	6.04 (2.13)	6.10 (2.13)	4.20 (1.75)
CERQ-Short subscale 2: Acceptance	6.30 (2.24)	5.64 (2.20)	7.39 (2.33)	7.26 (2.37)	7.90 (1.73)
CERQ-Short subscale 3: Focus on Thought/Rumination	5.70 (2.39)	5.07 (1.90)	7.07 (2.16)	6.68 (2.29)	6.00 (1.89)
CERQ-Short subscale 4: Positive Refocusing	5.60 (1.79)	5.21 (2.19)	5.29 (1.90)	5.58 (2.27)	6.40 (2.07)
CERQ-Short subscale 5: Refocus on Planning	7.10 (2.40)	5.86 (2.51)	6.50 (2.23)	6.58 (2.24)	6.10 (2.42)
CERQ-Short subscale 6: Positive Reappraisal	7.40 (2.35)	7.07 (2.30)	8.00 (1.61)	7.68 (1.82)	6.70 (2.47)
CERQ-Short subscale 7: Putting Into Perspective	6.40 (2.39)	5.79 (2.01)	6.43 (2.28)	6.32 (1.60)	5.50 (2.37)
CERQ-Short subscale 8: Catastrophizing	5.50 (2.70)	4.29 (1.07)	6.50 (2.46)	5.89 (2.51)	5.60 (2.41)

[a]CYRM-12: Child and Youth Resilience Measure (12-item).

[b]HSC: Hopelessness Scale for Children.

[c]CESD-R: Centre for Epidemiologic Depression Scale-Revised.

[d]CERQ-Short: Cognitive Emotion Regulation Questionnaire—Short.

Hypothesis One: Youth Who Completed the SPARX Program Were Expected to Experience a Decrease in Depressive Symptoms and Risk Factors Related to Depression, as Measured With the CESD-R, HSC, and CERQ-Short Questionnaires

Participating youth reported feeling less hopeless, and engaged in less self-blame, rumination, and catastrophizing following the SPARX intervention (Table 2). The intervention was a statistically significant predictor of the HSC score (b=–1.08; $t_{51.1}$=–2.17; P=.02<.05; 1-tailed based on the *a priori* hypothesized direction of improvement in health). The intervention decreased the HSC score: Hopelessness by 1 (1.08) unit. The intervention was a statistically significant predictor of the CERQ-Short subscale score 1 (Self-blame; b=–0.86; $t_{53.2}$=–1.95; P=.03<.05; 1-tailed). The intervention tended to decrease the CERQ-Short subscale score 1: Self-blame by close to 1 (0.86) unit. The intervention was a statistically significant predictor of the CERQ-Short subscale score 3 (Focus on Thought/Rumination; b=–0.77; $t_{53.6}$=–1.84; P=.03<.05; 1-tailed). The intervention was a statistically significant predictor of the CERQ-Short subscale score 8 (Catastrophizing; b=–0.90; $t_{52.7}$=–2.00; P=.02<.05; 1-tailed).

For scores on the CESD-R, and the CERQ-Short subscale scores 2, 4, 5, 6, and 7 (Acceptance, Positive Refocusing, Refocus of Planning, Positive Reappraisal, Putting Into Perspective), the intervention indicator variable at the α=.05 level (2-tailed, and where relevant 1-tailed) was not statistically significant.

Table 2. Overview of outcomes following the SPARX intervention (n=22).

Primary outcomes: scale or subscale score	Desirable direction of improvement	Prescore (pooled groups A and B)	Postscore (pooled groups A and B)	Pre to post *t* test (pooled groups A and B)	Repeated measures ANOVA (pooled groups A and B)	Mixed models (multilevel regression models; comparing groups A and B)
CYRM[a]: Resilience	↑	47.389	44.389	Post ↓ (*P*=.02)	Intervention ↓ (*P*=.01)	Intervention ↓ (*P*=.02)
HSC[b]: Hopelessness	↓	4.458	3.667	Post ↓[c] (*P*=.08)[d]	Intervention ↓ (*P*=.01)	Intervention ↓ (*P*=.02)[d]
CESDR[e]: Depression	↓	N/A[f]	N/A	Post ↑ (*P*=.02)	Intervention ↑ (*P*=.01)	Intervention ↑ (*P*=.08)
CERQ-Short[g] subscale 1: Self-blame	↓	5.348	4.609	Post ↓ (*P*=.01)	Intervention ↓ (*P*=.02)	Intervention ↓ (*P*=.03)[d]
CERQ-Short subscale 2: Acceptance	↑	6.238	6.476	Post ↑ (*P*=.03)	Intervention ↓ (*P*=.07)	Intervention ↓ (*P*=.07)
CERQ-Short subscale 3: Focus on Thought/Rumination	↓	6.174	5.478	Post ↓ (*P*=.04)[d]	Intervention ↓ (*P*=.05)	Intervention ↓ (*P*=.04)[d]

Hypothesis Two: Youth Who Completed the SPARX Program Were Expected to Experience an Increase in Factors Related to Resilience

Youth in the study did not show an increase in formal resilience indicators. The CYRM-12 intervention indicator was not statistically significant at the α=.05 level (2-tailed).

Discussion

Principal Findings

Overall, key findings suggest that youth who completed the SPARX trial learned new cognitive emotional regulation strategies to help support them in challenging maladaptive thought patterns. Youth also appeared to experience less hopelessness after engaging in SPARX. No formal indication of a decrease in depressive symptoms or an increase in resilience was noted after engaging in the SPARX program.

Youth who completed the SPARX program were expected to show a decrease in depressive symptoms, which was not evident in this pilot study. However, outcome measures suggest that, for Inuit youth in Nunavut, SPARX may be an effective program for decreasing feelings of hopelessness, as well as the cognitive emotion dysregulation signified by self-blame. Cognitive emotion regulation has consistently been linked to mental health, with those who possess more adaptive regulation strategies better able to cope with stressful or adverse life experiences [31]. Elevated self-blame, rumination, and catastrophizing are 3 factors known to be highly correlated with poor emotion regulation and mental health difficulties, such as depression and anxiety [32]. Youth who tend to ruminate on negative events, catastrophize, and self-blame are more likely to develop depressive symptoms. These youth have increased difficulty inhibiting and regulating their appraisal, which likely leads to more catastrophizing thoughts [33].

Although depressive symptoms on the whole did not decrease after youth trialed SPARX, results suggest a decrease in negative emotion regulation strategies. This is encouraging given the evidence that negative coping styles are associated with greater depressive symptoms [34]. With a reported decrease in self-blame, catastrophizing, and rumination, youth may develop enhanced coping strategies to deal with adverse life events. Hopelessness has been one of the most important mental health factors examined in attempts to understand suicidal behavior and has been linked to suicide in Indigenous populations [35,36]. It is encouraging that results show a decrease in hopelessness and an increase in cognitive emotion regulation strategies. This supports the need to further examine the effectiveness of SPARX on a larger scale as well as more longitudinally, as CBT therapies may be more effective over several months [37].

Youth who completed the SPARX program were expected to experience increased resilience after the intervention but outcome measures provided by youth did not suggest any change in the resilience measure. The small sample size may largely explain this finding. It is also possible that the resilience measure itself was not culturally relevant or appropriate. Despite the lack of significant changes recorded in the formal measures of resilience, there is reason to believe that a decrease in the hopelessness scale may promote and foster greater resilience [36]. It is possible that SPARX may prove to be an effective treatment for decreasing depressive symptoms and boosting resilience when assessed in a larger study.

Youth in Nunavut disproportionately struggle with mental health concerns in comparison to youth in other Canadian territories and provinces. Despite this disparity, Inuit youth lack access to mental health services, largely because of a shortage of staff to provide and assist with evidence-based treatments, a direct result of continued oppression and marginalization under enduring colonialism experienced by these communities [10]. Developing mental health programs that do not necessarily require staff support may be viable options in overcoming this barrier. Extant literature documents the success of computer-based CBT programs in increasing access to mental health resources for youth [38-40]. A review of over 100 studies evaluating the use of e-interventions for children and youth struggling with mental health needs showed that technology-assisted interventions are becoming an increasingly common form of service delivery in Australia, New Zealand, the United States, the United Kingdom, Canada, and the Scandinavian countries [41]. Thus, an increasing number of studies are overwhelmingly supportive of e-interventions, including serious games, as successful therapeutic tools. In addition to their clinical benefit, results suggest enhanced interest in and access to these services by youth, decreased costs compared with traditional services, and greater quality of life for those who access e-interventions [41]. Moreover, a growing field of research is specifically examining the use of these programs in remote and Indigenous communities, with promising results demonstrating the effectiveness of computer-based programs with these populations [38]. Digital interventions have demonstrated success in many remote and underserved communities, as they increase access, break down barriers, and fill key gaps in service provision [41-44].

This study aimed to establish whether SPARX would be an effective intervention for fostering resilience and decreasing the risk of depression with Inuit youth in Northern Canada. It appears as though SPARX may be a good first step for supporting youth with skill development for challenging maladaptive thoughts and providing behavioral management techniques such as deep breathing. Further larger-scale studies are required to understand whether SPARX or similar e-interventions can be effective in decreasing symptoms of depression.

Limitations

We encountered several challenges during the implementation of this pilot study: (1) complications with youth recruitment, which resulted in the adoption of less rigid exclusion criteria; (2) challenges pertaining to the staffing of facilitators; (3) unavoidable deadline extensions due to staffing challenges, technological difficulties, and barriers in communication; and (4) a poorly matched control and intervention group when it came to sample size, duration, and frequency of play for youth in each group. The numerous challenges encountered caused this study to be drawn out over 9 months instead of the proposed 4.

As is common with pilot studies, the statistical power of our analysis was limited by a small sample size. Pilot studies are not expected to provide definitive statistical results, but rather to confer suggestive results for follow-up [45], and despite the lack of power we can report some statistically significant findings at the α level of .05. In addition, the “play now play later” procedures for this study were intended to control for the effects of fluctuations in mood due to daylight hours and fluctuating temperatures in the North. This was managed by having youth in the control group exposed to SPARX 2 months after youth in the intervention group completed their use. However, a strict deadline had to be set for the end of the study, and thus many youth in the control group were given a shorter time allowance for completing the SPARX program. Differences between the 2 groups in the frequency and duration of their SPARX play undermined the advantages of having a control group. Further, as a result of this deadline, there were fewer youth who participated in the control group. Finally, for ethical reasons, no participating youth were denied access to SPARX (ie, we ensured both group A and group B participants were all eventually given access to the intervention). Without a true control group where some participants did not receive SPARX, it is impossible to rule out confounds in the results. Unmatched sample sizes across the 2 groups, and an overall smaller-than-anticipated sample size, also weakened the scientific rigor of this study.

Another limitation was that the questionnaires used in this study, which were designed and systematized based on Western, Eurocentric concepts of depression, hopelessness, and resilience, did not properly access the experiences and expressions of mental health for Inuit youth in Canada. It is also possible that challenges with English language literacy confounded findings with Inuit youth participants despite staff being available to assist. It is possible that using local dialects (Inuinnaqtun and

Inuktitut) for questionnaires would better support youth's understanding of their mental health difficulties.

Finally, inconsistent access to the internet in most communities meant it was difficult to administer surveys; this also hindered data collection, participation monitoring, and recordkeeping. The high turnover of community facilitators created confusion with frequent changes in their roles and inadequate time provided for training, knowledge mobilization, and relationship development with youth participants. The conditions under which the trial was administered understandably created ambivalence among community facilitators, who were generally in favor of an intervention that might eventually benefit their communities but also struggled with the additional workload it imposed. All of these barriers, including short staff contracts, high staff turnover, youth attrition, inordinate mental health needs, lack of phone and internet access, and communication difficulties, are closely linked to continued colonization practices. Inuit youth in Canada continue to face systemic challenges and resource disparities as a result of poor government funding and a lack of consultation with communities for needs assessment and program development.

With these barriers and limitations in mind, we are also aware that this pilot study is rooted in a positivistic Western framework and was designed, conducted, and facilitated primarily by Qallunaat (non-Inuit). However, due to limited funding, this commissioned study had to be conducted remotely and included directives from the Government of Nunavut to involve local mental health workers, most of whom are not Inuk themselves, to administer the SPARX trial. This exploratory pilot served as a feasibility study fostering enthusiasm and cohesion among participating communities and scaffolding more culturally appropriate research. In a companion study [46], participating youth and community facilitators built much of the knowledge necessary through exit focus groups to facilitate such an endeavor. Indeed, efforts are now well underway to follow-up with a more community-directed and culturally meaningful study focused on articulating Inuit knowledge and research epistemologies through holistic, relational perspectives rooted in *Piliriqatigiinniq*, the Inuit concept for working collaboratively for the common good [20]. We recognize that research in Inuit communities must be collaborative and inclusive, underscoring "the right of colonized, Indigenous peoples to construct knowledge in accordance with the self-determined definitions of what they want to know and how they want to know it" [20](p12).

Future Directions

We present here preliminary findings that suggest that serious games such as SPARX could lead to improvements in emotion regulation and, by association, depressive symptoms; however, conflicting findings suggest youth's mood did not change after SPARX engagement. It will be important to replicate this study on a larger level, including more communities. It may also be beneficial to allow for online play. This will have the added benefit of increased rigor by allowing the research team to directly monitor engagement and frequency and length of play. It will be important to add a true control condition in the next trial to ensure that SPARX's effectiveness can be more conclusively established. In addition, it will be important to gauge what mental health and mental illness mean to Inuit youth in Canada. This will help foster an understanding of more culturally appropriate questionnaires for accessing youth's experiences with SPARX. Finally, using measures that have been validated with Inuit communities in Canada may help ensure that youth can more accurately report their mental health status. With a more culturally appropriate model for understanding Inuit youth mental health symptomology, an assessment of mental health changes attributable to the SPARX program may be more accurate.

Learning from the many barriers encountered here will allow for a more culturally competent and rigorous approach to conducting future research. It will be important to examine these barriers and to address them in any future protocol (such a follow-up study is currently underway). For example, having a community facilitator working specifically on SPARX will better support youth engagement, mitigate attrition, and foster greater trust between the youth and community facilitators. SPARX in schools might synergize well with institutional curricula and help with recruitment, engagement, and the generalizability of skills. Having a researcher on-site in the communities may help with supporting the community facilitator, troubleshooting any technological difficulties, and minimizing communication barriers. These extra supports, and the concomitant potential for more rigorous research with a larger sample size and true control group, will make an effective evaluation of the SPARX program more feasible. Furthermore, it may be advisable to hire a number of youth from each community to promote SPARX, advocate for the program, and help reduce the mental health stigma their communities may be facing.

Finally, it will be imperative to work with youth and communities to design, develop, and test an Inuit version of the SPARX program, tailored to fit the interests of Inuit youth and Elders in Canada and to increase engagement and effectiveness of the program. Such an initiative is underway. Existing studies suggest that incorporating one's culture into an already compelling psychoeducational serious game has the potential to promote cultural esteem and community-based resilience, in addition to fostering individual resilience.

Acknowledgments

We wish to thank the Nunavut Territorial Department of Health for sponsoring this study. We also gratefully acknowledge youth participants and community facilitators for contributing their time, wisdom, and energy to the project.

Conflicts of Interest

The intellectual property for SPARX is held by UniServices at the University of Auckland. Any proceeds from licensing or selling SPARX outside of New Zealand will be shared in part with UniServices, MS, and MFGL (and other co-developers of SPARX who are not coauthors of this article).

Editorial Notice

This randomized study was only retrospectively registered. The authors explained that this is because it was a small, atypical pilot trial. The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials, because the risk of bias appears low and the study was considered a pilot trial. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: Major depressive disorder (MDD) is the leading cause of global disability; however, the existing treatments do not always address cognitive dysfunction—a core feature of MDD. Immersive virtual reality (VR) has emerged as a promising modality to enhance the real-world effectiveness of cognitive remediation.

Objective: This study aimed to develop the first prototype VR cognitive remediation program for MDD ("bWell-D"). This study gathered qualitative data from end users early in the design process to enhance its efficacy and feasibility in clinical settings.

Methods: Semistructured end-user interviews were conducted remotely (n=15 patients and n=12 clinicians), assessing the participants' perceptions and goals for a VR cognitive remediation program. Video samples of bWell-D were also shared to obtain feedback regarding the program. The interviews were transcribed, coded, and analyzed via thematic analysis.

Results: End users showed an optimistic outlook toward VR as a treatment modality, and perceived it as a novel approach with the potential of having multiple applications. The participants expressed a need for an engaging VR treatment that included realistic and multisensorial settings and activities, as well as customizable features. Some skepticism regarding its effectiveness was also reported, especially when the real-world applications of the practiced skills were not made explicit, as well as some concerns regarding equipment accessibility. A home-based or hybrid (ie, home and clinic) treatment modality was preferred.

Conclusions: Patients and clinicians considered bWell-D interesting, acceptable, and potentially feasible, and provided suggestions to enhance its real-world applicability. The inclusion of end-user feedback is encouraged when developing future VR programs for clinical purposes.

Introduction

The Socioeconomic Impacts of Depression

Major depressive disorder (MDD) affects approximately 5.4% of the Canadian population [1]. Most recently, the COVID-19 pandemic has increased the proportion of Canadians experiencing depression. Among people aged 25 to 44 years, the proportion of people with MDD increased from 18% in fall 2020 to 23% in spring 2021 [2]. MDD is the leading cause of disability worldwide, substantially affecting psychosocial, occupational, and academic functioning [3]. MDD costs the Canadian economy approximately >CAD $30 billion (US $22 billion) annually in reduced workplace productivity [4]. MDD also affects academic performance in young adults. University students are at higher risk of depression than general population, resulting in lower grade point averages, lower academic performance satisfaction, and higher dropout risk [5-7].

Current treatments, although effective in improving core symptoms of MDD, fall short in addressing MDD-related disability [8-10]. Symptomatic improvements are not necessarily accompanied by restoration of occupational and psychosocial functioning—patients who are diagnosed with mild or remitted depressive symptoms may still show occupational and academic disability [9,10]. Accordingly, treatment priorities have shifted to targeting functional recovery, rather than solely symptomatic remission [8,11,12]. There has been increased interest in expanding mental health services in university campuses, as well as workplace mental health programs to identify and treat employees with depression [13]. While such programs can be helpful in reducing depression symptom severity, they neither necessarily result in major improvements in workplace or academic productivity, nor in decreases in presenteeism [14-18]. Thus, depression treatment strategies specifically targeting academic and occupational recovery remains an unmet need.

Cognitive Deficits in Depression

To enhance occupational functioning in MDD, cognition is an important intermediate target [19]. Cognitive dysfunction is often found in depressive disorders such as MDD, with deficits in memory, attention, processing speed, and executive functioning detectable in acutely symptomatic and remitted patients [20,21]. Importantly, cognitive functioning has been associated with occupational functioning in acutely depressed and recovered individuals with MDD [22-24]. However, there is a lack of effective treatments for cognitive deficits in depression. Major cognitive impairments may persist in individuals who attain symptomatic response or remission with established depression treatments [20], and antidepressant medications have inconsistent and sometimes negative effects on cognitive functioning [25].

Cognitive remediation has emerged as a promising treatment strategy for addressing cognitive deficits in psychiatric disorders [26,27]. This is a treatment method based on the repeated practice of computer or paper-and-pencil exercises that target specific cognitive skills (eg, sustained attention, verbal memory, and working memory) with the purpose of enhancing patients' work and social functioning abilities [28]. Cognitive remediation has strong evidence for improving cognition and functioning in schizophrenia, as well as showing promise in bipolar disorder and attention-deficit/hyperactivity disorder [26,27,29]. However, these results are less consistent in depression—a recent meta-analysis of cognitive remediation in depressive disorders found moderate effects on attention and working memory, with no major effects on executive functioning or verbal memory [30]. It also remains unclear if the skills practiced during cognitive remediation in depression transfer out of the laboratory environment and result in substantial real-world functional improvements [31-33].

Virtual Reality for the Training of Cognitive Skills

Immersive virtual reality (VR) has attributes which could enhance the delivery of cognitive remediation and has preliminary evidence for efficacy in other neurological and psychiatric disorders [34]. The immersive and interactive nature of VR facilitates greater user engagement and enjoyment compared with computer presented tasks [35,36]. VR also allows for the practice of skills in naturalistic settings, thereby improving the likelihood of skill transfer to the real world [37-39]. Randomized controlled trials have shown that VR-delivered cognitive and vocational remediation results in substantial improvements in cognition and functioning in patients with traumatic brain injury, stroke, schizophrenia, and substance use disorders, even when compared with active control conditions such as therapist administered remediation [40-43]. Additional advantages of using VR technology—which has been growing in mainstream accessibility and decreasing in expense—include its ability to reach a broader range of individuals with minimal cost. In addition, data collected from VR programs can potentially be integrated into digital health services, allowing a highly personalized intervention.

Despite the burgeoning applications of VR technologies and growing use in psychiatric populations, a sustained course of VR cognitive remediation has not been specifically evaluated in depression. As enthusiasm for using VR in clinical settings has grown, so have the questions regarding how to best design VR clinical applications to be usable and efficacious for the target population. A working group of international experts published the first consensus guidelines for best practices in the design and testing of VR clinical applications [44]. In these guidelines, incorporation of qualitative feedback from multiple end users is identified as a critical component of VR program content development. As lack of end-user involvement in development is often at the root of digital intervention failure [45], following best practices in human-centered design is important to enhance the interventions' relevance and effectiveness. Feedback from experts and care providers can ensure that the intervention is based on solid theoretical foundations and is feasible for real-world use.

Building on the existing body of work relating to cognitive remediation in clinical populations, the National Research Council Canada and the University of British Columbia have developed the bWell Cognitive Care Platform for Depression ("bWell-D"), a prototype immersive VR cognitive remediation program for individuals with depression. Following best practices in VR clinical application design, this study collected qualitative data from clinicians and care providers regarding their perceptions and experience with VR, desired outcomes from a cognitive or functional remediation program, and perceived barriers to use of VR cognitive remediation in clinical settings. Later, participants provided their thoughts and opinions specifically regarding the bWell-D program. This information was used to guide program and protocol refinements to bWell-D to boost clinical efficacy and feasibility.

Methods

Ethics Approval

This research was reviewed and approved by the Behavioural Research Ethics Board of the University of British Columbia (Behavioural Research Ethics Board numbers H21-00028 and H20-00746). It was also approved by the Research Ethics Board of the National Research Council Canada (NRC 2020-122).

Participants

Patients

A sample of 15 patients who self-reported a diagnosis of depression were recruited to participate in this study. Recruitment was carried out on the web through the Vancouver Coastal Health Research Institute and REACH BC websites, as well as on a classified advertisements website. Interested participants were screened to ensure they met the eligibility criteria:

1. Aged 18 to 65 years

2. Self-reported diagnosis of previous or current major depressive episodes

3. Self-reported subjective cognitive or functional deficits at baseline, as indicated by a battery of self-report questionnaires. All participants were included in the analysis, regardless of their scores in the clinical measures.

4. Engaged in full-time employment (currently or in the past), with self-reported ongoing functional deficits resulting from depressive symptoms, or off work or on reduced hours with depressive symptoms reported as the primary reason.

5. Sufficient proficiency in English to complete the questionnaires and interview

Patients who were eligible and completed the entire process were compensated for their participation with CAD $20 (US $14.55).

Clinicians

A convenience sample of 12 clinicians participated, with recruitment occurring through the Vancouver Coastal Health Research Institute and REACH BC websites, as well as physical posters displayed on-site at relevant health units. Clinicians were also contacted through the researchers' professional contacts. Interested clinicians were provided a letter of invitation and confirmed their interest in participating via email. Clinicians must have been allied health professionals (eg, psychiatrists, psychologists, family physicians, occupational therapists, or nurses) with experience working with populations with depression, and experience with cognitive or functional remediation in psychiatric populations. Clinicians were not offered a monetary compensation.

Procedure

This study was conducted remotely through videoconferencing. Participants attended an approximately 1-hour Zoom interview, in which they were first explained the purposes of the study, and oral informed consent were obtained. Participants then completed a web-based Qualtrics survey asking for demographic data. In addition, patients completed a series of psychiatric and psychological questionnaires (see the *Measures* section), whereas clinicians answered questions related to their clinical practice. After completing the questionnaires, a semistructured interview was conducted, in which participants were asked regarding their perceptions and experiences with VR, their desired outcomes from a workplace cognitive or functional remediation program (bWell-D), and perceived barriers to use this type of treatment in a clinical setting. Participants were then shown previously recorded video samples of the bWell-D tasks and were asked to provide their thoughts on them, their potential relevance to daily life, and suggestions on how to improve the tasks to enhance engagement and real-world applicability (see Multimedia Appendix 1 for the interview scripts).

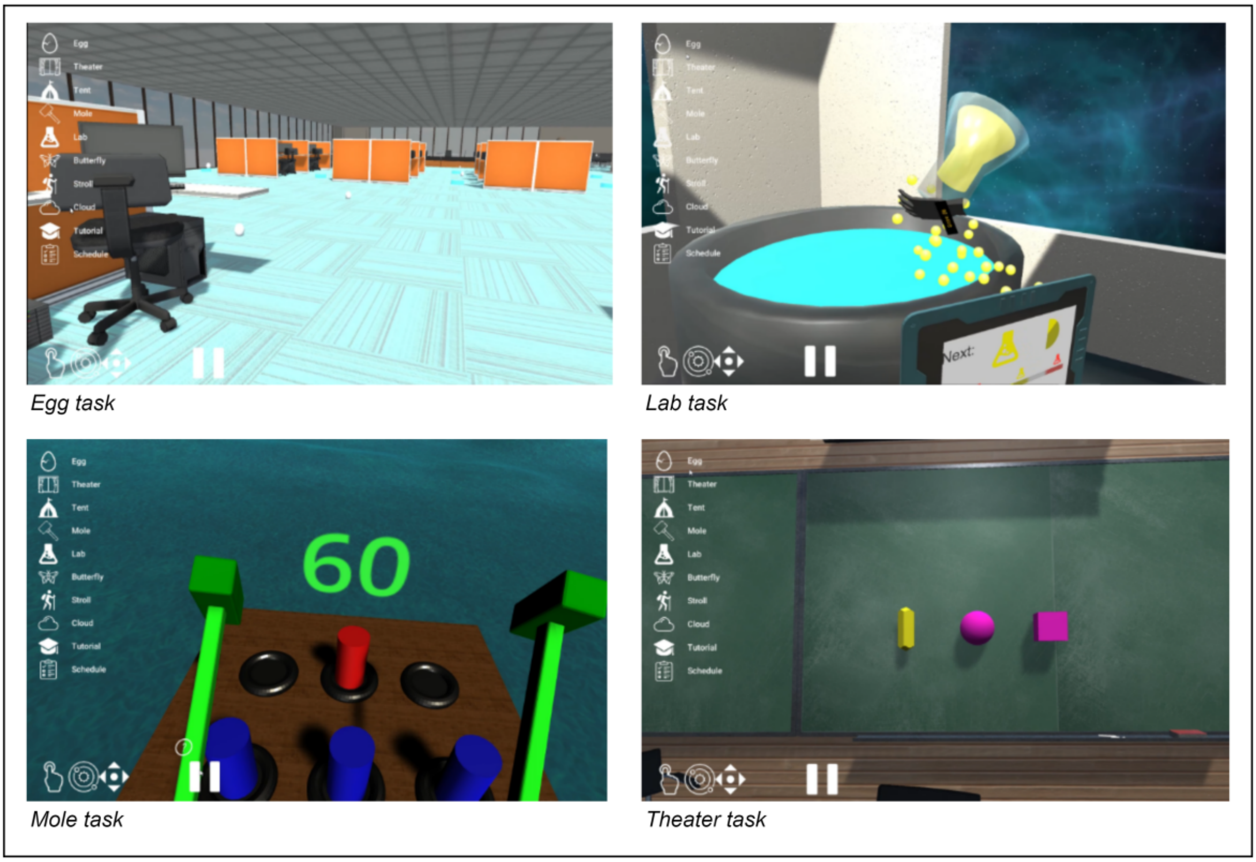
The bWell-D Program

Overview

"bWell-D" is a prototype of immersive VR cognitive remediation program for depression, developed by a collaboration between the University of British Columbia and the National Research Council Canada. The foundational platform, bWell, was developed within a network of researchers and clinicians across Canada, features configurable exercises and design as a broadly applicable toolkit targeting general aspects of cognition commonly affected across many disorders [46]. Preliminary acceptability studies in healthy individuals indicate that the platform is enjoyable, engaging, and well tolerated [35,47].

bWell-D is a customized version of bWell, targeting cognitive and real-world challenges germane to MDD depression [20,21,46]. Two bWell tasks were modified to include real-world environments, that is, the (1) office and (2) classroom. It additionally uses previously identified common components of successful cognitive remediation in psychiatric populations. These include (1) "errorless learning," wherein participants are provided support in learning all task components, with supports gradually removed as skills and confidence increase and (2) "adaptivity," in which tasks become increasingly complex to match with the participant's competence [31]. bWell-D involves 4 different tasks (Figure 1) that aim to train cognitive skills that are commonly affected in MDD. Participants can interact with the virtual environment through a headset and 2 hand controllers.

Figure 1. Screenshots of the bWell-D tasks.



Egg (Attention)

In this task, the patient is asked to look around in an office environment and look for eggs. Once locating the egg with their sight, they are required to fix their gaze on the egg until it hatches.

Lab (Multitasking)

Participants must complete 2 recipes simultaneously by pouring multicolored flasks into 2 mixing bowls. The recipes will appear in 2 tablets placed nearby, and participants will have to go back and forth between recipes.

Mole (Reaction Time and Response Inhibition)

Following similar rules to the whack-a-mole game, participants hold a hammer in each hand and hit the cylinders that pop out of a table. The cylinders are multicolored, and the colors of the hammers also change over time. Participants are asked to hit the cylinder that matches the hammer's color.

Theater (Visual Working Memory)

The participants are shown a sequence of shapes that will be hidden after a set viewing time. A pool of objects will then be presented to the participant, from which they must choose the shapes that were initially shown to them and recreate the original sequence.

The bWell-D tasks operate in three modes: (1) tutorial, (2) assessment, and (3) training. Tutorial has the aim of familiarizing the patient with the virtual environment and showing them the actions they must perform in the tasks. Assessment mode has the purpose of identifying the patients' individual needs by assessing their task performance with a fixed difficulty level. In the training mode, the level of difficulty is adaptable based on the patients' performance. Real-time feedback is provided to the patient, showing them level or score changes and successes and errors.

Measures

Along with the demographic questions included in the Qualtrics questionnaire, patients also responded to the following psychiatric and psychological measures:

Lam Employment Absence and Productivity Scale

The Lam Employment Absence Productivity Scale [48] is a work functioning and productivity scale to be used specifically with patients with depression. It is a 10-item scale, in which the first 3 questions are open-ended and ask regarding the patients' type of work, the number of working hours scheduled in the past 2 weeks, and the number of working hours missed in those 2 weeks. The following items are rated on a 5-point Likert scale ("None of the time" to "All the time"), scored as 0 to 4. Work impairment rating can range between "None to minimal" to "Very severe."

Generalized Anxiety Disorder–7 Items

The Generalized Anxiety Disorder–7 items [49] is a short measure of anxiety. Participants are asked how often they have been bothered by their anxiety symptoms during the past 2 weeks. The measure follows a 5-point Likert format, ranging from "not at all" (0) to "nearly every day" (4).

Sheehan Disability Scale

The Sheehan Disability Scale [50] is a short measure of disability and functional impairment. The first 3 questions are in a Likert scale format, inquiring regarding the severity of cognitive symptoms affecting the patients' work and social and family life from "not at all" (0) to "extremely" (10). The last 2 open-ended questions ask regarding the patients' missed days at work, and regarding the days when the patient felt underproductive.

Perceived Deficits Questionnaire–Depression

The Perceived Deficits Questionnaire–Depression [51] is a 20-item questionnaire that assesses subjective cognitive dysfunction in people with depression in the past 7 days. It follows a 5-point Likert scale, with response options ranging from "Never" (0) to "Almost always" (4).

Beck Depression Inventory

The Beck Depression Inventory [52] is a 21-question, self-report Likert scale that measures the severity of depression symptoms. Responses range from 0 to 4, in which a higher number indicates a more pronounced symptom severity.

Cognitive Failures Questionnaire

The Cognitive Failures Questionnaire [53] is a measure of self-reported failures in perception, memory, and motor function over the past 6 months. It is a Likert scale consisting of 25 items ranging from "Never" (0) to "Very often" (4).

Qualitative Data Analysis

Interviews were recorded and transcribed verbatim. The transcriptions were made with Otter.ai, a web-based service that uses artificial intelligence to transcribe audio recordings. The transcriptions were reviewed and corrected by hand after being processed by Otter.ai. The initial 5 interviews (3 clinician interviews and 2 patient interviews) were coded by the first author to identify an emerging thematic framework [54]. Coding was conducted separately for the clinician and patient groups. However, members of the research team (EM, TC, and MEHH) discussed and identified emerging patterns in the data and determined that the coding framework between the 2 groups was similar; therefore, it was decided to analyze the 2 groups together. Subsequent transcripts were coanalyzed and discussed based on the initial thematic framework. Thus, the data analysis began with the delivery of the first interview and proceeded concurrently and iteratively. The NVivo (QSR International) software was used to aid with the coding and thematic analysis process.

Results

Participant Characteristics

Patients

Participants were aged between 21 and 63 years, with a median age of 31 (mean 34.2, SD 11.5) years. Most participants self-identified as women (n=10), with 3 as men and 2 as nonbinary. The most common diagnosis was MDD (n=8), and 1 patient was diagnosed with dysthymia, 1 with bipolar disorder, 4 of them reported being diagnosed with depression but did not remember the specific diagnosis, and 1 did not have a formal depression diagnosis, but manifested having all the clinical symptoms for it (this was later confirmed at the screening stage). Patients with a formal diagnosis reported being diagnosed between 3 and 16 years ago. At the time of the interview, none of the patient participants were undertaking any psychological treatment, however, 4 of them were taking medication to treat their depression symptoms.

Patients' clinical scores are provided in Table 1. Overall, participants surpassed the threshold for a clinical diagnosis in all measures. All participants reported having their work or academic performance affected by their depression symptoms, and all of them have had to take some time off work or school, ranging from a few sporadic days, to several years. Participants stated working only approximately 80% of their scheduled work hours, some of them having to quit work completely because of the severity of their depression symptoms. Furthermore, 9 patients were either currently employed or studying, while 6 of them were unemployed and identified depression as one of the main causes for their unemployment. From the participants who were employed at the time of the interview, 4 had administrative jobs, 3 had professional jobs, and 2 worked in sales.

Table 1. Patients' clinical measures.

Measures	Values, n	Values, median (range)	Severity[a]
LEAPS[b,c]	9	15 (4-29)	Moderate
GAD-7[d]	15	19 (9-27)	Severe
SDS[e]	15	22 (6-30)	Markedly impaired
PDQ-D[f]	15	46 (7-69)	Risk range
BDP[g]	15	25 (8-47)	Moderate depression
CFQ[h]	15	62 (15-79)	Above average cognitive complaints

[a]On the basis of median scores.

[b]The LEAPS is only for participants who are currently engaged in paid employment, hence the reduced sample who responded to this specific measure.

[c]LEAPS: Lam Employment Absence and Productivity Scale.

[d]GAD-7: Generalized Anxiety Disorder–7 items.

[e]SDS: Sheehan Disability Scale.

[f]PDQ-D: Perceived Deficits Questionnaire–Depression.

[g]BDP: Beck Depression Inventory.

[h]CFQ: Cognitive Failures Questionnaire.

According to the open-ended questions in the Lam Employment Absence Productivity Scale, employed participants had between 50 and 80 scheduled work hours in the previous 2 weeks, and although most of them worked their full shifts, 2 participants only worked between 15 and 20 hours. Four participants were currently working reduced hours, and they have been in this work modality between 2 months and 1 year. The responses to the open-ended questions of the Sheehan Disability Scale indicated that employed participants had lost between 1 and 20 days of work in the past month because of their depression symptoms. Even when attending work or school, participants reported that depression affected their performance in the last month, ranging from 30% of the days to 50% of the days. One participant reported feeling these effects daily.

Clinicians

Participants self-identified as 5 women and 7 men. There were 7 psychiatrists, 2 occupational therapists, 1 psychologist, 1 clinical counselor, and 1 neuropsychologist. They had varied years of experience as mental health practitioners, ranging from 2 to 50 years, with a median of 17.5 years. Five clinicians reported having <5 years of experience in clinical practice, while 6 of them reported having >20. One clinician reported having between 5 and 10 years of experience.

Most of the clinicians worked in an outpatient setting (n=10), either at hospital clinics or private practice. Only 1 clinician worked at an inpatient psychiatric hospital, and another one worked at a community health center. In total, 7 clinicians provided a consultation and assessment and short-term follow-up model of care, 3 of them offered long-term follow-up, and 2 of them did single consultation and assessment with no follow-up. Furthermore, 4 clinicians offered primarily pharmacological and medication treatment modality, 3 of them offered primarily psychotherapy, 3 of them a combination of medication and psychotherapy, and 2 focused primarily in functional rehabilitation. Clinicians who provided psychotherapy offered behavioral treatments, such as cognitive behavioral therapy, dialectical behavior therapy, and acceptance and commitment therapy.

A total of 7 clinicians estimated <50% of their patients had a depressive disorder, while the remaining 5 estimated that more of the 50% of their patients had depression. Five clinicians had experience with cognitive or functional remediation, and they had between 0.5 and 5 years of experience with this type of treatment. Most clinicians (n=9) had been working remotely because the start of the COVID-19 pandemic, mostly relying on videocalls, phone calls, and (less commonly) computer tasks with their patients.

Thematic Analysis

Overview

Participants held mostly positive opinions regarding bWell-D, considering it an entertaining and safe treatment modality. Five themes were identified during the thematic analysis, specifically participants' previous knowledge regarding VR technology, its potential for clinical uses, a desire for realistic settings and situations, the entertaining features of VR, and the need for an inclusive treatment. A description of each theme and representative quotes are presented below.

Familiarity and Optimism: Openness to Trying VR for Mental Health Symptoms

Both patients and clinicians had at least some degree of familiarity with VR. Patients were familiar with VR mostly from videogames and movies, while clinicians were also aware of its use for clinical purposes, especially for anxiety-related conditions, psychosis, and brain injury. When participants did not have direct experience with VR, they mentioned hearing good things regarding it. Participants with little or no exposure to the technology spoke of their curiosity regarding trying it.

> *I mean, I'm curious to see if it could, in any way, help my own mental health issues. And, I don't know, it's something I haven't tried yet. And I'm open to trying things that might improve my wellness.* [Patient 003; woman; 43 years]

> *I don't really know too much about it. But I'm very open to learning more. I guess, like I don't know enough to say whether I see potential or not, so I'm eager to learn more.* [Clinician 005; woman; occupational therapist]

Participants with a higher exposure to VR, and the ones who enjoyed videogames, were the ones who showed higher enthusiasm regarding this technology.

VR as a Potential but Underexplored Treatment Option for Cognitive and Functional Deficits in Depression

Although both patients and clinicians often considered mood symptoms as the most salient symptom in depression, they acknowledged that cognitive symptoms are also affected. They described cognitive issues as particularly harmful for work life, because they have a direct effect on job performance, which can in turn exacerbate feelings of shame and stigma:

> *It was just a really hard time. I just, I couldn't concentrate, well, I still have a hard time concentrating. Just my, my work ethics went down. I don't know, everything became really hard. I missed a few days here and there, like I felt, but at the same time, like even though I was told by the doctors like, 'No, you need to take time off,' I kept going because I didn't want to be judged behind my back. But if anything that made it worse [...] But I know that my, my work has gone down, like, and I have a really hard time concentrating.* [Patient 001; woman; 21 years]

Several patients considered that training their cognitive skills through VR can help them not only for work purposes but also with their day-to-day life:

> *I go into a room to get band aids, I forget what I'm in there for, literally my house is not that big. And I go back in the living room wondering what the hell I was looking for. So it, I feel like it would help with work and with my personal life, which is just a double bonus.* [Patient 003; woman; 43 years]

They were confident that their cognitive abilities can be re-established after experiencing depression. When asked regarding the potential applications of VR for depression, 2 clinicians and half of the patient sample struggled to see how this technology could be used for this condition:

> *I'm aware of the promise of virtual reality treatments for anxiety disorders and things like that. I would be, I don't see the application to depression or bipolar disorder. So you know, in that end, those are the two disorders I treat the most. So therefore, I'm not particularly looking at this. And I'm surprised to hear about a virtual reality treatment for depression* [Clinician 009; man; psychiatrist]

Participants considered VR a safe alternative to conventional psychiatric treatments, and most patients were willing to try it because of its perceived lack of serious side effects. Participants believed that more effective treatments for mood disorders are needed, and therefore, VR can be a promising alternative.

> *I don't always enjoy the medication approach, like the side effects can be quite frustrating at times. So I think something without, like, a less medicalized approach could be really helpful. And you could avoid some of the negative side effects.* [Patient 014; woman; 21 years]

> *I think we need all the treatments we can get for mood disorders. So I'm curious.* [Clinician 009; man; psychiatrist]

Participants believed that VR is a novel approach to treat depression, and because it is becoming increasingly popular for clinical purposes, they would like to explore this treatment modality further:

> *I think will become more common in the future. So I think it might be like a good way to look into it and learn about it before it like the, as is, you know, gaining more popularity.* [Clinician 005; woman; occupational therapist]

A few participants, however, considered this "newness" a limitation to start using VR, because it is not standard practice in most health care institutions:

> *I practice in a large university hospital type setting. The university hospital always is incredibly bureaucratic, and never wants anything that's innovative or different. They only want things that are standard. So anytime you try to introduce something new, it's very challenging. So I would say that it would be unlikely that even if this treatment were approved tomorrow by Health Canada or the FDA, I would say it's very unlikely that our system would use it for anytime in the next few years.* [Clinician 009; man; psychiatrist]

Despite the general enthusiasm regarding using VR and cognitive remediation, both patients and clinicians had some further reservations, and mentioned needing more evidence before undertaking a treatment of this nature. Most clinicians mentioned that, although this type of treatment has shown promising results in some conditions, they would like to have more evidence for its specific use in depression. They would like to obtain this information from methodologically sound research studies:

> *If there is going to be evidence for that, for the type of patients that I've seen, and the patients are willing to participate? So yeah, for sure [...] It's not part of the kind of the regular practice, or part of the standard guidelines. But once the evidence is there, for sure.* [Clinician 012; man; psychiatrist]

Furthermore, approximately half of the patient sample mentioned that the VR format might not have any particular advantages over other modalities of cognitive remediation delivery:

> *I think the only like, pushback that might be received is like, what is the difference between doing this and playing like, a task related like, video game, I guess? Like, I think that there's an, there's maybe an opportunity for, like, people who are depressed to be like, "Well, if I if I'm basically just going to a lab to play a game, what's the difference between me doing that, and me just like downloading a game on my phone where you're being asked to, like, do memory parts?"* [Patient 008; woman; 30 years]

Desire for Ecologic Validity

Several patients mentioned that they would like to understand exactly how the tasks practiced in bWell-D work, so they do not feel like they are "just playing a game." They also mentioned needing an explanation regarding how to extrapolate the trained skills to their real-life world:

> *My honest opinion on the games, they all seem like kid games. They all seem very simple and straightforward, but simple animation. And I find like, I might think it's just a silly game, but I think once I start actually playing them, I would realize how it's helping.* [Patient 007; woman; 28 years]

> *I think I would need the therapist to, like, fully explain what this was training and helping with, because, like, the one thing that triggered me when I was in a depressive state was that, like, I knew I was smart, but then like, when I was in a depression, I wasn't functioning, that, like, as normal, and then I would feel really, really dumb. And like, seeing this kind of activity makes me feel like, you know, it gives a reaction like, I'm not a child, like, why am I putting shapes together?* [Patient 10; woman; 27 years]

Most participants mentioned that VR offers the possibility of immersing themselves in settings and situations that resemble real life in a highly accurate manner:

> *It's very interesting in the way that all new technology is very interesting. And it's remarkable, you know, the sense of presence when you're in the VR environment. It, you know, unless you've experienced it, it's hard to imagine, you know, it's very much like being in the real world.* [Clinician 011; man; psychiatrist]

Most patients mentioned they would like the virtual environments to look like their own work or school setting, as well as including objects (eg, office supplies or school furniture) and situations (eg, conversations with colleagues, following instructions given by their boss or teacher) that emulate real life (eg, interactions with humans and distractions). They believed that these naturalistic aspects can enhance skill extrapolation:

> *I think that it would also require some effort relevant to their daily activities, or have some translational component.* [Clinician 004; man; psychiatrist]

> *I think if I work in an office, it would, it would be better because I'd be able to take what I'm doing within that virtual reality, and apply it more to the environment that I'm hoping to improve my concentration in. But because it doesn't look like where I work it's difficult to connect the two.* [Patient 007; woman; 27 years]

Participants considered VR as "the second-best thing to real life," because it allows an immersion in highly realistic environments. Participants desired to obtain this realism through several ways, (1) by having virtual settings that emulated patients' own real-life environments, (2) by including distractors in the VR world that would occur in real life, and (to a lesser extent) (3) by having realistic-looking graphics. Patients and clinicians also stated that VR environments allow for the practice of skills and exercises in a more controlled and less intimidating setting:

> *If I were able, was able to get better at that, and because it's a low stress environment in the game, maybe having it, having that experience in a low stress situation would help me in my more stressful situations.* [Patient 014; woman; 21 years]

> *It's like the traditional thing when you, when you're nervous about speaking in front of a crowd is that, you like, you practice your speech in the mirror. It could be something similar to that but in a VR setting, with there being more of a...I don't quite know how to articulate it, exactly.* [Patient 005; nonbinary; 25 years]

A few patient participants mentioned that VR can allow them to focus on only training their skills without getting sidetracked. However, they emphasized the need for improving their cognitive symptoms overall, rather than just improving their performance in the virtual tasks:

> *I'm skeptical because of the literature that's behind this, because there's a lot of evidence saying that you only get better at the game instead of the skill itself, or the cognitive aspect that you're focusing on itself.* [Patient 001; woman; 21 years]

Three clinicians mentioned the importance of ensuring that the skills practiced in programs like bWell-D are actually training what they intend to train, and that the tasks are representative of the actual cognitive processes that patients must perform at their work or day-to-day life:

> *If there's evidence that depressed people have trouble on that sort of task, it makes sense. If you're pulling it out of thin air, because they have trouble on an attempt and inhibition task that's not like that one, then you better rethink how close that task mimics the process you're interested in.* [Clinician 011; man; psychiatrist]

Approximately a quarter of the participants were concerned regarding the long-term effectiveness of the treatment. To address this, a patient suggested having a lengthier VR cognitive remediation treatment, whereas a clinician suggested adding booster sessions. Several participants expressed a desire to obtain treatment progress data through a reliable instrument. Although a few of participants mentioned wanting improved graphics in bWell-D (more realistic looking), others mentioned that this is not too important if the content of the tasks is well designed, and the objects are clear to see. Most participants mentioned that any possible glitches and malfunctions should be minimal or nonexistent for the treatment to be effective and enjoyable.

A Fun and Engaging Treatment: The Advantages of a Digital Environment

Most participants mentioned that the gamified experience of VR adds fun, engaging, and immersive elements to the treatment. A need for multisensory stimuli (ie, tasks that incorporated auditory and visual components) was mentioned by most of the participants and was considered key for the immersion and involvement in the virtual tasks. Participants also stressed the importance of having a difficulty progression in the tasks, to enhance the challenging aspect of the treatment (without it turning so difficult that it becomes discouraging). A clinician mentioned how this difficulty progression can provide a sense of accomplishment for patients:

> *It definitely gives you kind of that drive, while at the same time being complicated and interesting enough to keep your attention wanting to keep going [...] – I found that one was always a really fun task, a difficult task. Not difficult, but it required enough energy without being overwhelming.* [Patient 015; woman; 33 years]

Most clinicians and patients stressed the importance of having a simple, user-friendly VR interface that included some training period and clear instructions to practice the tasks. A few clinicians considered important to assess patients' satisfaction with the program session to session.

Several participants, especially clinicians, found the versatility of VR to be beneficial for the treatment. They noted that the flexibility provided by VR allows a wide variety of virtual settings, going beyond what is achievable in real life:

> *I think you can help us create a very realistic environment to do some therapeutic work in and potentially make some progress that we haven't been able to outside.* [Clinician 007; woman; psychologist]

A few participants considered a treatment, such as bWell-D less emotionally draining treatment modality than medications or talking therapy:

> *When I was watching it, it occurred to me it's kind of nice to have these videos not relating to real life experiences, and things that are supposed to be kind of fun, because it doesn't feel like you're doing work, even though you are. And that is, at least for me, isn't as emotionally or cognitively draining.* [Patient 015; woman; 33 years]

Seven participants (both patients and clinicians) mentioned that the game-like setting of VR also allows for progress tracking (eg, score and level changes and improvements), either from the beginning to the end of a session, or from session to session.

One Size Does Not Fit All: The Need for Inclusivity and Customizability

Most patients and clinicians mentioned that they would like to have some agency in the manner the VR treatment is conducted. One of the most recurring comments among patients and clinicians was a preference for the patient to have the treatment individually at home, either partially or completely. Participants believe this modality provides a sense of comfort and control:

> *It seems like a nice way to do it yourself. Like, in your own time in, in quiet, in a quiet environment and not have to go anywhere.* [Patient 002; woman; 36 years]

> *I think it would be helpful for people who can't get there, like remotely. Like, there are days when I can't like, get out of bed or like, get overwhelmed by taking the bus, and like, that might be super helpful to be able to join in like that.* [Patient 10; woman; 27 years]

However, a few patients and clinicians believed a treatment of this nature would be better performed at a clinic. In particular, patients with limited space, or with suboptimal conditions to carry out the treatment at home, would like to have the option to do it at a clinic if necessary:

> *If I had to use it at my own home, that would be almost impossible with three kids and, I think, life.* [Patient 012; womana; 42 years]

Participants mentioned wanting a person involved in the treatment even if they choose to do it remotely. Several patients stated that the involved person should be a well-trained facilitator who they trusted. Most of the patients and clinicians mentioned they would like to engage in a VR treatment when mood symptoms and other potential comorbidities are under control, and therefore had enough motivation to undertake the treatment:

> *It depends on the severity, so I think it could be quite hard for some individuals to sustain, you know, attention or memory, if they're having more severe symptoms. But I think as a symptom, sort of subside or set, you know, it's more mild to moderate, we might be able to focus a bit more and pay attention to it a bit better.* [Clinician 007; woman; psychologist]

> *I think like when you are depressed, like, it'd be really hard [...] if there's any sort of resistance in that process. I think like, a really anxious person or really depressed person would be like, 'Nope, I can't deal with it. It's not working. I'm done with it. Not going to use it today' sort of mentality.* [Patient 008; woman; 30 years]

In fact, several patients and a few clinicians mentioned the usefulness of including an activity in bWell-D that specifically targeted mood. After looking at the task video samples, 4 patients also mentioned that some tasks could be more useful than others (eg, patient not currently struggling with memory issues or wanting to focus more on multitasking). Therefore, they would like to tailor the treatment according to their own cognitive struggles and needs. A clinician also commented that, although the office or school-like VR settings could be useful to emulate naturalistic settings, these settings can trigger emotional responses from some people:

> *For people who are not working, many people with depression are on short or long term disability from work, I was just wondering if seeing the office environment might trigger something.* [Clinician 010; woman; psychologist]

Despite the overall positive perceptions regarding bWell-D, approximately half of the clinician sample and one patient stated they would like to do a VR treatment in parallel with other conventional depression treatments (eg, medications or psychotherapy):

> *You target that symptom, but then you work with the clinician long term to, to use this as sort of one of the other interventions that you're using, and I would see this not being a single intervention being used. I see this being used in combination.* [Patient 001; woman, 21 years]

Another of the most mentioned topics among patients and clinicians was how age could be an important factor when undertaking a VR cognitive remediation treatment. In particular, participants believed that the more technologically savvy individuals (often the younger generations) would like the treatment better. In turn, participants believed that older patients might need more coaching and adjustment time to become used to bWell-D. Several participants also believed that people prone to sensorial issues might dislike a VR treatment, because it can make them feel physically ill:

> *The other problem with all of this is that people go into their depression with some of them, depression of course worsens all of this, it can worsen this, but some people have pre-existing audio processing difficulties or visual processing difficulties either genetically or by head injury or a stroke or medical injuries, etc..* [Clinician 002; man; psychiatrist]

Participants also mentioned that the treatment should be accommodating to people from different backgrounds and with different needs, such as people with color blindness or visual impairments, people whose English is their second language, and people with limited mobility. One of the most common concerns was the actual access to the bWell-D program and the necessary equipment (eg, headset, controllers, or computer). Most participants acknowledged that these technological devices, although they are becoming cheaper with time, may still be inaccessible for people with more limited economical resources:

> *They [VR sets] cost a little bit of money, and most people with mental illness don't have any money. So yeah, just having access to it, having access to a headset* [Patient 004; man; 49 years]

> *The job that I work, I don't have coverage yet, and when I do get coverage, I don't know how much it is. And maybe, I'm not sure if the city offers it, like if it's readily available. So I guess cost and availability would be the biggest challenges for that.* [Patient 007; woman; 28 years]

However, a clinician mentioned that, if the treatment shows to be effective for patients, then every effort should be made to open access to it.

Changes Made to bWell-D After Qualitative Feedback

Following the guidelines proposed by Birckhead et al [44], the changes suggested by end users to improve the bWell-D program were discussed among the research team, translated into representative software functionalities during team brainstorming sessions, and were given priority for implementation based on (1) how frequently these changes were suggested by end users and (2) whether these changes were feasible for development in a VR environment. The main areas of improvement suggested by both clinicians and patients were based on the thematic analysis, and mainly centered in (1) taking greater advantage of the potential of VR to create more multisensorial tasks; (2) the inclusion of more ecologically valid VR elements (to reflect more realistic VR environments), as well as having bridging exercises to relate the skills trained in bWell-D to real-world situations; and (3) providing sufficient challenge for fun and engaging tasks. In addition, end users suggested having a user-friendly interface and tutorials to have an opportunity to practice the tasks, which they considered especially important for an at-home treatment. Moreover, participants recommended to include an additional VR activity that specifically targets their mood. Participants believed that these modifications could make bWell-D more interesting, engaging and useful to improve cognitive deficits. The implemented functionalities are described in Multimedia Appendix 2, while Multimedia Appendix 3 provides a more in-depth description of these changes, and Multimedia Appendix 4 shows some visual examples.

Although efforts were made to cover as many of the suggested changes as possible to bWell-D, there were some areas that the research team determined to address with alternative strategies. In particular, one of the suggestions made by several participants was the addition of more VR environments that better emulated patients' real-life settings, such as their own workplace or school. However, the research team concluded that the addition of these VR environments would be too demanding in terms of resources required for software development. Instead, it was decided that such need would be addressed trough bridging exercises, which are clinician-led discussions that help cognitive remediation participants to apply what is trained in the tasks to everyday life [55].

As part of the iterative process in the design of bWell-D, the changes made to bWell-D were later shown to a subset of 4 patient participants, once more as prerecorded video samples. After looking at the updated version of the program, participants were provided with additional information regarding bWell-D and were asked regarding their general opinions regarding the implemented changes (see Multimedia Appendix 5 for the reinterview script). All the participants reacted positively to the changes, and considered them an improvement to the initial version of the program.

Discussion

Principal Findings

The main aim of this study was to explore the opinions of patients and clinicians regarding the use of VR for the treatment of depression-related cognitive disfunction. bWell-D, a VR treatment specifically designed for treating cognitive symptoms of depression, was used as the main VR treatment example for the participants. The results indicate that VR interventions for treating depression and its cognitive symptoms are generally accepted by both patients and clinicians. In the particular case of bWell-D, they considered it an innovative and fun alternative for the treatment of mental health issues. Some suggestions were made for the improvement of bWell-D, such as including multisensorial tasks, cues, and distractors, a progression in the difficulty of the tasks, realistic virtual settings and activities, having a user-friendly interface, including tutorials and an opportunity to practice the tasks before initiating the treatment, and adding a task or VR activity that targets patients' emotional state.

Although the general perceptions regarding VR for clinical purposes and bWell-D were mostly positive, participants also expressed some reservations. In particular, clinicians needed more evidence before implementing a treatment of this nature in their own clinical practice. Although there is a growing body of evidence supporting cognitive remediation [56] and VR in health care settings [57], structural obstacles within health institutions, as well as health professionals' own personal preferences (ie, an inclination for more traditional therapeutic approaches), can prevent them from being open to use strategies or technologies that deviate from their usual practice. This phenomenon has been previously described as resistance to change [58], and it is one of the main reasons why novel approaches in the treatment of several conditions remain underused [59].

Similarly, patients mentioned wanting a thorough explanation regarding how the skills trained in programs such as bWell-D can extrapolate to the real world. To this end, psychoeducation has been identified as a key component in the treatment of depression [60], which could address the utility of training cognitive skills as a means to achieve recovery. This psychoeducation component has been found useful by patients in previous studies, such as the study by Lindner et al [61]. It is worth mentioning that 3 of the younger participants considered the VR tasks too infantile or simple to relieve cognitive symptoms of depression, which could be an indication of a generational preference regarding the type of tasks offered through bWell-D. As a result, the inclusion of realistic paraphernalia in the VR environments, as well as the increasing difficulty of the tasks, can potentially address these concerns.

Patients also commented regarding the need of a customizable VR treatment in which they could decide over how, when, and where the treatment was conducted. There was a strong preference for doing the treatment individually at home, because this was considered the most convenient modality for patients. Although considering patients' opinions within any psychiatric or psychological intervention is essential, clinicians should be mindful regarding not losing key components of the intervention when accommodating patients' preferences. By doing so, clinicians might be drifting away from best practice, preventing patients of receiving the best treatment available [62].

There was an overall positive perception toward VR interventions for depression and other mental health conditions, and toward bWell-D itself. Participants indicated that they would use this type of treatment if available, and this acceptance was mainly motivated by the fact that a VR intervention was perceived as a treatment with no adverse long-lasting consequences or side effects. Participants believed that, in the worst-case scenario, the treatment may not improve their cognitive skills but would not worsen them, which was an advantage when compared with other more conventional treatments, such as medication. This relative safety provided by VR treatments can be highly beneficial by end users, given that, besides the economical investment, there are little to no risks associated with this treatment. However, the accessibility concerns manifested by end users should be a consideration for implementation and future directions in the bWell-D development process, given that currently there are no clear plans regarding how this treatment will be made available for clinicians and patients.

This study shares some specific findings with previous literature. In the study by Kramer et al [63], clinicians also indicated a need for more empirical evidence to support the use of VR as an assessment or therapeutic tool, and they also expressed a concern regarding how the use of VR faces challenges regarding its adoption and assimilation. In the study by Thompson et al [64], participants were also worried regarding technological difficulties, mentioning how they might not have access to the necessary equipment to undertake the treatment, and how including a VR intervention in their routine might interfere with patients' schedules. The lack of perceived adverse effects was also highlighted in the study by Nason et al [65], in which patients experienced only minimal motion sickness. As in our own study, Krebs et al [66] found that relatable humanoid avatars are important in virtual environments, given that they promote the suspension of disbelief, which is the key difference between a gamified intervention and a more traditional one. The results of our research join the large body of studies in which VR interventions for mental health issues are perceived positively by end users [67-69]. However, to the best of our knowledge, this is the first study that analyses qualitatively the use of cognitive remediation for cognitive symptoms of depression.

Limitations and Strengths

This research had some limitations. Further insights might have been obtained from participants if they have had hands-on experience with bWell-D, instead of watching prerecorded samples. While it was initially intended that participants would trial bWell-D before completing the qualitative interview, COVID-19 pandemic restrictions prohibited on-site testing during the data collection period, necessitating the change to the virtual format used here. Related to these COVID-19 pandemic restrictions, patient participants were recruited through various web-based sources and self-reported their depression symptoms. Future studies might benefit from in-person assessments in which a health care professional administers the clinical questionnaires. In addition, most of the clinician sample did not have practical experience with cognitive remediation, clinicians with direct experience could have clearer expectations of a VR cognitive remediation treatment and may have therefore provided more extensive feedback. The sample included both people who were still working or in school but had depression-related impairments, as well as people who were off work—these 2 groups might conceivably have different concerns and needs from cognitive remediation. Finally, the clinician sample was formed mostly by psychiatrists working in outpatient settings—a more diverse clinician sample might have provided broader perspectives regarding the use of cognitive remediation and VR for depression. In terms of strengths, this is, to our knowledge, the first study that focused on obtaining end-user feedback regarding a VR intervention for cognitive symptoms of depression with a qualitative approach. We were able to obtain rich and extensive feedback from a varied sample that included patients from a wide range of ages, backgrounds, and genders, which offers an inclusive and comprehensive perspective toward the use of VR and cognitive remediation. Finally, reinterviewing the participants reaffirmed the relevance of the changes made to the program and enhanced the user-centered design, which will continue to be central in the iterative process of bWell-D development until its application in clinical populations.

Conclusions

Virtual interventions for the improvement of cognitive symptoms in depression are generally acceptable and potentially feasible for patients and clinicians. Although VR and its use for the treatment of health-related conditions is relatively new, participants were familiar with it and open to try it, given its perceived safety. They were curious regarding a treatment of this nature and saw potential in its implementation. Participants considered it to be important to have realistic virtual settings, tasks, and cues to enhance the extrapolability of the skills trained in the VR program. The virtual format of this intervention was perceived as an advantage, and participants believed it offered a versatile and fun alternative to conventional depression treatments. Patients' own needs and preferences should be considered when implementing a VR treatment for psychiatric conditions, and all efforts should be made to make it more accessible and convenient for end users.

Abstract

Background: Compared with traditional approaches, gaming strategies are promising interventions for the treatment of attention-deficit/hyperactivity disorder (ADHD). We developed a serious game, The Secret Trail of Moon (TSTM), for ADHD treatment.

Objective: The main objective of this clinical trial was to demonstrate the effectiveness of an add-on, either TSTM or Therapeutic Chess (TC), in previously optimally drug-titrated, clinically stable patients with ADHD.

Methods: This study is a prospective, unicentric, randomized clinical trial in clinically stable patients with ADHD, aged 12 to 22 years. The TSTM (n=35) and TC groups (n=34) performed 12 weekly sessions of their respective treatments. The control group (CG) patients (n=35) were called by phone every week, but they received no cognitive intervention. The primary end point was the change from baseline to end point in the parent “Behavior Rating Inventory of Executive Function-2” (BRIEF-2; patients’ parents) in the per-protocol population (31 serious videogame: 24 TC and 34 CG).

Results: Our study failed to probe clear-cut improvements in the global score of the BRIEF-2. However, the TC group showed improvements in measures of emotional control, emotional regulation, and inattention. The TSTM group showed improvements in measures of emotional regulation, inattention, and school context.

Conclusions: TSTM and TC did not improve executive function symptoms, but they improved ADHD symptomatology related to emotional regulation. Further studies with bigger samples are required to confirm these preliminary findings.

Trial Registration: ClinicalTrials.gov NCT04355065; https://clinicaltrials.gov/ct2/show/NCT04355065

Introduction

Attention-deficit/hyperactivity disorder (ADHD) is the most frequent neurobehavioral disorder, with a worldwide prevalence of 4% to 8% [1,2] and a relative risk of 3:1 against males [3]. ADHD is multicausal; about 70% is due to genetic factors, and the other 30% is due to environmental factors [4]. It is characterized by the presence of 3 core symptoms: inattention, hyperactivity, and impulsivity. These symptoms must be present in 2 or more contexts and interfere with daily functioning [5,6]. Furthermore, patients with ADHD experience a main deficit in prefrontal and anterior areas [7,8], the inferior parietal lobe, supramarginal gyrus, basal ganglia, and premotor area. Deficiencies in both executive functions [9-13] and emotional intelligence [4,14] are critically involved with ADHD.

Reference guides recommend multimodal treatment for ADHD: pharmacological intervention and behavioral therapy—behavioral training (BT) for parents and organizational training for adolescents and adults or a combination [4,15,16]. Unfortunately, multimodal treatment is not always sufficient for the treatment of ADHD symptoms [17,18]. The literature on the efficacy of cognitive behavioral therapy in ADHD is still equivocal, although some trials focused on organizational training in adolescents and adults showed promising results [19-21]. Cognitive behavioral therapy is not recommended in children younger than 10 years. Accordingly, novel strategies are warranted [22-24]. For instance, BTs are the most recommended psychological treatments for ADHD [25]. BTs are aimed at stimulating executive functions, among others [26]. Unfortunately, BTs are financially expensive and may be monotonous for adolescent patients [27]. To address these handicaps, some therapists have begun to use gaming strategies, such as (1) traditional board games like chess [28-30] and Go [31], (2) 2D video games [32-36], and (3) virtual reality serious video games [37-39]. Indeed, in a recent clinical trial including 857 children with ADHD, the patients randomized to Akili Interactive—the first videogame that can be prescribed to patients with ADHD—improved more than those who were randomized to the digital control intervention group [40]. Compared with traditional therapies, gaming strategies have several advantages, such as increased engagement, lower costs [28,41-44], and improved performance [45].

In this context, we developed The Secret Trail of Moon (TSTM), a virtual reality chess-based serious video game aimed at improving attention, impulse control, visuospatial capacity, planning, self-regulation, working memory, reasoning, and cognitive flexibility. TSTM is innovative, motivating, and customizable; it is fun, easy to understand and play, displays enjoyable graphics, and has adequate duration for most participants [39].

This study is aimed at comparing the effectiveness of 2 cognitive gaming strategies in previously optimally drug-titrated, clinically stable patients with ADHD: (1) electronic Therapeutic Chess (TC); and (2) TSTM. Recently, we published the protocol study of our add-on clinical trial [46]. Basically, the TC group received chess lessons and had to solve both traditional chess exercises (related to the video tutorial for each week) and TC exercises. These exercises use the pieces and board but can be done without knowing how to play chess [46]. The control group (CG) received no specific cognitive intervention. We hypothesized that patients randomized to either TSTM or TC, compared to the CG group, would improve in executive functions and ADHD core symptoms.

Methods

Study Design

The study protocol (registered on the ClinicalTrials website: NCT04355065) is published elsewhere [46], but it is basically a prospective, unicentric, randomized, non-equality trial in 105 patients with ADHD. All participants were clinically stable before baseline. Subjects were randomized into 3 groups: TC group (electronic cognitive training with TC), TSTM group (cognitive training using TSTM), and CG (patients were called by phone every week, but they received no cognitive intervention). The allocation ratio was equal in all 3 groups (n=35 per branch).

Ethics Approval

The study was approved by the Ethics Committee of the Puerta de Hierro University Hospital in Majadahonda on December 2, 2019 (PI 187/19).

Study Population

The clinical trial included children, adolescents, and young adults between the ages of 12 and 22 years (mean age 14.38, SD 2.26 years). The minimum participation age was 12 because virtual reality is discouraged for children younger than 12 years. The maximum age was 22 because brain maturation continues until that age, approximately [47,48]. Furthermore, adolescent patients admitted in Child and Adolescent Psychiatry units are progressively referred to be followed up in Adult Psychiatry services, which means that patients up to the age of 20 (and occasionally 22) years are already followed up in Child and Adolescent Psychiatry units [46]. Inclusion criteria were as follows: adolescents or young adults between the ages of 12 and 22 years with a diagnosis of ADHD and clinically stable on any medication related to ADHD, meaning that participants had a consistent drug prescription and were not allowed to change it during their participation; however, during the trial, 5 participants changed their medication, another 5 participants increased their medication dosages, another 5 participants decreased their medication dosages, and medication was removed for another participant. Exclusion criteria were the following: comorbidities with autism or intellectual disability, epilepsy, or another severe clinical condition; plans to begin another clinical treatment or moving out during the following 3 months; and risk of suicide [46]. A total of 105 patients (35 per group) were recruited for the clinical trial, of which 47 (45.2%) had an inattentive ADHD subtype and 57 (54.8%) had a mixed ADHD subtype.

The participants were recruited between December 18, 2019, and November 16, 2020. The last evaluation was performed on February 6, 2021.

Randomization and Masking

To warrant clinical trial randomization, AR generated a sequence of random numbers through Epidat 4.2 software (Dirección Xeral de Saúde Pública, Xunta de Galicia). The 105 patients were randomly assigned to the 3 groups by HBF following the randomized sequence. Each randomization number was introduced inside a closed, opaque envelope. When a patient came to the hospital to participate in the trial, the inclusion and exclusion criteria were applied to them (one participant was excluded then); the patients and their parents received and signed informed consents, and after the first assessment (D0), each participant received and opened the envelope corresponding to their inclusion number, and the group assigned to that number.

Study Interventions

Visits

The number of visits depended on the group. The TSTM group made 15 in-person visits over 3 months: pre-inclusion visit, inclusion visit (D0), 12 cognitive treatment visits (1 per week) with TSTM, and one final visit (D90).

The TC and CG groups made 3 in-person visits over 3 months: pre-inclusion visit, inclusion visit (D0), and postassessment visit (D90). A total of 12 remote (web- or phone-based) visits were also made during the 3 months.

Interventions

A more detailed description of the intervention groups can be found elsewhere [46]. Basically, the interventions were different for each group, as follows:

- Cognitive intervention with TSTM (TSTM group): TSTM was constructed for 5 different cognitive training mechanisms: smasher, enigma, teka-teki, kuburi, and chess. Each session was divided into 3 blocks (2 blocks for training into 2 different game mechanics and a chess training block). Sessions were personalized in the sense that difficulty levels were adjusted, taking into account individual performance.
- Cognitive intervention with TC (TC group): in the initial visit, each patient received a flash drive containing the 12 training sessions in TC. Every session was divided into 3 parts: video tutorials, traditional chess exercises, and TC exercises.
- Control group intervention (CG group): each patient received 12 phone communications (1 per week). In these communications, they were asked about medication usage, mood, and school performance, among other issues.

Study Outcomes

Primary Outcome

The primary end point was the change from baseline to the end of treatment in the "Behavior Rating Inventory of Executive Function-2" (BRIEF-2) questionnaire filled out by the patients' parents [49,50]. This scale consists of 63 items and 4 main indicators: emotional regulation, cognitive regulation, behavioral regulation, and executive function global index. The design of TSTM is based on cognitive training and task and aimed at improving executive functions [39]. Additionally, TC has shown a certain effect on executive functions [28].

Secondary and Safety Outcomes

Secondary measures were the ATENTO questionnaire [51], with versions for patients and for parents; the emotional intelligence inventory by the BarOn model of Emotional Quotient Inventory (BarOn EQ-i: Youth Version), with a version for younger people [52]; the ADHD rating scale V (ADHD-V); the quantitative scale by Swanson, Nolan, and Pelham (SNAP-IV) [53]; the Conners' Parent Rating Scale (CPRS-HI) [54]; and the Conners' Continuous Performance Test 3 (CPT-3) for computers [55]. In addition, the TSTM group filled out the Udvalg für Kliniske Undersolgester (UKU) questionnaire [56,57].

Statistics

Sample-Size Calculation

Sample sizes were calculated for 80% of statistical power, assuming 2-tailed Student *t* tests for comparison between groups, with a 1:1:1 proportion, assuming a 20% loss. In each group, 35 patients were included (a total of 105 patients).

Analyses

Analyses were performed for two types of populations: analyses for treatment intention (ATI) and analysis per protocol (PP). In ATI, data were analyzed according to the assigned treatment for each patient. In PP, data were analyzed according to the treatment that each patient completed.

A descriptive analysis was performed for qualitative variables using absolute and relative frequencies. For quantitative variables, the median and the quartiles 1 and 3 were used as descriptive statistics.

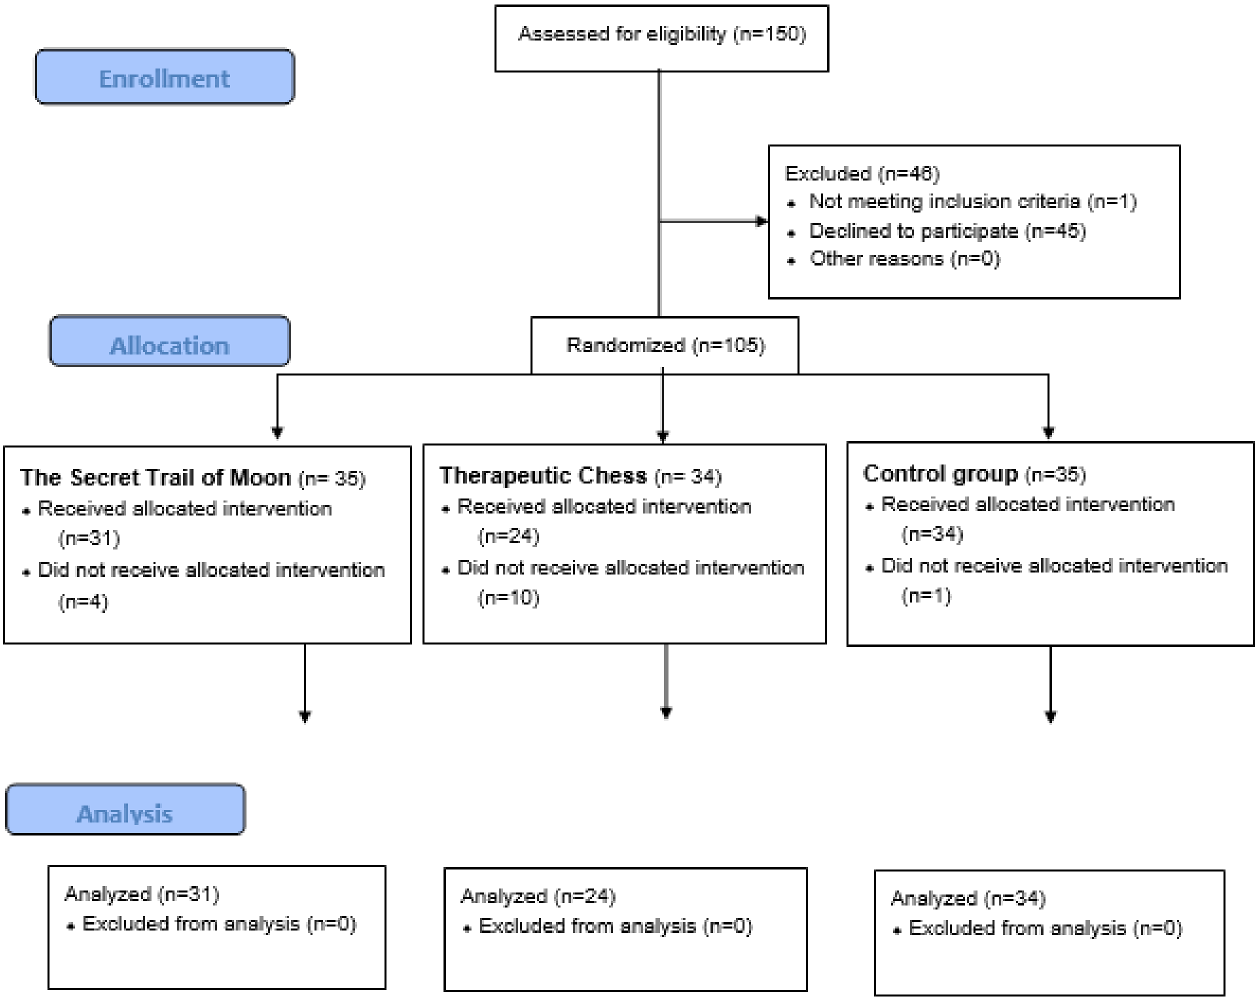
To compare the groups TSTM versus CG and TC versus CG, 2 series of analyses were performed in parallel. To compare the basal and final differences, the Kruskal-Wallis test was performed, as the normality assumption for ANOVAs and *t* tests was generally violated. The signification level was fixed at P=.10 mainly due to the pandemic situation and the early stage of this trial [58]. Subsequently, for those variables reaching statistical significance in Kruskal-Wallis tests, pairwise Mann-Whitney tests were performed to compare pairs of experimental groups. The effect sizes were estimated through ε^2 for Kruskal-Wallis tests and η^2 for Mann-Whitney tests [59]. The statistical package SPSS 26 (IBM Corp) was used to perform the tests. Ultimately, the study was powered to detect an effect of Cohen $d \geq 0.52$ in two-way comparisons.

Results

Patient Inclusion and Randomization

A total of 105 patients agreed to participate in the trial and signed a reported consent form. Ultimately, 1 patient was excluded for having a previously unreported history of epilepsy. The other 104 patients were randomized to one of 3 groups: TSTM (n=35), TC (n=34), and CG (n=35). Figure 1 shows a flow diagram describing in detail the number of participants in each trial stage.

Figure 1. CONSORT Flow Diagram for the number of participants in each stage of the trial.



Baseline Characteristics

In the PP population at D90, participants were male in 71.9% (64/89) of the cases (TSTM group: 27/31, 87.1%; TC group: 19/24, 79.2%; and CG: 18/34, 53.1%). The mean ages for the groups were 14.7 (SD 2.4) for TSTM, 13.8 (SD 1.9) for TC, and 14.8 (SD 2.4) for CG. Table 1 and Table 2 show all the sociodemographic and baseline variables.

[a]TSTM: The Secret Trail of Moon.
[b]TC: Therapeutic Chess.
[c]CG: control group.
[d]N/A: not applicable.
[e]ADHD: attention-deficit/hyperactivity disorder.

The BRIEF-2 questionnaire shows that the TSTM group performed better than the TC and CG groups in "working memory," "planification and organization," and "cognitive regulation" scales, the groups being approximately equal in the rest of the BRIEF-2 scales (Tables S1 and S2 in Multimedia Appendix 1 present descriptive baseline characteristics).

For both primary and secondary outcomes, we calculated individual pre-post differences and used these differences as the dependent variables in our tests.

Primary Outcomes

The goal of this study was ultimately to compare the changes between D0 and D90 in every group as well as the differences among groups. The main measurement for testing the differences were the BRIEF-2 scores, according to the indications already presented elsewhere [46]. The groups were compared through Kruskal-Wallis tests.

ATI showed improvements for the TC group compared to the CG group in "emotional control" and "emotional regulation" ($P<.10$) scores. PP also showed a significant difference in "emotional control" between the TC and CG groups ($P<.10$). None of the rest of the comparisons reached a statistical significance. All tests and significance levels are shown in Tables 3 and Table 4.

[a]TSTM: The Secret Trail of Moon.
[b]TC: Therapeutic Chess.
[c]CG: control group.
[d]Not applicable.
[e]EQ-i:YV Emotional Quotient Inventory: Youth Version.
[f]CPT-3: Continuous Performance Test 3.

According to the protocol study of our add-on clinical trial [46], scores on ADHD-5, CPRS, SNAP-IV, ATENTO, BarOn EQ-i:YV, and CPT-3 tests are considered secondary end point analyses. The groups were compared by means of Kruskal-Wallis tests and, subsequently, Mann-Whitney tests. Neither SNAP-IV nor CPRS-HI scores showed significant differences between CG and any of the other groups. ATENTO (parents' reports) showed no significant differences between the CG and the other groups.

ATENTO (self-report) scores showed a significant difference between the TSTM and CG groups in "school context" (P<.10). Additionally, the TC group showed a statistically significant difference with the CG in "time orientation" measures. None of the other comparisons reached statistical significance.

BarOn EQ-i:YV scores showed statistically significant differences between the TSTM and CG groups in "positive impression" on the interpersonal scales (P<.10). None of the remaining comparisons reached statistical significance.

CPT-3 scores showed differential improvements in "block change" and "inter stimulus change" in the TSTM group compared with the control group and differences in improvements in "block change" between the TC and control groups (P<.10). None of the other comparisons reached statistical significance.

Discussion

Principal Findings

This prospective, unicentric, randomized study in clinically drug-stable children with ADHD did not confirm our hypothesis that using an augmentation strategy (either TSTM or TC) may improve executive functions as measured by the BRIEF-2 total scores. An exception was the improvement in emotional control and regulation as measured by the BRIEF-2 in the TC group. Furthermore, significant pre-post symptom reductions were found for several scales measuring secondary end points, and they differ depending on the type of intervention (as explained in the following sections).

TSTM

We found no improvements in executive functioning after using TSTM. This finding is consistent with literature using other serious video games such as ACTIVATE [60] or Plan-It Commander [61]. However, this last video game demonstrated improvements in working memory and planification skills, which have not been observed in our study. In addition, a recent review found that some video games may be beneficial for executive function training in patients with ADHD [62].

However, we found that the TSTM group showed better posttreatment scores in core ADHD symptoms, in particular inattentive symptoms, compared to the CG, mainly in self-reported tests. Moreover, parents reported improvements in social and school skills, consistent with results coming from studies using other serious video games like Plan-It Commander [61] and ThinkRx [63].

But the most relevant finding is that the TSTM group, compared to the CG, showed some improvement in some emotional domains. Both self-reports and parent reports provided better scores on scales related to emotional intelligence, emotional regulation, and performance in school context compared to the CG, which is in keeping with some other literature [64-67]. Better than a purely cognitive tool, the TSTM video game may serve as a way to train and improve self-regulation and social skills through facing challenging problems and competitions with a social component.

TC

As was the case with TSTM, we did not find any improvement in the TC group when compared with the CG, with the remarkable exception of emotional control and regulation. This negative finding is in contradiction with several studies reporting improvements in executive functioning using a therapy based on board games (eg, chess and Go) [31]. Demily et al [68] reported that patients with schizophrenia who played chess for just 10 sessions improved executive functioning (z=–3.41). Finally, a recent systematic review and meta-analysis suggested that some of these board games may improve self-efficacy, attitudes, social functioning, and executive functions [69]. Our negative findings might be explained either by differences in the studied populations (the studies were devoted to patients with diagnoses apart from ADHD) or that TC was implemented electronically.

However, core ADHD symptoms benefited from TC. In particular, inattentive symptoms improved most in the TC group when compared with the CG. This result is consistent with that obtained in a pilot study using chess in children with ADHD [28]. Furthermore, as was the case with TSTM, the greatest improvements obtained by TC training were in the emotional and interpersonal spheres. Significantly better improvements were shown in emotional intelligence, emotional regulation and control, as well as interpersonal scales, as measured by the BRIEF-2 and BarOn EQ-i:YV scores. Our findings are in keeping with previous studies reporting that chess training has shown good results in emotional intelligence development [30,70].

Strengths and Limitations

The main strength of this study is the use of 2 gaming strategies for treating ADHD, following an add-on strategy with clinically stable patients; one of them was disruptive—the use of a serious video game (TSTM)—and the other (TC) was more traditional, thus allowing for testing the effectiveness of each tool in executive functions and ADHD core symptoms. In contrast, the main limitation was the irruption of the COVID-19 pandemic, which impacted the clinical trial, as some patients randomized to the TSTM group had more difficulty completing the cognitive training sessions. Another limitation was the use of just one TSTM session per week in the TSTM group, which may have limited the effectiveness of this cognitive training. Accordingly, we plan to include a 2-3 session-per-week strategy in the next clinical trial using TSTM, scheduled to begin in April 2023. Furthermore, the evaluation was not blind and was based on clinical judgment and either self-report or parental reports. However, previous work states that teachers, rather than parents, tend to be the most reliable external observers of ADHD symptoms in children [71]. Furthermore, we used the CPT-3 to have an objective measure of our results. Another limitation was the difference between the ATI and the PP populations. Samples sizes for the groups were not very different, but a potential survival bias may have conditioned our results. It is possible that adherence to treatment was conditioned by the differential attractiveness of the video game and TC, that is, children who like video games or chess were more likely to complete the trial, and that could bias the results for the PP population. Indeed, in the PP analyses, fewer patients finished the TC intervention in the TC group. It is possible that only those patients with ADHD who were motivated or who liked chess finished the treatment, thus biasing our results in the TC arm. Another difference is the alternate location of the TSTM treatment, administered in our hospital, compared to the TC treatment, self-administered at the patients' homes. Moreover, a possible limitation is the use of drug-stable samples; perhaps the effects of playing serious video games or TC may be more prominent in patients without a stable pharmacological treatment. Furthermore, to have clinical samples as representative and general as possible, we recruited participants in a wide age range, but our samples were not large enough to allow for analyses across developmental stages; future research should study in depth the differential effects across ages. Finally, the lack of a long-term follow-up approach kept us from studying the maintenance of any beneficial effect over time.

Conclusions

Neither TSTM nor TC produced a significant improvement in the executive functioning of patients with ADHD who were clinically stable on ADHD drugs. However, both TSTM and TC produced a significant improvement in some ADHD symptoms, particularly in emotional regulation areas. Further studies are warranted to extend these preliminary but motivating findings.

Acknowledgments

We thankfully acknowledge Lorraine Maw, MA, for her support in proofreading the manuscript.

This research was partially funded by the Spanish National Project (grant RTI2018-101857-B-I00), an iPFIS (Contratos Predoctorales de Formación e Investigación en Salud) research contract (Instituto de Salud Carlos III IFI16/00039), a grant from the Fundación para la Innovación y la Prospectiva en Salud en España, and an intensification of research activity for health professionals grant (2019) from the Puerta de Hierro Health Research Institute-Segovia de Arana.

Authors' Contributions

MRY and MMM conceptualized the study and were in charge of the software, investigation, data curation, writing the original draft, and funding acquisition. MMM also reviewed and edited the manuscript. CGT contributed to the conceptualization and the software.

FSS provided resources. AR conducted the methodology, formal analysis, and data curation. MBF contributed to the formal analysis as well as writing, reviewing, and editing the manuscript. HBF conceptualized the study; provided resources; contributed to the writing, reviewing, and editing the manuscript; supervised the study; and was also in charge of funding acquisition.

Conflicts of Interest

In the last 24 months, HBF has received lecture fees from Shire. He is the principal investigator (PI) of an iPFIS (Contratos Predoctorales de Formación e Investigación en Salud) research contract (Instituto de Salud Carlos III; IFI16/00039) and the co-PI of a MINECO research grant (RTI2018-101857-B-I00); he is the recipient of (1) a grant from the Fundación para la Innovación y la Prospectiva en Salud en España and (2) an intensification grant from Puerta de Hierro Health Research Institute-Segovia de Arana; involved in 2 clinical trials (Mensia Koala, NEWROFEED Study; ESKETSUI2002); and the cofounder and CEO of Haglaia Solutions. He is also an employee and member of the advisory board of Ita Salud Mental (Korian). MMM is the recipient of a grant from the Centro para el Desarrollo Tecnológico y la Innovación, funded by the European Fund for Regional Development (IDI-20180701; file 00107278). The remaining authors do not have any conflicts of interest.

Editorial notice: This randomized study was only retrospectively registered, as the authors thought it to be registered, but after starting the trial realized that it had not been registered. The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials because the risk of bias appears low and the study was considered formative, guiding the development of the application. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: Currently, many central auditory processing disorder screening tests are available for children, and serious games (SGs) are frequently used as a tool for the diagnosis of different neural deficits and disorders in health care. However, it has not been possible to find a proposal that unifies both ideas. In addition, the validation and improvement of SGs, in general, does not take into account the player-game interaction, thus omitting valuable information about the playability and usability of the game.

Objective: This study presented Amalia's Planet, a game conceived for use in school environments, which allows a first assessment of a child through their performance of the proposed tasks related to different aspects of auditory performance. In addition, the game defines a series of events in relation to the execution of the tasks, which were evaluated for the subsequent optimization of its performance and the improvement of its usability.

Methods: Using screening tools based on the use of SG technologies, a total of 87 school-age children were evaluated to test the various hypotheses proposed in this study. By grouping users according to whether they had personal history of hearing pathologies, the discriminant power, playability, and usability of the final solution were examined using traditional statistical techniques and process mining (PM) algorithms.

Results: With a confidence level of 80% for test 2 (P=.19), there was no statistical evidence to reject the null hypothesis that a player's performance is affected by whether the player had a previous auditory pathology. Furthermore, the tool allowed the screening of 2 players initially categorized as *healthy* because of their low level of performance in the tests and the similarity of their behavior with that of the group of children with a previous pathology. With regard to the validation of the proposed solution, the use of PM techniques made it possible to detect the existence of events that lasted too long, which can lead to player frustration, and to discover small structural flaws in the game.

Conclusions: SGs seem to be an appropriate tool for the screening of children at risk of central auditory processing disorder. Moreover, the set of PM techniques provides a reliable source of information regarding the playability and usability of the solution to the development team, allowing its continuous optimization.

Introduction

Goal of This Study

Owing to their high degree of neuroplasticity, children and young people can be highly influenced by the stimuli they receive from the environment around them. Given the nature of central auditory processing disorder (CAPD), it is believed that the inclusion of auditory stimulation may lead to functional changes in the individual's central auditory nervous system [1]. More specifically, "children come to experience greater and more complex demands on central auditory processing as they face more academically, intellectually and linguistically demanding challenges" [2].

Before the therapeutic treatment of CAPD, it is necessary to carry out a diagnostic or screening process so that the presence of the pathology can be detected, thus facilitating a prognosis and the suppression or reduction of the limitations that it may cause in the patient. Among the diagnostic and rehabilitation tools for different pathologies are the well-known serious games (SGs). According to Piaget [3], "games form a part of the child's intelligence, because they represent the functional or reproductive assimilation of the reality." However, despite the existence of numerous screening tests for CAPD [4] and the more than palpable efficacy of SGs in multiple settings [5], it has not been possible to find a project in which these 2 techniques are unified to support the screening of individuals who may have the disorder in question.

In the field of SGs, there is a wide variety of methodologies that guide the development and validation of such tools according to their purpose [6-8]. Despite this, most game evaluation and optimization processes focus on game performance, omitting a complete analysis of the player-game interaction, which includes other relevant aspects such as playability, usability, and game understanding. At this point, it is important to highlight the fact that the term *usability* refers to "the extent to which a system (product or service) can be used to achieve the goals with effectiveness, efficiency, and satisfaction in a specified use context" [9].

Process mining (PM) techniques can be used to deepen our knowledge about this player-game interaction. PM allows for the discovery of patterns and tendencies, even without previous models, enabling and improving the comprehension of real processes by recording events. "Process Mining aims to discover, monitor, and improve real processes by extracting knowledge from event logs readily available in today's information systems" [10].

In view of this, the main objective of this research was to develop and validate a screening tool for CAPD based on the SGs technology, supporting the diagnosis of the disorder in school-age children. Amalia's Planet was conceived as a game for use in school environments, which allows a first assessment of a child through their achievement of the different proposed tasks related to auditory discrimination, lateralization and localization of sounds, and different aspects of auditory performance. In addition, the game defines a series of events in relation to the execution of the tasks, which were evaluated using PM techniques for the subsequent optimization of its performance and improvement of its usability [11].

It is important to note that throughout this paper, SG is defined according to the study by Tarja et al [12], which stated that an SG is "any game whose main purpose goes beyond the mere entertainment."

Background

The American Speech-Language-Hearing Association uses the term CAPD to refer to deficits in the neural processing of auditory information in the central auditory nervous system not due to higher-order language or cognition, as demonstrated by poor performance in one or more of the skills used to preserve, refine, analyze, modify, organize, and interpret information from the auditory periphery [13].

As indicated in the technical reports published by the Working Group on Auditory Processing Disorders, the process of training the abilities affected by CAPD should be implemented as early as possible, taking advantage of the plasticity and cortical reorganization characteristics of the human brain [13,14]. This principle of action could have a much more positive impact on children because the maturation of the cerebral cortex and creation of neural interconnections occur during childhood. Therefore, from the perspective of the consequent therapeutic process, diagnostic testing or screening for CAPD in school-age children is highly desirable. Undiagnosed children often present with learning disabilities, occasionally mistaken for other pathologies simply because auditory processing problems were not considered.

Currently, there are different tools that allow the observation and subsequent screening and diagnosis of CAPD in individuals. Focusing on children, the Hearing in Noise Test for Children [15] lists a total of 130 sentences to determine the quality of information received by an individual in a noise context. Similarly, the Pediatric Speech Intelligibility test proposes a context of overlapping sounds, with relevant and distracting information being uttered in the same or opposite ears [16,17]. The Test Everyday Attention for Children [18] focuses on the assessment of different aspects of an individual that determine their attention levels [19]. Despite their proven efficacy, all these tests tend to be time-consuming and depend on a high degree of specialization on the part of professionals, which restricts their accessibility for the general child population.

Through the use of SGs, a greater number of children can simultaneously take different screening tests, requiring only the company of their relatives or educators and being able to carry out the activity in a familiar environment. Added to these facilities is the fact that because evaluation is performed using a game, the child is stimulated during the process. Finally, another notable advantage of the use of these technologies is that they allow for their evaluation and consequent evolution, making it possible to add different criteria or informative factors in the future as well as to optimize the existing ones. Despite these advantages and the existence of some games focused on the therapeutic process of CAPD, it has not been possible to find a game with these characteristics for the screening of children with CAPD [20-23].

The self-evaluation feature and potential evolution of the games are made possible by the validation process carried out after the use of the games by the end users. During this process, the characteristics of the tool, such as its playability, usability, and discriminating power, must be evaluated. Owing to the lack of publications related to the generation of CAPD-screening SGs for children, different methodologies proposed for the development and validation of this type of technology in the health field have been reviewed. However, most of them base the validation of the tool on performance indicators without assessing aspects of the individual or the tool that may alter the value of these parameters. In the first place, Verschueren et al [24] generated a framework for the conception of SGs for health. This framework was created to ensure that the final product is relevant, theoretically driven, and evidence based through 5 stages. More centered on auditory impairments, Cano et al [25] carried out an exhaustive study of different methodologies for the conception of SGs. According to the authors, all methodologies lacked a register of the player's learning in a quantitative manner. After learning about the successes and failures of these methodologies, they created the *metodología para la concepción de juegos serios para niños con discapacidad auditiva* (MECONESIS) methodology. MECONESIS is a methodology consisting of 4 stages, namely analysis, preproduction, production, postproduction, and is based on 6 models, namely the analysis, user, pedagogical objective, task, scenario, and validation models.

Among the methodologies that take into account the player-game interaction, the one proposed by Serrano et al [26] in 2014 stands out. The authors proposed a "framework to improve evaluation in educational games." On the basis of learning analytics and game analytics techniques, the authors suggest a Learning Analytic Model and Learning Analytic System, in which the authors point to some events carried out by players on a graphical interface, the evolution of game stages, and even some logic events. Despite all these sources of information, no tool or model capable of analyzing the collected information was provided.

PM, as a set of techniques designed to extract information from existing data in activity log files, draws on the so-called *event logs* or *game events* from different systems, allows them to be cleaned, establishes contextual relationships, and presents them graphically to facilitate decision-making [27]. This tool provides great advantages to those who use it, among which 3 are worth highlighting in this study [9,28]:

1. PM is based on real events; therefore, the information collected and analyzed is a reflection of reality. It is obvious that, in general, when extracting information for reaching a series of conclusions, the aim is to gather information that is as representative of reality as possible. However, traditional statistical techniques, for example, try to extract such information from a sample of a specific population (sampling techniques). That is, a sampling behavior is generalized to the entire population. In addition, statistics have techniques for the elimination of so-called missing values and outliers so that their presence does not affect the final conclusions that can be reached. For its part, PM works with all the information collected in the *event logs*, thanks to its high degree of automation. Thus, behaviors are neither generalized nor modified. Atypical behaviors are taken into account and compared with standard or normal behaviors.
2. It includes a set of defined algorithms, which allow complex events to be analyzed and conclusions to be drawn to improve the system. That is, PM provides the capability to analyze and optimize the system. Every system, tool, and environment in its first phase of development and throughout its use must be evaluated and updated for its correct functioning. The aim is not only to optimize the system in terms of performance but also to adapt the system to the end user so that it provides the desired usability.
3. It presents the analyzed information in a visual manner, making it easily understandable by any user, to facilitate the decision-making process.

All these advantages make PM the ideal tool for the future optimization and improvement of the SG proposed in this study.

Methods

Overview

Amalia's Planet was conceived as an SG for use in the school environment, which allows a first detection of children at risk of CAPD through their completion of the different tasks proposed. Therefore, through the game and the proposed activities, schools will be able to perform screening in cases in which there is no suspicion of CAPD or in which such suspicion is not entirely clear. In addition, the game defines a series of events in relation to the execution of the tasks, which were evaluated using PM techniques for the subsequent optimization of its performance and improvement of its usability.

From the aforementioned statement, 2 conclusions regarding the approach to the solution are evident. First, a multidisciplinary team must be assembled to cover the wide variety of fields of expertise required for the correct deployment of the solution. In this regard, the team was composed of 3 engineers; 1 PM expert; 1 occupational therapist; 2 audiologists; and 1 ear, nose, and throat specialist. Second, the development of the solution must be approached from 2 points of view: in terms of the health field, there is a need to develop a screening tool with discriminant power for children at risk of CAPD and, in terms of new technologies and data analysis, there is a need to develop of a game that provides relevant information related to different aspects of playability and usability to allow for its evaluation and subsequent optimization.

Nonetheless, although the existence of the aforementioned 2 approaches (health and technological or analytical) is clear, it should not be forgotten that the proposed solution is one and has to cover all the requirements that have been imposed in each of the 2 approaches. This is why, later in this paper, both approaches are mentioned simultaneously.

Ethics Approval

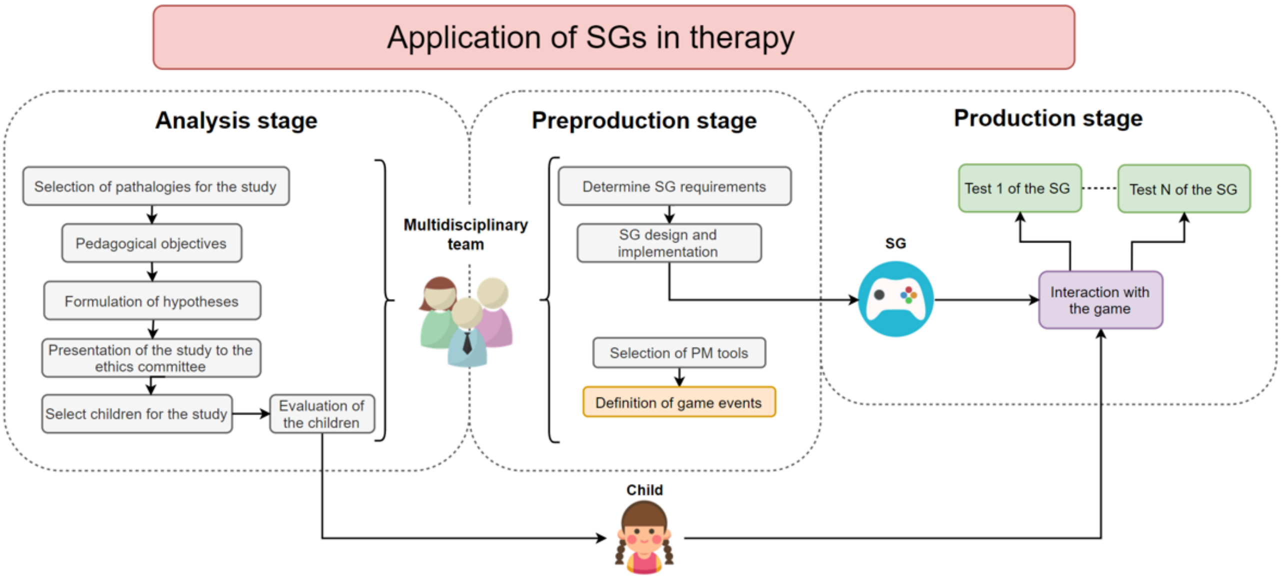
This study was approved by the Ethics Committee of the Rey Juan Carlos University (reference 1203201805218). The trial was conducted in accordance with the Declaration of Helsinki, as amended in October 2013 by the 64th World Medical Association General Assembly [29].

Amalia's Planet for Screening Children at Risk of CAPD

As there is no unified screening method for CAPD, current standard screening methods for CAPD include observing the listening process, recording the patient's behavior, and performing a series of tests that examine the patient's auditory function performance [30]. In general, individuals with CAPD have difficulty discriminating sounds, impaired ability to determine the stimulated ear and location of the sound source, and problems processing nonverbal acoustic signals and recognizing the order or pattern of presentation of certain stimuli [31]. These and other conditions experienced by affected individuals should serve as indicators for the tool so that it can detect the presence of the pathology.

In addition, the proposed solution is oriented toward its use among school-age children. As children are the end users for whom the solution is developed, it should take into account not only the characteristics of the disorder to be studied but also the characteristics of the age range of the users. In other words, the game should present an attractive and a motivating environment for children, making them increase their commitment when interacting with the tool. Figure 1 presents an outline of the process of developing the game as a screening tool.

Figure 1. Phase 1: deployment of a screening tool for school-aged children from a health care perspective. PM: process mining; SG: serious game.

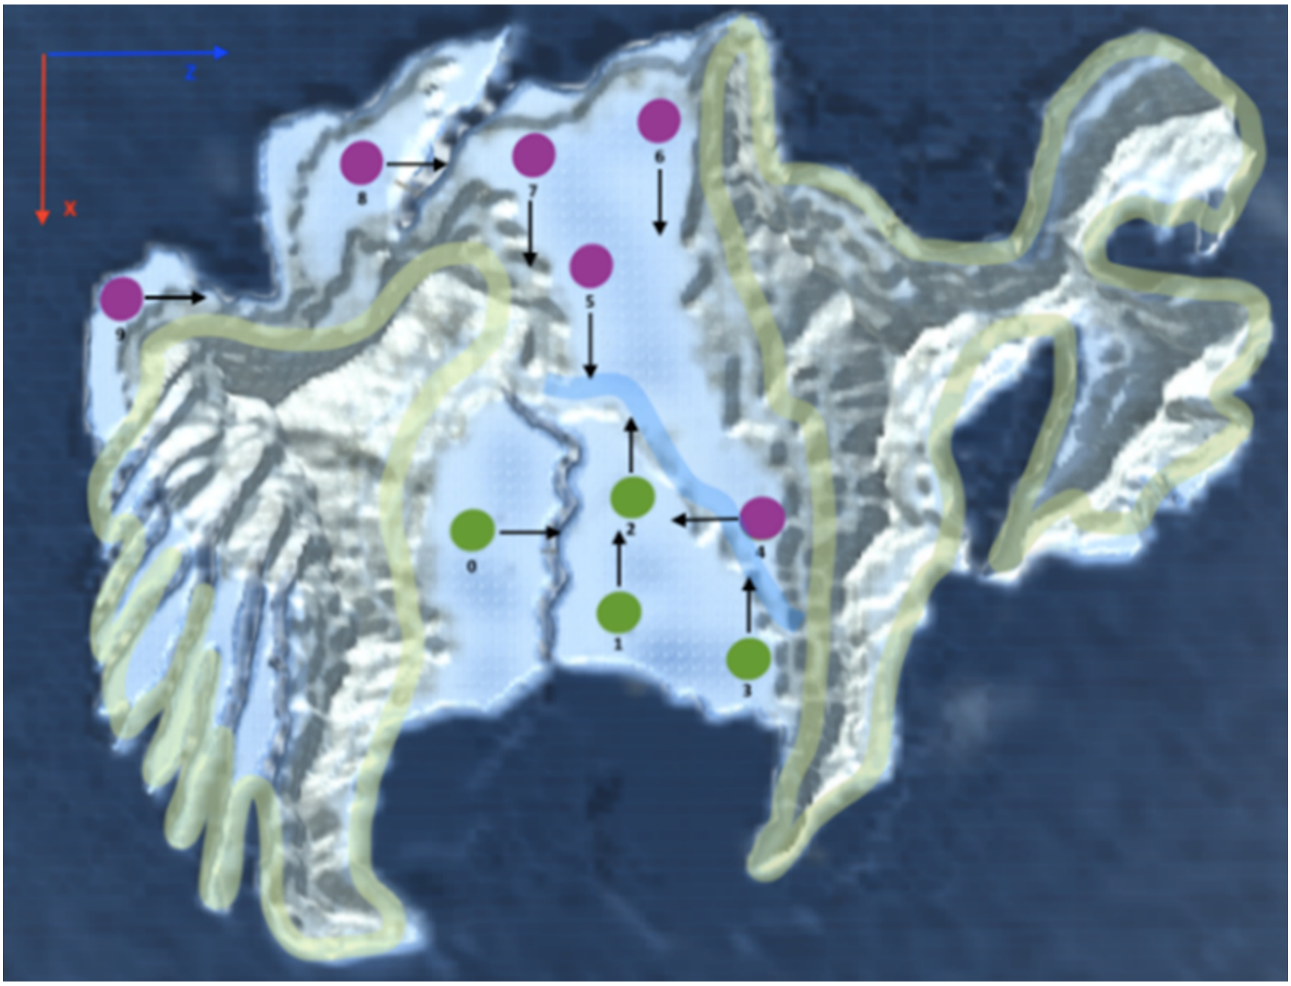


Amalia's Planet is set, as the name suggests, on a planet consisting of multiple modules ("habitats" or "islands") of different types. Each "habitat" is home to a different type of animal and incorporates multiple mini-games, all created with a simple cartoon design, making them easily accessible to primary-school children. The animals chosen are those that normally form herds or flocks, and they emit different sounds that are collectively handled as "noise." This makes it possible to establish noisy backgrounds that produce sound and visual distractions for the child and thus forces them to train listening skills where they have difficulties.

Located in Antarctica, the habitat presented in this paper focuses on the assessment of certain skills affected by various CAPD-related pathologies. More specifically, the skills assessed in the first module are auditory discrimination, sound localization, auditory memory, and auditory separation in noise. For this, the habitat has a series of mini-games, which sequentially assess the mentioned skills. Each of these mini-games provides a series of stimuli and rewards throughout the game so that the player's motivation is maintained.

As the first mini-game in the Antarctic habitat, the child has to find a stray baby penguin of a herd in a wide area guided only by the sound generated by the animal (auditory localization). The original positions assigned to both the penguin and player are randomly chosen by the game each time the game starts (Figure 2). As a measure of the individual's performance in this test, the time taken to find the little penguin is collected. Once the child finds the little penguin, this achievement is celebrated by the herd through an applause given to the player.

Figure 2. Semirandom distribution of start points and locations of the group of penguins. The yellow lines mark the unreachable areas. The blue line is a slope in the terrain. The green and violet dots are the possible positions of the player and the flock.



Once the player passes the first test, the second mini-game starts automatically (Figure 3). This is an auditory memory game. Playing with the head penguin, the child must be able to memorize the sequences of sounds produced by the penguin. Each of the sequences emitted by the head penguin can comprise a series of sounds that the player would have to remember: clapping the wings, twinkling an eye, rattling the beak, and stomping a foot. For the player to become familiar with the aforementioned sounds, the penguin first exposes them together with an animated movement (visual aid). Once the child is deemed to have the necessary information to play the game independently, the penguin hides within its huddle (disappearance of the visual aid) and proceeds to emit sequences of sounds in a given order. The player must remember both the sounds heard and the order in which they were produced to reproduce them once the penguin finishes emitting the sounds.

With regard to the length of the sequences, they become more complex as the child passes the tests. The number of sounds to be distinguished and the length of the sequence emitted by the animal gradually increase in 3 different levels of difficulty, each of which consists of 3 sublevels (Figure 4). In addition, each sublevel provides the individual with 3 opportunities to pass, and if all 3 opportunities are exhausted without success, the sublevel and its corresponding level shall be considered as not passed. If the player manages to pass any of the levels, applause starts to ring out, and the penguin congratulates the player so that they feel motivated and satisfied with the task performed. If the player does not manage to complete any of the tasks correctly, the penguin encourages them to continue playing (thereby trying to avoid frustration and abandonment) and repeats the sequence of sounds that the child has to recreate.

In addition, the game allows the configuration of this auditory memory test for the evaluation of auditory discrimination skills and sound separation in noise. If desired, the penguin colony hiding the main penguin will emit noise to distract the player, demanding higher auditory abilities. This background sound is adjustable for each player and can vary between 0 dB and 30 dB.

Figure 3. Sequence exposure in the second mini-game.

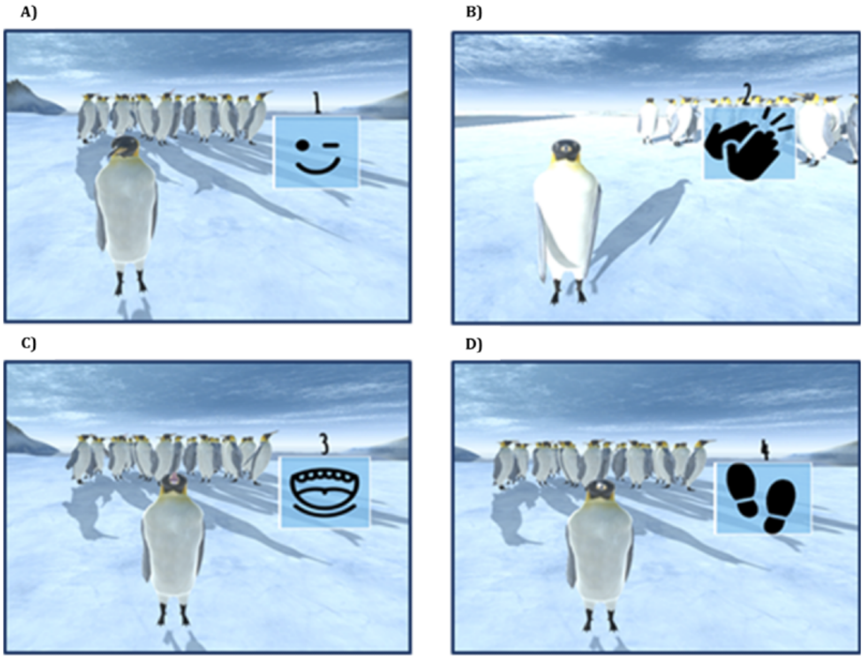


Figure 4. Structure of levels and sublevels to pass in the second mini-game.

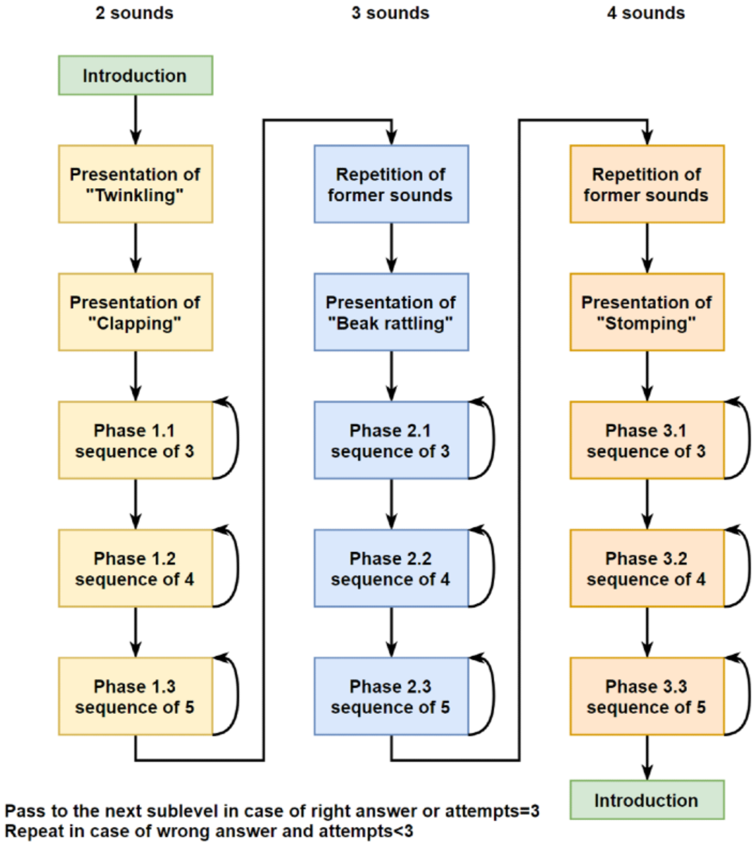


Amalia's Planet as Its Self-evaluator

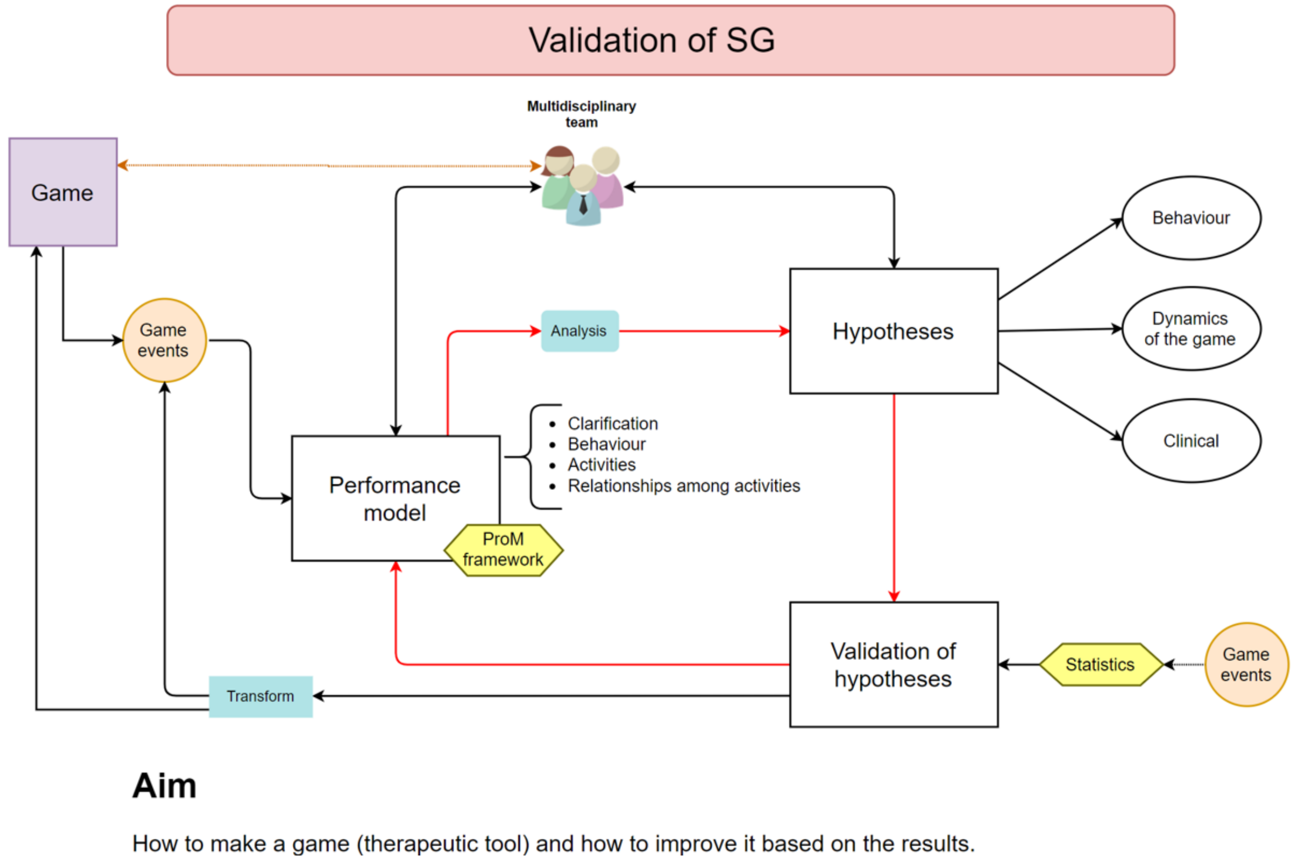
The postproduction stage "corresponds to the evaluation of the serious game, where an evaluation model is proposed, taking into account 2 roles of evaluators, the end user and the expert" [25]. It is at this stage that the previously mentioned PM techniques were introduced as a novel tool for the validation of the proposed solution. However, as reflected in Figure 1, it was at the preproduction stage that the *event logs* that would be analyzed later have to be determined.

Because information was collected in the system logs, it allowed the definition of events by the team, which provided flexibility when addressing problems. Looking at the structure of the game (Figure 4) and with the idea of knowing the behavior of the players throughout the game, the team defined the events according to the result that the player had obtained in each sublevel. At this point, 3 possible outcomes were defined:

1. Passing the sublevel: the player reproduces all the sounds of the sequence in the correct order.
2. Omitting the sublevel: the player does not reproduce all the sounds in the sequence. This result was considered a failure.
3. Failing the sublevel: the player either does not reproduce all the sounds of the sequence correctly or does not reproduce the sounds in the correct order.

Thus, the traces of the event logs consisted of events that report the path followed by each player throughout their progress in the game. This definition of events allowed us to know the basic behaviors of the players, such as the number of attempts a player needed to pass a level and the nature of the level (omission or failure). In addition, it allowed us to recognize patterns of interest that could occur, such as more frequent cycles, traces, or paths among players that are not easily perceived using conventional statistical tools. Figure 5 schematically shows the tool validation process proposed by the development team.

Figure 5. Phase 2: Proposed Amalia's Planet validation process. SG: serious game.



The information provided by PM about the system's functioning, performance, and use as a tool for achieving specific objectives can serve as a source of input for various purposes, which highlights PM's capacity in this regard. Not only can conclusions be drawn about the achievement of the objectives by users, but hypotheses that could not be validated or were poorly formulated at the outset can also be modified because of the new information obtained. In fact, new hypotheses can be put forward on the basis of behaviors collected in the *event logs*, which had previously not been taken into account because of a lack of knowledge.

As shown in Figure 5, the validation process of the hypotheses raised affects previous steps, such as the definition of the game events or the very conception and design of the game. This iterative and dynamic process is what allows the solution to be fine-tuned. The ultimate goal of this loop process is that, based on the information self-generated by the game, the system itself is nourished, updated, and adapted to the demands and characteristics of the player, as well as to the process of analysis of this information presented to the team of experts.

Experiment and Hypothesis

Amalia's Planet was tested twice in a school in the Community of Madrid, Spain.

Information was collected through interviews with parents about their children's medical history related to previous hearing pathologies, such as previous hearing infections (otitis, drains, and secretions) and ear surgeries, and whether their children had a diagnosis of attention-deficit/hyperactivity disorder (ADHD) or learning difficulties [32,33]. Hereafter, this group of conditions will be referred to as previous hearing pathologies.

To evaluate the achievement of the discriminating objective of the game (screening tool), the interdisciplinary team proposed the following hypotheses:

1. There is a difference in gameplay performance between children with previous hearing pathologies and children without previous hearing pathologies.

2. "Healthy" players learn faster. Children who have not had any of the aforementioned conditions are expected to improve their gameplay performance faster than children with a diagnosed pathology.
3. Children learn while they play. Regardless of whether children have had a hearing condition, it is interesting to know whether the game improves their trained skills.

To test the formulated hypotheses, a statistical study of the difference in means between the 2 groups of children (with and without previous hearing difficulties) was conducted. In addition, different scatter plots were studied with respect to measures of central tendency with the aim of finding atypical behaviors that reveal the presence of individuals at risk. These hypotheses are assessed later in this paper.

Results

Sample Summary

The sample size was determined in such a way that, according to the central limit theorem, the statistical distribution of each of the populations considered for the study (children with previous hearing pathologies, children without previous hearing pathologies, distribution of children by sex, etc) was correctly reflected in the collected data [34]. Thus, theoretically, a sample size of 50 children was determined for each sample group (n>30), with a total sample of 100 children in the study. Nevertheless, owing to the limited availability of users of interest for the study and some problems in data collection using the tool (3 players were excluded), the final size of the sample used for this study was 87 children.

The sample consisted of children of both sexes (50 female and 37 male children) aged between 5 and 14 (mean 8.87, SD 1.74; median 9) years. Most of the players (76/87, 87%) were aged between 7 and 11 years, of whom 55% (42/76) were female and 45% (34/76) were male, maintaining approximately the initial distribution of the sample.

Regarding the pathology line, without taking into account sex or age, 45% (39/87) of the players had or used to have at least 1 pathology among those contemplated in the study, resulting in 55% (48/87) of "healthy" participants. The sex ratio was as follows: 57% (50/87) female and 43% (37/87) male. Health information obtained through the parent questionnaire revealed the following classification by previously identified pathology: (1) 55% (48/87) of the sample had a history of otitis, of whom 33% (16/48) had major complications, although only 28% (24/87) had undergone a surgery for drainage; (2) 3% (3/87) were diagnosed with ADHD; and (3) a similar percentage 3% (3/87) had learning disorders.

The sample included children with a history of hearing pathologies and children without a history of hearing pathologies. Hence, focusing on the players with some previous pathology (39/87, 45%), there were 49% (19/39) of players with just 1 pathology, 31% (12/39) of players with 2 different pathologies, and 21% (8/39) of players with up to 3 types of pathologies. Overall, 92% (36/39) of the players with at least 1 pathology had or used to have otitis.

Among the 19 children with just 1 affliction, 84% (n=16) had otitis (a percentage close to the prevalence of otitis in the total population of 87 children, which is estimated at 80% [35]), and 11% (n=2) had ADHD, making it the second most frequent pathology appearing individually. Generally, suppurations and learning disorders appeared to be accompanied by at least 1 other type of pathology in all cases. The most common combination of afflictions was made up of otitis and suppurations, which was present in 11 children (55% of the players with at least 2 pathologies). In terms of sex, the percentage of female players with some kind of affliction was close to the percentage of male players with some kind of affliction: of the 50 female players, 22 (44%) had a pathology, and of the 37 male players, 17 (46%) had a pathology.

Overview of the Obtained Health Results

Results Obtained in Test 1

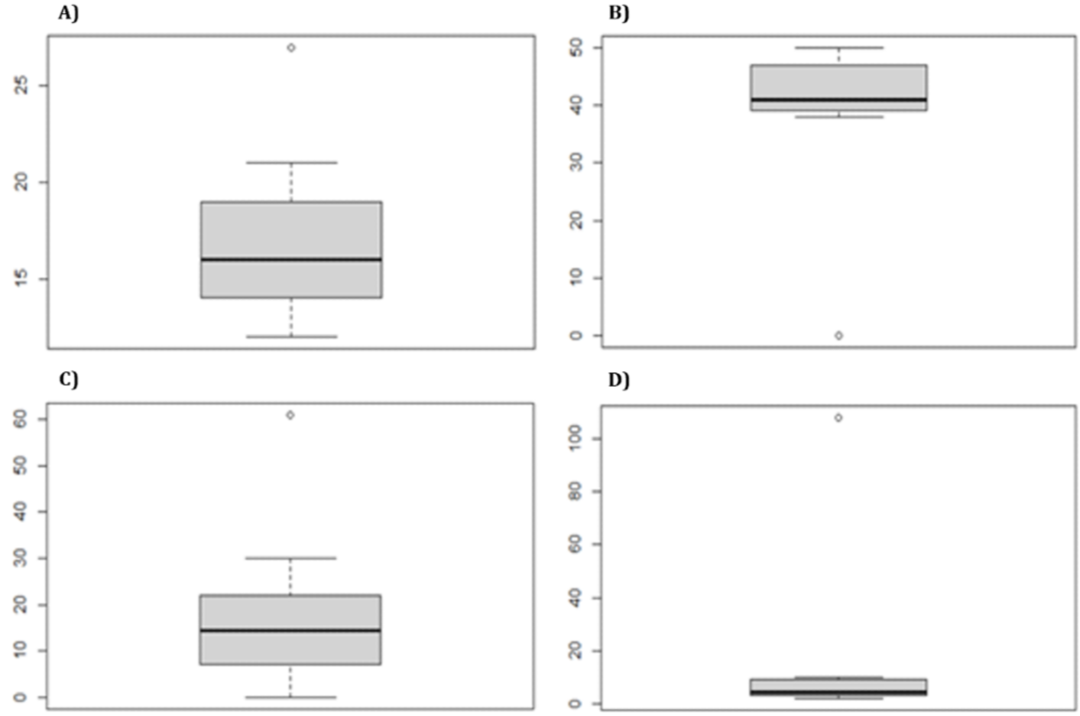
For this first test, a sample of 59 children was available. Among the 59 children, 29 (49%) had previous hearing pathologies, with a total of 14 (48%) male and 15 (52%) female children. On the other hand, a total of 51% (30/59) children were part of the group of children who were not diagnosed with hearing pathologies, with a total of 50% (15/30) male and 50% (15/30) female children.

The percentage of players with afflictions who managed to finish the game successfully was lower than the percentage of "healthy" players (11/29, 38% of players with some affliction against 16/30, 53% of "healthy" players). To determine whether this difference in the level of playing between the different groups was statistically significant, a chi-square test was performed, obtaining a *P* value of .24. Therefore, whether the child had or used to have a hearing pathology did not seem to affect their ability to successfully complete the game. However, it was interesting for the team to answer the following question: is it possible that some of the children initially classified as "healthy" players may in fact have one of the pathologies considered in the study or a different one and have not been diagnosed? Taking the following variables as references, throughout the collection of the information, it was observed that there were certain players initially cataloged as "healthy" whose level of gaming stood out compared with the level of playing of their peers:

- TOTAL_ATTEMPTS: the number of attempts the player has made throughout their game
- TOTAL_ACCURACIES: the number of successes the player has produced throughout the game
- FAILURE_TOTAL: the total number of failures the player has faced during the game
- TOTAL_SUBS: the number of sounds omitted by the player throughout the game

Figures 6A to 6D show (from left to right) the existence of players initially classified as "healthy" who, compared with their group, showed atypical behaviors in their results, particularly, the players who did not manage to pass the game, presenting a large number of errors or omissions throughout their game (ID 30 and ID 74).

Figure 6. Test 1: (A) total number of attempts for healthy players who did not complete the game, (B) total accuracies for healthy players who did not complete the game, (C) total number of failures for healthy players who did not complete the game, and (D) total number of omissions for healthy players who did not complete the game.



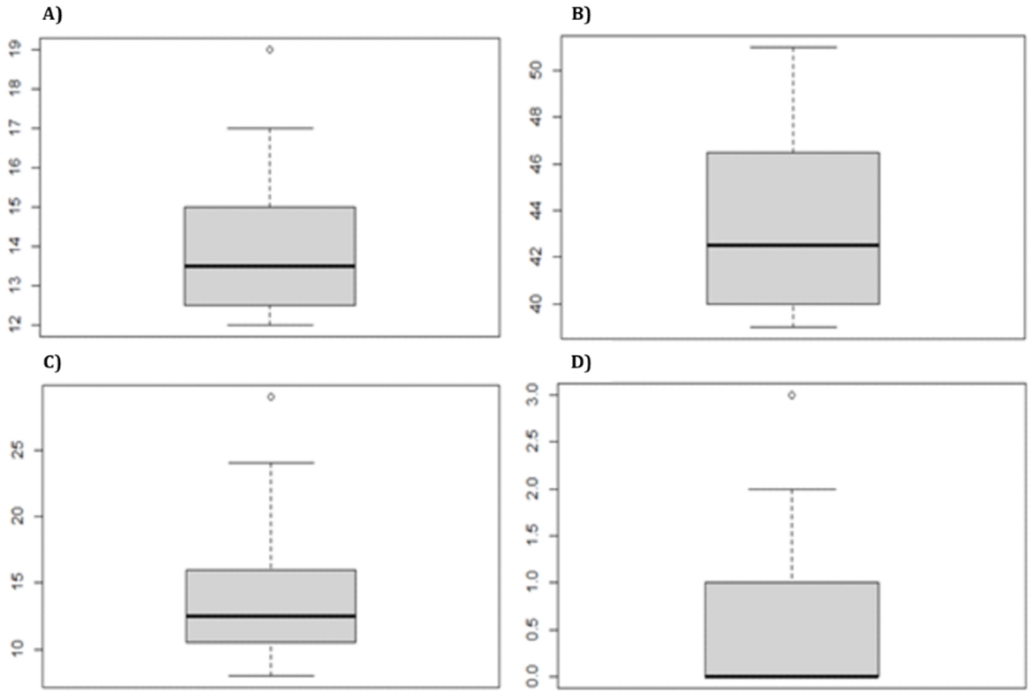
Results Obtained in Test 2

For the second test, a sample of 70 children was available. Among the 70 children, 28 (40%) had previous hearing pathologies, with a total of 13 (46%) male and 15 (54%) female children. On the other hand, a total of 60% (42/70) children were part of the group of children who were not diagnosed with hearing pathologies, with a total of 45% (19/42) male and 55% (21/42) female children.

In this second test, most players managed to pass all the levels of the game. There was a clear difference between the percentage of children with previous pathologies who managed to finish the game completely and the percentage of children without previous pathologies who managed to finish the game completely (26/42, 62% of the players without pathology against 12/28, 40% of the players with some type of diagnosed pathology). To determine whether this difference was statistically significant, a chi-square test was performed, obtaining a *P* value of .19. Therefore, at a confidence level of 80%, there was no statistical evidence to reject the hypothesis that having the afflictions in question affects the ability to complete the game successfully.

To determine whether the players who stood out in test 1 maintained the trend in the second test, the variables mentioned earlier were analyzed again to study their distribution in the sample. Figure 7 shows that these players maintained the same tendencies along the second trial.

Figure 7. Test 2: (A) total number of attempts for healthy players who did not complete the game, (B) total accuracies for "healthy" players who did not complete the game, (C) total number of failures for healthy players who did not complete the game, and (D) total number of omissions for healthy players who did not complete the game.



Overview of the Obtained Game Validation Results

As noted earlier, the achievement of the test objectives should not be the only measure of the test's fitness for purpose, but aspects such as the time required to pass each of the tasks and the different event traces constituted by each player can be sources of information to be considered. To this end, the team used the ProM (Prom Software Inc) software, which is an extensible framework that supports a wide variety of PM techniques in the form of plug-ins [27]. By evaluating the different event logs defined in the previous stages, the abovementioned features can be evaluated and, if necessary, modified further by adapting the tool to its final objective.

Figure 8 depicts the duration of each of the events that were defined in the initial stage. Based on the understanding that the duration of an event is the time that elapses from the time when the "faster" player initializes it until the time when the "slower" player finishes it, this graph can reveal the existence of events that pose a greater challenge to the individual. To avoid the feeling of frustration that the player may experience, and the consequent decrease in performance, this particular feature of PM techniques allows the team to modify such game events.

Figure 8. Duration of events.

Furthermore, the study of event traces and the frequency with which they appear in the collected sample serves as a mirror of the correct functioning of the game (Figure 9). Thus, it is possible to detect structural faults in the tool, such as jumps between levels that are not consecutive, backtracking that is not allowed, and advancing to a new level without having completed the previous one. All these constituent faults can be corrected by the technical part of the development team, ensuring the correct functioning of the tool in future tests.

Finally, another graph of interest that can be obtained using the ProM software is the so-called Business Process Model Notation [27]. This graph provides information about the route that different players followed to pass the game, identifying the main events that each player went through. Furthermore, loops and cycles can be detected using this graph; thus, the team can deduce the possible learning resources of the players (Figure 10).

Figure 9. Obtained traces and their frequency.

Discussion

Principal Findings

SGs are increasingly being used as support tools for the development and improvement of skills in individuals of different age ranges in areas such as education and health. In addition, it is nowadays demonstrated that an early diagnosis of CAPD in an individual is a desirable characteristic from the point of view of the consequent therapeutic process [36]. In other words, school-age children who are screened for CAPD may benefit greatly from the treatment of CAPD symptoms. Despite this, it is currently not possible to find a tool that brings together these 2 ideologies to minimize, or even eliminate, the afflictions that this disorder causes in those who have it.

On the basis of the conception and development of an SG, Amalia's Planet, and its use in a real school environment, the research team was able to contrast the different hypotheses put forward in previous sections regarding the suitability of the use of SGs as screening tools for CAPD. More specifically, this study showed that once the users become familiar with the game and its rules, users who were affected by auditory pathologies related to the disorder in question perform less well on the tasks they are given. More specifically, at a confidence level of 80%, there was no statistical evidence to reject the hypothesis that there is a difference in gameplay performance between children with hearing pathologies and children without hearing pathologies. That is, the fact that the player had any of the pathologies considered in this study directly affects their performance in the game. Moreover, the abovementioned statement only supports the hypothesis that "healthy" children learn faster than children with a diagnosis. Finally, an improvement in the performance of the players could be observed when comparing their performance in test 1 with that in test 2.

One of the main results obtained in this study is that using the proposed solution, the team was able to detect the presence of 2 users who were initially assigned to the group of "healthy" individuals owing to the lack of diagnosis but who presented a gameplay performance more similar to that of the group of at-risk individuals. Such an outcome allows family members, educators, and health professionals to pay more acute attention to these users. Such children can then be examined to determine whether their performance was altered by the presence of an auditory processing pathology or by other external factors.

At this point, it is worth highlighting the fact that if, using traditional statistical techniques on extreme values, both users were eliminated from the sample, and the data were reanalyzed, the results obtained would have been even more discriminant. For both tests 1 and 2, with statistical confidence levels of 85% and 95%, respectively, there would have been no statistical evidence to reject the hypothesis about the difference in performance between "healthy" players and those who had been diagnosed.

In turn, the use of PM techniques as a tool for evaluating the suitability of the solution to the problem posed allowed the team to develop different methods for improving the game. In particular, by studying the duration of the game events, the team detected some phases of the game that can generate frustration in the players, thus reducing their level of attention and, consequently, their performance. In addition, different learning resources used by the players were detected. By studying cycles and loops along the player's traces, learning resources based on failure and omission that were used by the player to subsequently complete the levels could be detected. Finally, the team was able to detect jumps between nonconsecutive levels of the game. All these features to be improved in the tool could be addressed in future versions, thanks to the validation of the proposed solution through PM techniques.

Limitations of the Study and Future Works

After testing the developed tool, the team was able to detect a series of aspects to improve in the application. First, at the time of data analysis, a lack of information was detected from a total of 3 users. This lack of information due to an error in the deployment of the solution led to the exclusion of these players from the final analysis. Moreover, in the first game in which the child has to find the baby penguin, a bug was detected. Here, some players had to cross a bridge to reach their goal. However, some of them fell from the bridge into the water and required the help of adults to continue, adding time to their markers and lowering their score. Moreover, thanks to the use of PM tools, events in which the dynamic followed in the game was not established could be detected a priori. Thus, in Figure 10, a jump from the initial event to the final event without going through any intermediate states can be detected. In addition, in other cases, player games were detected in which the game "jumps" from one level to another, ignoring intermediate sublevels.

Finally, events that were "excessively" long compared with others were detected. These events will have to be reviewed, as they can suppose a defective performance on the part of the tool or a high level of complexity for the players involved.

In addition to the revision and correction of the mentioned errors, the team of authors is currently developing new "habitats" for the Amalia's Planet ecosystem, which covers new aspects related to CAPD screening and were not included in this first version.

Conclusions

CAPD is a disorder that is difficult to detect during childhood, and its early detection is a challenge to be solved in the near future using quick and easy-to-apply screening tools. To our knowledge, this is the first study that unifies the ideology of a screening test for CAPD in school-age children and the use of SGs to support the diagnosis and consequent treatment of CAPD. Despite the need for further testing of the usability of the tool and the improvement of certain functional aspects of the tool, the development team was able to obtain results with statistical evidence that support the use of Amalia's Planet as a screening tool for children at risk for CAPD. Amalia's Planet can be expanded to include games that assess other forms of afflictions experienced by children with the disorder under study.

Acknowledgments

The authors would like to thank the team of nursery and primary teachers at the Colegio de Amanecer (Madrid, Spain) for their collaboration in performing the experiment presented here.

Abstract

Background: Depression is a debilitating mental health disorder, with a large treatment gap. Recent years have seen a surge in digital interventions to bridge this treatment gap. Most of these interventions are based on computerized cognitive behavioral therapy. Despite the efficacy of computerized cognitive behavioral therapy–based interventions, their uptake is low and dropout rates are high. Cognitive bias modification (CBM) paradigms provide a complementary approach to digital interventions for depression. However, interventions based on CBM paradigms have been reported to be repetitive and boring.

Objective: In this paper, we described the conceptualization, design, and acceptability of serious games based on CBM paradigms and the learned helplessness paradigm.

Methods: We searched the literature for CBM paradigms that were shown to be effective in reducing depressive symptoms. For each of the CBM paradigms, we ideated how to create a game so that the gameplay was engaging while the active therapeutic component remained unchanged.

Results: We developed 5 serious games based on the CBM paradigms and the learned helplessness paradigm. The games include various core elements of gamification, such as goals, challenges, feedback, rewards, progress, and fun. Overall, the games received positive acceptability ratings from 15 users.

Conclusions: These games may help improve the effectiveness and engagement levels of computerized interventions for depression.

Introduction

Background

Depressive disorders are a leading cause of disability worldwide, affecting >264 million people [1]. Antidepressant medications and cognitive behavioral therapy (CBT) are currently the most effective treatment modalities for depression [2-4], but there is a large treatment gap owing to the lack of accessibility, high cost of therapy, and social stigma associated with the visits to a psychiatric clinic [5-7]. In the past 2 decades, digital interventions have been gaining traction. The most widely studied digital intervention for depression is computerized CBT (cCBT). Although cCBT is an effective form of treatment [8-10], a recent meta-analysis has demonstrated that guided cCBT is less acceptable than being on a waiting list [11]. There is a need for other digital treatment modalities.

The cognitive theory of depression posits that information processing—attention, interpretation, and memory—is negatively biased in depression [12,13]. This biased information processing has been implicated in the onset and maintenance of depression [14]. Experimental studies have corroborated the cognitive model by providing empirical support for self-referential information processing, attention bias, interpretation bias, and memory bias [15-19]. Psychological training paradigms, known as cognitive bias modification (CBM) paradigms, have been used to modify these cognitive biases in subthreshold, clinical, and remitted populations [20-28], albeit with mixed results. Despite the mixed results and small effect sizes [29,30], this field promises novel treatment approaches and warrants further research.

The previously mentioned evaluations of CBM paradigms have been mostly performed in laboratory settings; these paradigms have received much less attention than cCBT as a potential treatment approach for depression outside the laboratory [31-33]. CBM paradigms tend to have low user engagement owing to the repetitiveness of the paradigms [34-37] and a lack of credibility in some cases [34,38]. In a digital intervention, in which the user needs to engage with a paradigm without any external supervision, the paradigm's ability to engage becomes the determining factor for the success of the intervention.

One way to make the CBM paradigms more engaging to users is by developing serious games based on the paradigms [39]. A game serves as an interactive medium that provides game designers with considerable control in creating engaging experiences and can reduce the attrition rate in digital interventions [40]. Serious games have been evaluated for multiple conditions, including posttraumatic stress disorder [41,42], autism spectrum disorder [43-45], attention-deficit/hyperactivity disorder [46], cognitive functioning [47,48], alcohol use disorder [49,50], trait anxiety [51,52], etc. The results of a meta-analysis that evaluated the effectiveness of serious games demonstrated a moderate effect size of serious games for reducing psychiatric disorder–related symptoms compared with no intervention controls [53]. In a review of 4 studies that evaluated CBM interventions based on serious games, only 2 studies reported their gamified interventions to be effective [54].

Serious games have been developed for various aspects of depression. Bespoke serious games have been created to diagnose depression [55,56], treat depression [57-63], and describe the experience of depression either metaphorically [64] or literally [65]. Off-the-shelf commercial games have also been used to target depression [66]. There are multiple serious games based on different therapeutic techniques—CBT [67-69], solution-focused therapy [70], and interpersonal therapy [68]—that do not target depression specifically but can be useful. There is only 1 serious game based on a CBM paradigm targeting depression, but it was found to be ineffective [62]. Serious game–based interventions have been shown to be acceptable to the users overall [57,60,67-69]. A recent review, however, suggests that the effectiveness and acceptability data are not convincing enough yet to warrant clinical adoption [71].

Objective

In this study, we selected specific CBM paradigms that had received empirical support for targeting cognitive biases underlying depression and appeared suitable for conversion to games. Then, we described the design and development of these games in detail. Furthermore, we developed 1 serious game based on the learned helplessness theory.

Methods

Embedding Training Paradigms Into Serious Games

We searched the literature for known CBM paradigms and selected those that have shown promise in reducing depressive symptoms and were amenable to conversion to games. Our team discussed multiple game ideas for each paradigm. While thinking of the ideas, the primary aim was to make the gameplay engaging while keeping the active therapeutic component unchanged. After multiple sessions on ideations, the team selected the most promising game idea for each paradigm. Once the team agreed on a game idea, minimally viable prototypes were created and tested within the team. These minimally viable prototypes were improved upon to create the final versions by using the feedback obtained from informal tests performed in a larger group of approximately 10 friends and colleagues.

Software Development

We used Angular 8 (Google LLC) and JavaScript (ECMAScript 2018) for creating the front end of the games and Django-rest-framework 3.9.2 (Encode OSS Ltd) and Django 2.2 (Django Software Foundation) for creating the backend of the games. Two games required the detection of the swipe gesture on the screen, for which we used a readily available library, *hammer.js*. For 1 game that required the simulation of gravity and collision in the game environment, we used the *phaser.js* framework. The games were optimized for smartphone screens and were also compatible with tablets, laptops, and desktop devices. We created the graphical elements required for the game using Adobe Illustrator (Adobe Inc). Musical elements required for some of the games were collected from open web resources. The *negative attention bias training game* required the combination of 20 rhymes (Rock a bye baby, Wheels on the bus, etc) and famous compositions (Ode to joy, Für Elise, etc). The musical notations for these rhymes and compositions were collected from various YouTube channels. A few of them were readily available in the scientific pitch notation. For the others, we deduced the musical notations from the simple piano versions of these rhymes and compositions available on YouTube.

Feedback on the Games

To obtain a preliminary sense of the acceptability of the games, we asked 15 pilot users (n=8, 53% male and n=7, 47% female) to provide feedback on the 3 aspects of the games. The users were recruited from the Indian Institute of Technology, Kanpur community, by word of mouth. Potential users who expressed interest were sent an email detailing the procedure to participate in the study and to provide feedback. They were also sent an informed consent form via email. They were required to include their name and signature in the informed consent form and email it back to the study team. These users rated the games on three aspects: (1) *The instructions on how to play the game were clear*, (2) *The game was fun to play*, and (3) *The purpose of the game was clear*. The users rated these aspects on a 5-point scale—(1) strongly agree, (2) agree, (3) neutral, (4) disagree, and (5) strongly disagree. These ratings were mapped to scores of 2, 1, 0, −1, and −2, respectively. For the game for learned helplessness, we asked the users an additional question, *In this game, you were presented with some unsolvable puzzles and some solvable puzzles. After you completed the game, the logic of the game was presented to you. After playing the game and reading the explanations, which of the following statements are true (tick all that apply)*?

The following options were provided: (1) *I have an understanding of learned helplessness*; (2) *I felt angry or frustrated while I was stuck with the puzzles*; (3) *After the logic of the game was explained, my frustration or anger reduced*; and (4) *After the logic of the game was explained, my frustration or anger did not reduce*. The feedback was collected as a preliminary pilot for a larger study.

Ethics Approval

Ethical clearance was provided by the Institutional Ethics Committee of the Indian Institute of Technology Kanpur (IITK/IEC/2019-20/II/4).

Analysis

We calculated the average value of the feedback received on the different aspects of the game. We also checked whether the feedback received was significantly different from 0 using the Wilcoxon signed rank test. Python (version 3.10.5; Python Software Foundation) and MATLAB R2020b (Mathworks) were used for data analysis.

Results

Design Philosophy

Our main design objectives were to make the games effective by using evidence-based paradigms and engaging by incorporating 6 out of the 7 core elements of gamification. The evidence-based paradigm used for the individual games is described in individual sections throughout the paper. CBM paradigms have been reported to be boring and repetitive [34-37]. We hypothesized that making the games fun and engaging would increase the likelihood of spontaneous gameplay and, consequently, increase the CBM dosage without external supervision. Studies have reported that the rationale behind some CBM interventions is not apparent to the users, which can contribute to the lack of engagement [34,38]. To tackle this, we added a brief section called *Science behind the game* to each game.

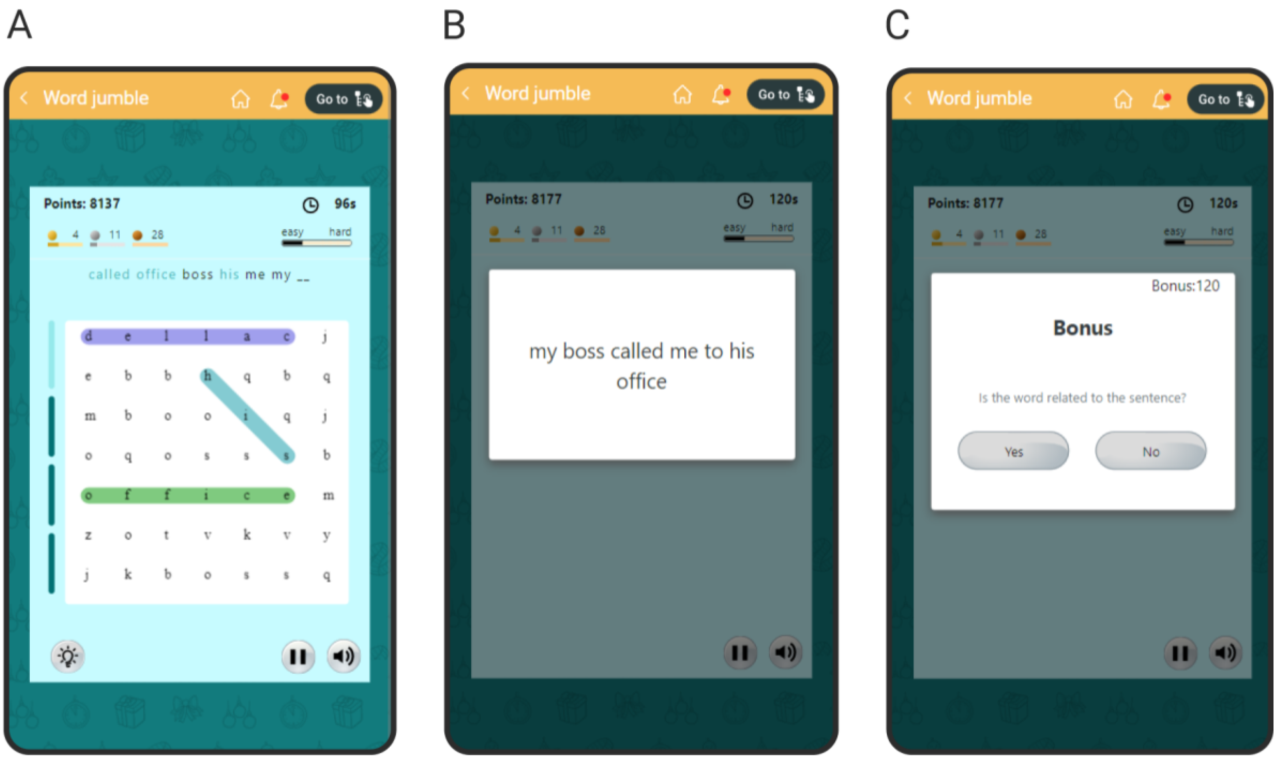
Individuals experiencing an episode of depression have decreased cognitive abilities [72]. Considering this, we designed the gameplay to be easy and intuitive, such that anyone with some experience in using smartphone apps and a basic familiarity with the English language could play the games. We also kept the hardware requirements for the games minimal so that they could be played on low-end smartphones. At the beginning of the games, we gave simple in-game instructions or in-game tutorials. To avoid an artificial limit on the practice of CBM, we designed the games to be never-ending (except for the game for learned helplessness, in which the design required a definite ending). The difficulty level of each game adapted to the skill level of the user to create the *flow* experience [73]. Apart from making the games intrinsically engaging, we also added some extrinsic motivators to play the games, such as badges and scores, or the sensory experience of a familiar musical tune. The badges served as short-term rewards for playing the games, and the scores served as in-game currency, which could be exchanged for lives or hints in the games. We describe how our games are based on the elements of gamification in the later section titled, *How game-like are our games?*

Game for Automatic Interpretation Bias Modification

People with depression have an automatic negative interpretation bias [74]. Cowden Hindash et al [21,75,76] used a modified word sentence association paradigm for participants with dysphoria to confirm and modify the automatic negative interpretation bias. The bias modification paradigm also showed a near-transfer effect on the Scrambled Sentence Task [77] and a far-transfer effect of increased resiliency on a laboratory stressor [21].

In the task of modified word sentence association paradigm for participants with dysphoria, a self-relevant ambiguous sentence (*My mom called me to tell me the news*) is shown for a short duration, followed by a positive or negative word. The user is asked whether the word is related to the sentence. The user can answer *Yes* (related) or *No* (unrelated). The user is trained, via text-based feedback, to associate positive words with ambiguous sentences; the feedback is *Correct* if the answer is *Yes* for a positive word or *No* for a negative word; otherwise, the feedback is *Incorrect*. We converted this paradigm into a serious game in the following manner: The game displays an alphabet grid. The user's goal is to find the words (that can be formed by connecting letters in the grid; Figure 1A) that form the ambiguous sentence. The game screen includes several empty bars, equal to the number of words to be found. As the user finds a word, a bar gets filled to provide the users with a sense of progress in the game and indicate the number of words found. Once the user finds 50% of the words, we reveal the full ambiguous sentence (Figure 1B), and then we show a positive or negative word and ask the user if the word and the sentence are related (Figure 1C). The user can answer by clicking on *Yes* (related) or *No* (unrelated) buttons. Quicker answers are given higher rewards to encourage the users to answer with the first thought they have. An incorrect answer receives 0 points. To prevent the users from clicking *Yes* for all positive words and *No* for all negative words, we used decoy sentence-word pairs, in which the sentence was unambiguous, and the negative word was related, while the positive word was unrelated [78].

Figure 1. Screenshots of the game for automatic interpretation bias modification. (A) The user finds words that are contained in the sentence by linearly connecting letters in the grid. (B) The ambiguous sentence is shown in full once the user finds 4 words. (C) The user is asked if the word (*Bonus* in the shown example) is related to the sentence on the previous screen.



The users earn reward points by finding words in the grid. Valid English words that are not parts of the sentence also earn points. The points, apart from being a short-term reward, also serve as an in-game currency to buy extra time or hints. Apart from points, the users also receive other short-term rewards in the form of bronze, silver, and gold badges for completing 4, 10, and 26 levels, respectively.

The game adapts to the user's level of competence by varying the number of words hidden and allotted time per difficulty level (Figure S1 in Multimedia Appendix 1). To help the user in learning to play the game, the initial 4 levels of the game keep the words of the sentence fully visible in a jumbled order and give the user 150 seconds (in the first 2 levels) or 120 seconds (in the next 2 levels) to find the words in the grid. A bar, ranging from *Easy* to *Hard*, indicates the game's current difficulty level.

There are 42 levels (sentence-word pairs) in the game. The difficulty of each level depends on the number of words to be found and the complexity of the grid. These, in turn, depend on the length of the sentence and the length of the longest word. The levels are arranged to gradually increase the difficulty level. After the completion of all the levels, the game loops back to the first level.

Game for Executive Control Training

Rumination, a core factor in depression, affects the duration [79] and intensity [80] of depressive episodes. Multiple studies have established that depressive rumination is associated with an inability to inhibit the processing of emotional information [81,82]. Executive control is one mechanism that regulates the ability to inhibit emotional information in healthy individuals [83-85]. Cohen et al [86] hypothesized that the difficulty in using executive control might be the factor behind impaired inhibition in ruminators. Cohen et al [86] designed a paradigm to train individuals to exert executive control before exposure to an emotional stimulus, followed by a discrimination task. They observed that individuals trained with this paradigm were less likely to engage in a state of rumination [86] and more likely to use reappraisal—an effective emotion regulation technique—more frequently and efficiently [87]. On the basis of this executive control training paradigm [87], we designed a 2D platform game to resemble the classic video game, Super Mario Bros. (Figure 2). The goal of the user is to keep a running avatar alive by jumping over obstacles (sitting or jumping frogs; Figure 2A) or pits (Figure 2B). The pits are of different types: some requiring a single jump, some requiring a double jump, and some including floating platforms in between (Figure 2C). The floating platforms are also of 2 kinds—some are stationary when the avatar lands on them, whereas others start to fall upon the landing of the avatar. The avatar sometimes passes through an underground tunnel, and on returning to the ground level, the background landscape changes to maintain a diversity of visuals. An in-game tutorial is shown to make the user familiar with the game's rules and controls. On a keyboard-based device, the arrow keys can be used to play the game. On a touchscreen device, buttons corresponding to the arrow keys are shown on the screen itself.

Figure 2. Screenshots of the game for executive control training. (A) The avatar faces an obstacle, a jumping frog. (B) The avatar faces an obstacle, a pit. (C) The avatar faces a longer pit with floating platforms. (D) The instructions for the cognitive bias modification paradigm. (E) An incongruent flanker task as a part of the cognitive bias modification paradigm. The user must press the button corresponding to the middle arrow in the flanker task. (F) A green circle as a part of the cognitive bias modification paradigm. The user must press the button (green button on the right side) corresponding to the circle in the center.

As time progresses, the speed of the avatar increases to increase the difficulty level. The score in the game increases over time as the avatar continues to run. Intermittently, the game screen presents coins, which can be collected by jumping. The coins serve as an in-game currency. Initially, the user is given 3 lives and 5 double jumps for free. Once the user exhausts the free double jumps, each double jump costs 10 coins. In addition, once the user exhausts the free lives, additional lives can be purchased with coins with gradually increasing difficulty: the first purchase costs 10 coins and each purchase after that costs twice the amount of the last purchase.

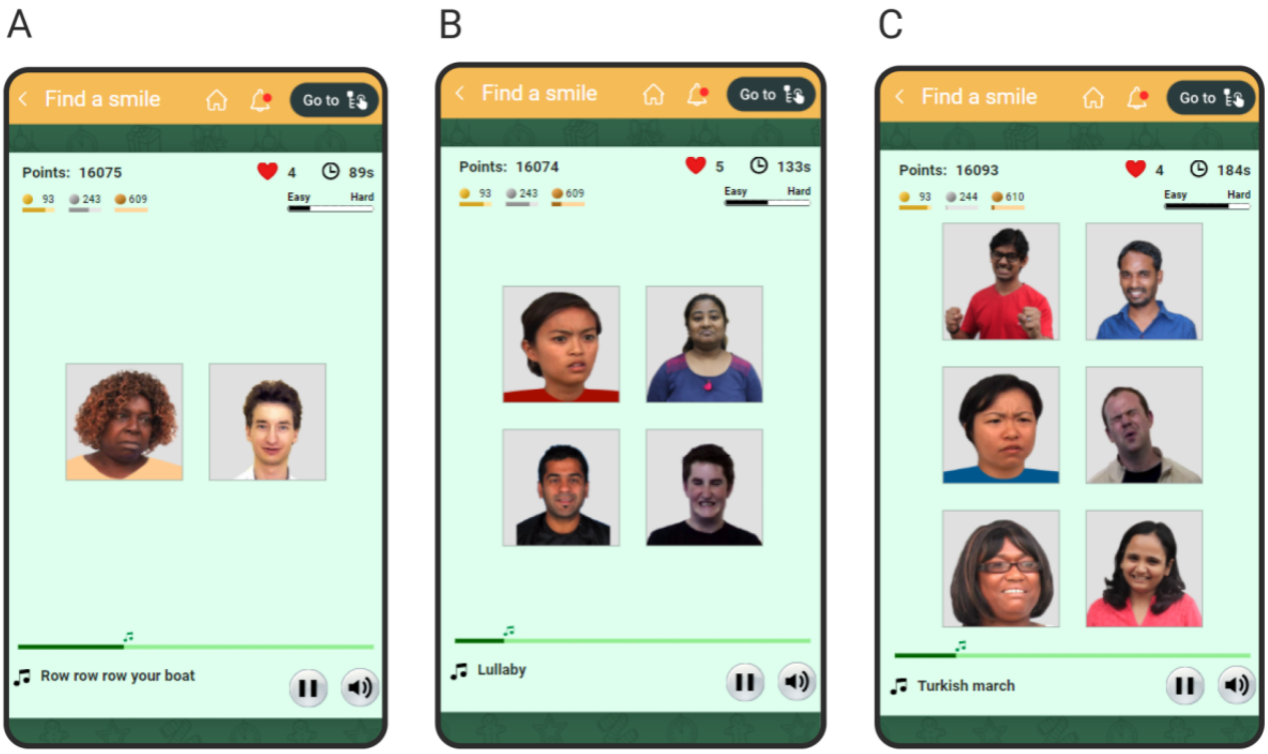
At predetermined points in the game, the avatar stops in front of a large pit with floating platforms. At this point, the executive control training task is shown to the user (Figure 2D). An incongruent or a congruent set of flanker arrows (Figure 2E) is shown with a 50:50 probability. The user is required to press an arrow key corresponding to the middle arrow in the set. The flanker arrows remain visible until the user responds or for a maximum of 1000 milliseconds. After the flanker set disappears, an image is shown for 100 milliseconds. The image is neutral or negative with an 80:20 probability following a congruent set and with a 20:80 probability following an incongruent set. After a further gap of 50 milliseconds, during which no stimulus is shown, a green or red circle is shown with a 50:50 probability (Figure 2F). The user is required to respond according to the color of the circle (up arrow for green and down arrow for red). The circle remains visible until the user responds or for a maximum of 2000 milliseconds (Figure S2 in Multimedia Appendix 1). These 3 steps—including the arrows, the image, and the circle—constitute 1 round of training. The next round of similar training steps begins after a delay of 2000 milliseconds. After 3 rounds of training, the gameplay begins again and continues for approximately 30 seconds before the next batch of training begins. The instructions for choosing the correct keys are shown before each round of training. If the user presses the correct keys for both the flanker task and the colored circle task in a round, it is considered a correct response. The users are incentivized to perform the task diligently, as correct choices reward them with double jumps or additional lives. The users can also earn short-term rewards in the form of bronze, silver, and gold badges for 6, 15, and 39 correct responses, respectively.

Game for Negative Attention Bias Modification

The vulnerability model of low self-esteem and depression states that low self-esteem increases the risk of future depressive episodes [88,89]. Accordingly, improving one's self-esteem should reduce the risk of depression. Individuals with lower self-esteem are more attentive to rejection cues, which in turn increases their tendency to interpret more and more social cues as rejecting, thus perpetuating the cycle of vigilance and low self-esteem [90,91]. Dandeneau et al [92] used an attention-training paradigm to modify this negative attention bias and observed that it led to a more resilient self-esteem against a laboratory-based rejection manipulation.

We designed a game based on the same training paradigm to overcome negative attention bias [92]. Images of human faces, one depicting a positive emotion and the others depicting negative emotions, are shown in a grid (Figure 3). The user is asked to click (or tap, when played on a touchscreen device) on the image with positive emotion as quickly as possible. Once the user clicks on the positive image, the next set of images is displayed in the same grid. To make this process fun and engaging, the game plays a musical note when the user clicks on a positive image. The musical notes, played sequentially, are taken from a popular song (or rhyme), and 1 song constitutes 1 level of the game. A click on a negative image results in an unpleasant beep. Therefore, in effect, the user can play the song by clicking on the faces with positive emotions—the more accurately they select the images with positive emotions, the fewer interruptions they hear during the song.

Figure 3. Screenshots of the game for negative attention bias training, showing (A) a 1 × 2 grid, (B) a 2 × 2 grid, and (C) a 3 × 2 grid of faces with different emotions.



To make the game challenging, the user is given a time limit to finish each level, calculated as $TT = N \times T$, where N is the number of musical notes in the song and T is the time allotted per note (initialized to 5000 milliseconds). The game adapts to the user's performance level by dynamically varying T between 1000 and 5000 milliseconds and the grid size between 1 × 2 (Figure 3A), 2 × 2 (Figure 3B), and 3 × 2 (Figure 3C) after the completion of each level. The algorithm of this adaptation is summarized in Figure S3 in Multimedia Appendix 1.

A bar, ranging from *Easy* to *Hard*, indicates the current difficulty level. To dissuade the user from clicking on images without paying attention, we penalize each click on a negative image by deducting 1 life (in addition to playing the unpleasant beeps). The user is given 5 free lives at the beginning of each game. Once the user runs out of lives, they have the option to replay the same level. Clicks on positive images earn points, which can be used to buy more time if the user runs out of time before the completion of a song. To give the user a sense of progress at each level, a progress bar on the screen indicates the fraction of notes in the current song that has been played.

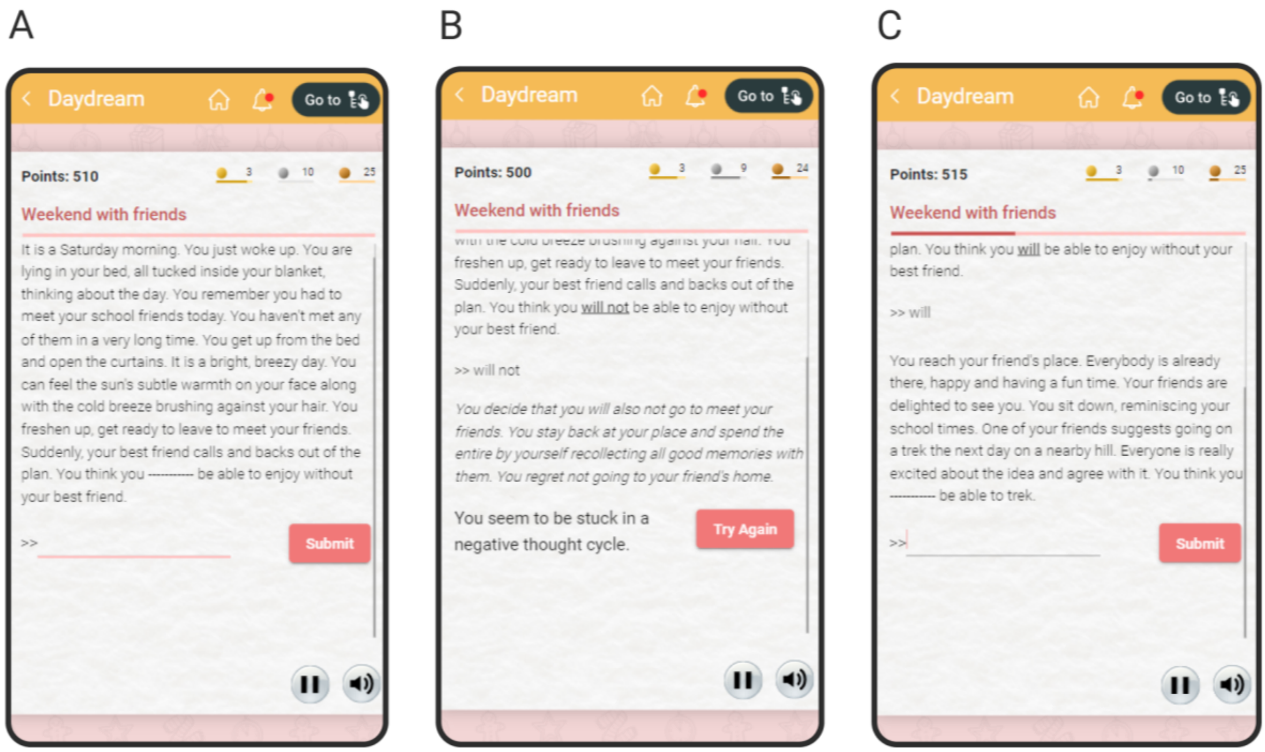
The users also receive badges as short-term rewards. They earn bronze, silver, and gold badges by clicking on 34, 60, and 156 positive images, respectively. The game has 20 levels (songs). Once the user finishes all the songs, the game loops back to the first song.

Game for Positive Imagery Training

Negative automatic thoughts can be verbal or imaginal [93]. Holmes et al [94] developed an interpretation bias training paradigm based on positive mental imagery. Multiple studies have demonstrated that the training has a positive effect on the participants' moods [25,94-96], although there are some exceptions [36,97]; the training also helped in targeting anhedonia [97].

We designed a serious game based on the combination of paradigms by Holmes et al [94] and Mathews and Mackintosh [98]. This game was developed as interactive fiction inspired by Zork [99]. At each level, the user is presented with an ambiguous scenario in the form of a paragraph with a blank space (Figure 4A). The user can fill in the blank with one or more words to resolve the sentence positively or negatively (eg, *You think you ______ be able to enjoy the meeting* can be resolved positively by adding *will* or negatively by adding *will not*). The game evaluates the phrase written by the user by comparing it against a comprehensive list of possible positive and negative completions for each sentence (occasionally, if the phrase falls outside the list, the game responds that it could not understand the input and requests the user to write a different phrase). If the user resolves the sentence negatively, it is considered an incorrect response and the user is asked to try again (Figure 4B). If resolved positively, the game moves forward and another ambiguous scenario appears in continuation with the previous one (Figure 4C). Once the user resolves the second part of the ambiguous scenario positively, the level concludes and a new scenario appears at the next level of the game. As vivid imagination is an active element [100], users are urged to imagine the situations vividly in the first person. No hints are provided in the game; however, if the user fails to answer correctly in 3 attempts, a list of potential answers is shown from which the user can select one. To encourage vivid imagination, we did not include a time limit in this game.

Figure 4. Screenshots of the game for positive imagery training. (A) A scenario is shown that can be resolved positively or negatively by providing one or more words to fill in the blank. (B) If the user resolves the scenario negatively, they are asked to try again. (C) If the user resolves the scenario positively, the game moves forward and another scenario is presented.



The game is designed to be never-ending. It includes 20 levels, and after the completion of all the levels, the game loops back to the first level. The user earns 5 points for resolving a scenario positively. The user also earns a bronze, a silver, and a gold badge after positively resolving 4, 10, and 26 scenarios, respectively.

Game for Learned Helplessness

Learned helplessness is a laboratory model of depression that emulates multiple aspects of clinical depression in animals [101,102]. The state of learned helplessness, reached after some experiences of inescapable aversive conditions, involves a generalized self-assumption of powerlessness, thereby reducing the effort to come out of difficult situations in the future. A reformulation of the theory in terms of attribution theory has also been extended to humans: individuals with learned helplessness attribute their failures to personal, pervasive, and persistent lack of abilities and their successes to luck [103].

We designed a puzzle-based game to help the users understand the ideas of learned helplessness and attribution style. We reasoned that an explanation after a game-based transient experience of the phenomenon would be more effective than simply explaining the concept using text or videos and is more likely to help users change their self-defeating attribution bias.

In the original experiments on learned helplessness, dogs failed to escape avoidable shocks after they had unsuccessfully tried to escape unavoidable shocks [104]. Very recently, a paradigm has been proposed to test learned helplessness in humans using loud audio tones as a stressor [105]. To allow the users to appreciate this phenomenon without a physical stressor, we devised the following approach: if a user can solve a puzzle initially but gives up on the same puzzle when it is shown after the failure to solve a hard and unrelated puzzle, the user would be able to see the parallel with learned helplessness and realize that it can happen in real life. At this point, the user is more likely to be receptive to the introspection of their own attribution bias.

We created a suite of 4 puzzle-based mini-games to achieve this objective. The first one, the circle-triangle mini-game, is a genuine puzzle game with multiple difficulty levels. The other 3 mini-games are designed to trick the user: each of them appears like a genuine puzzle game with easy puzzles in the first 1 or 2 levels but has unsolvable levels thereafter.

The user starts by playing the circle-triangle mini-game. The screen presents a pattern of squares, each containing a circle or a triangle (Figure 5A). If the user clicks on one of the squares, it flips (a circle becomes a triangle and vice versa). Simultaneously, the adjacent squares also flip (Figure 5B). The goal of the user is to change all the embedded shapes into circles. Once the user solves the puzzle, a message (*Great*) and auditory feedback (a pleasant *ding*) are provided to the user. Next, a harder level of the same mini-game is presented. This stepwise increase in the level continues until the user fails to solve the current level and clicks on a button labeled *I give up* (Figure 5C). When this happens, 1 of the 3 unsolvable mini-games is displayed to the user.

The 3 unsolvable mini-games are based on different types of puzzles (Figures 6A-C). For example, one is based on the popular *15 puzzle*, in which a 4 × 4 grid has 1 empty cell and 15 cells containing tiles numbered 1 to 15 and the goal is to move the tiles to arrange them in increasing order. The first level shown in the mini-game is kept very simple and easily solvable (Figure 6A1), which allows the users to become familiar with the puzzle. However, unbeknownst to the user, the second and third levels are unsolvable—we set the initial configuration of tiles in these levels by slightly reordering the tiles from solvable puzzles in such a way that they could not be solved anymore but looked normal otherwise (Figure 6A2). Thus, at the second level—just after the very easy first level—the user finds it impossible to solve the puzzle and has no choice but to accept failure by clicking on the button *I give up*. After this, the third level of the same mini-game appears, in which the user again gives up regardless of how hard they try.

Once the user gives up in both the levels of an unsolvable mini-game, the last solved level of the circle-triangle mini-game is shown again (Figure 7 presents the flow of mini-games). If the user gives up on this level, which they have previously solved, we take the opportunity to draw a parallel with learned helplessness and the game ends with the explanation. By relating to the game, we explain the ideas of learned helplessness and attribution bias, with an emphasis on personalization and pervasiveness. We expect that once individuals can appreciate their own susceptibility, they are more likely to engage in the introspection to identify real-life situations where they fall prey to dysfunctional attribution styles. A correct understanding helps one to evaluate each situation independently and not lose motivation in all areas of life upon experiencing failure in some.

Figure 5. Screenshots of the circle-triangle mini-game in the game for learned helplessness. (A) The initial state in level 4. (B) An intermediate state in level 4. (C) An intermediate state in level 6.

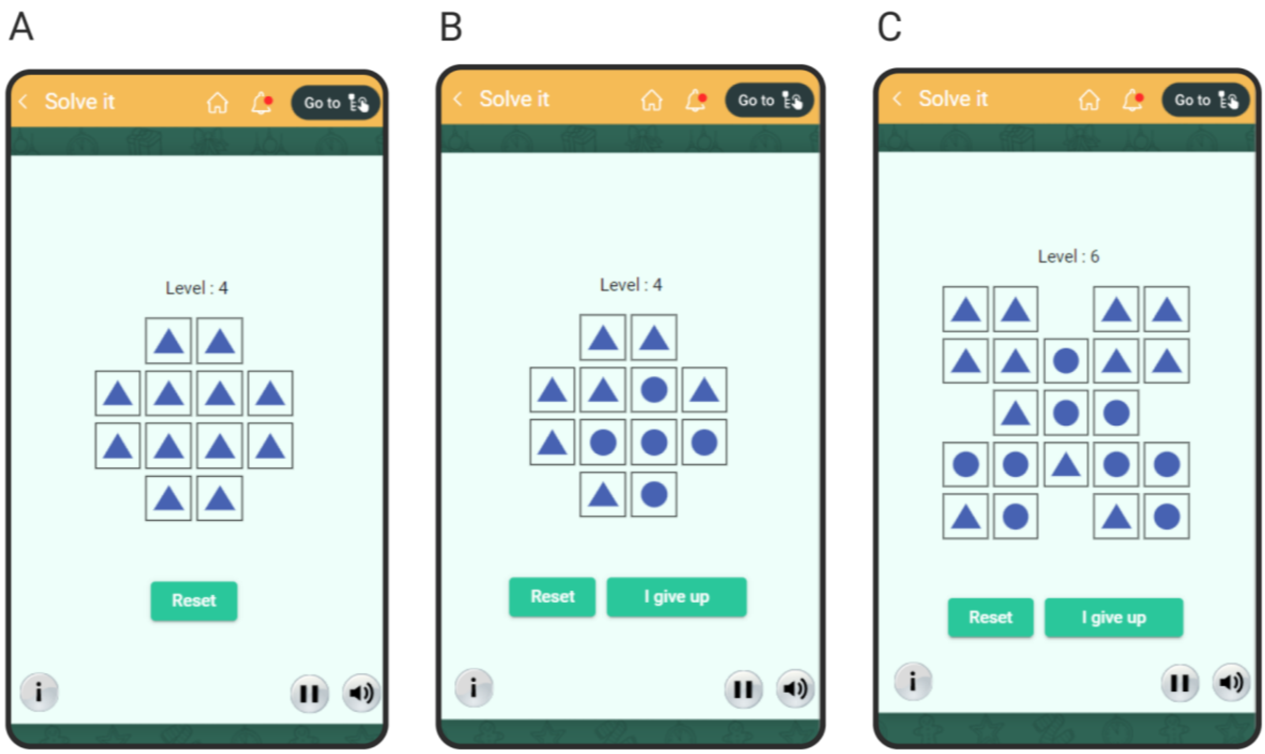


Figure 6. The 3 unsolvable mini-games within the game for learned helplessness. (A) The goal in this mini-game is to arrange the tiles in the increasing order of the numbers. Configuration A1 is solvable, and A2 is unsolvable. (B) The goal in this mini-game is to get the butterfly to sit on all the flowers. The butterfly can be moved forward and sideways using the cursor keys on a keyboard or the swipe action on a touchscreen device. Once a butterfly sits on a flower, the flower withers away and the butterfly cannot move to a position without a flower. B1 is solvable, and B2 is unsolvable. (C) The goal in this mini-game is to insert the small red arc into the big blue arc. The user can move the solid black ball using cursor keys or swipe action to the adjacent squares (if the square contains an arc open in the direction of the ball, the ball moves inside the arc). Once the ball is inside an arc, the arc can be moved along with the ball to an adjacent square that is empty or contains a bigger arc with an opening in the direction from which the smaller arc is coming. The ball comes out of the small arc if moved in the direction in which the arc is open. C1 is solvable, and C2 is unsolvable.

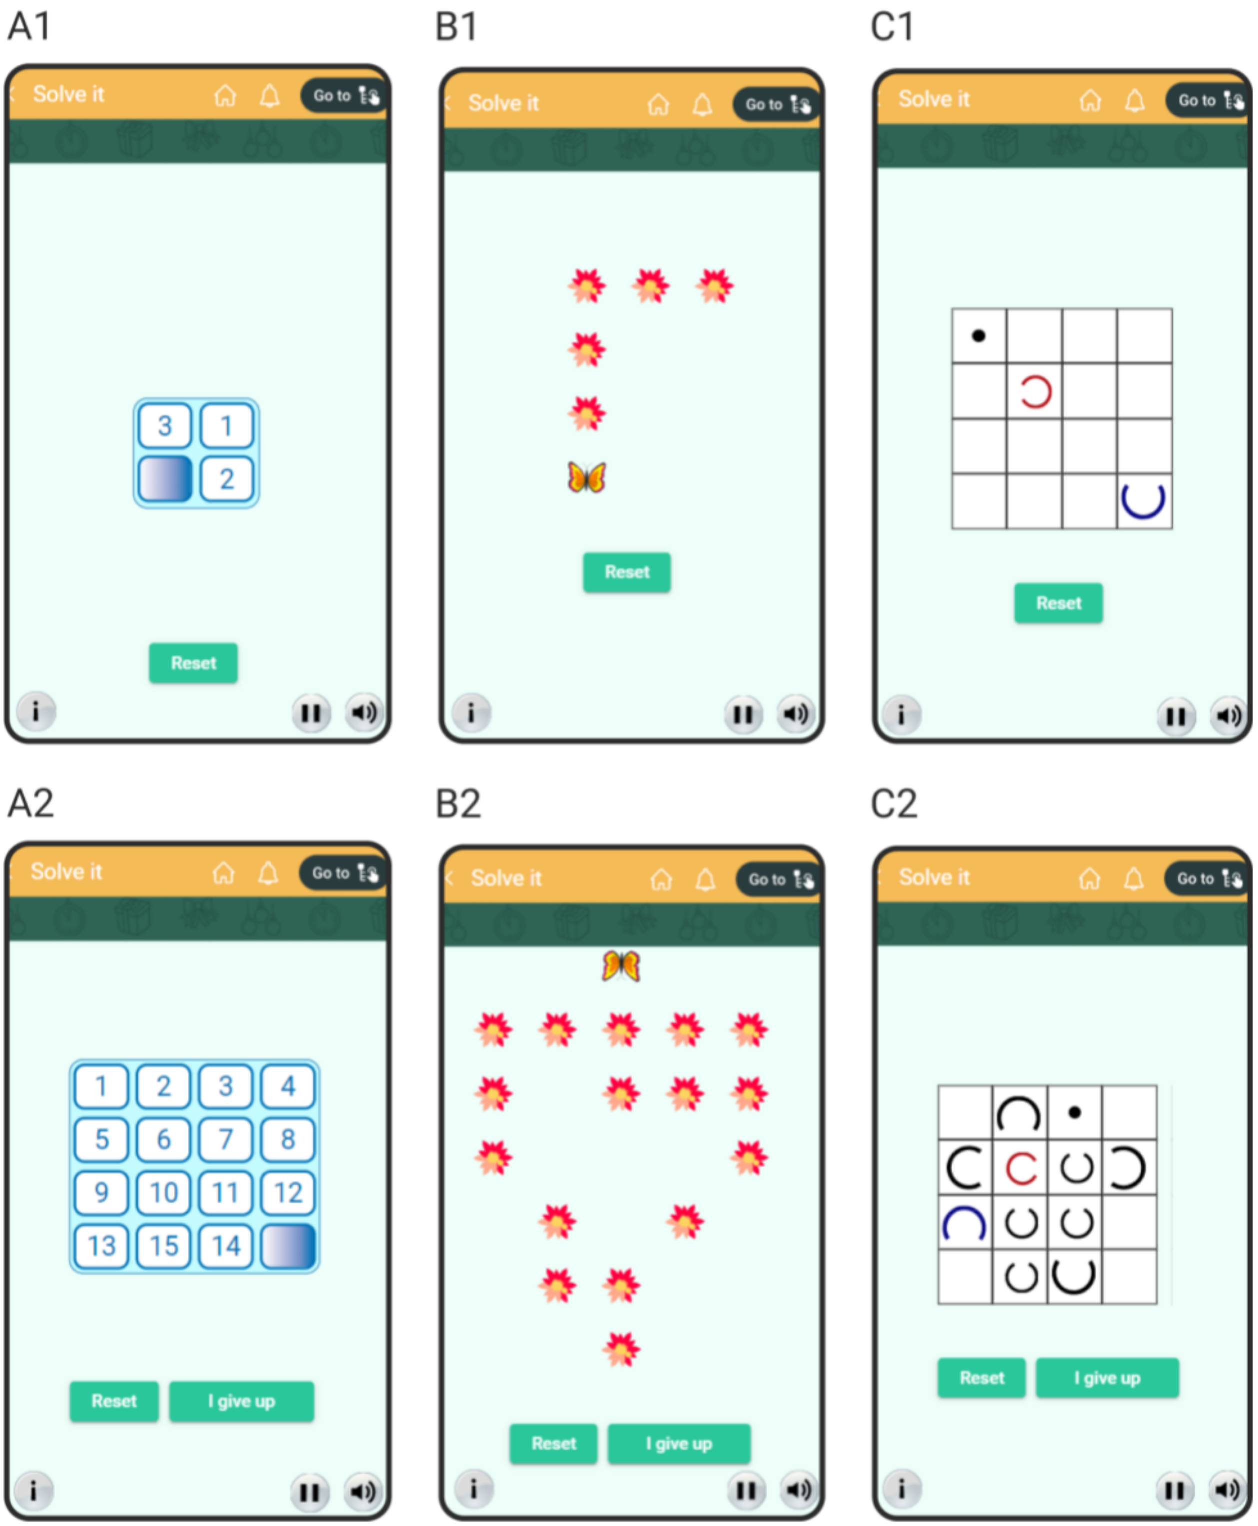

Figure 7. Flowchart describing the sequence of mini-games in the game for learned helplessness. CTML: circle-triangle mini-game level.

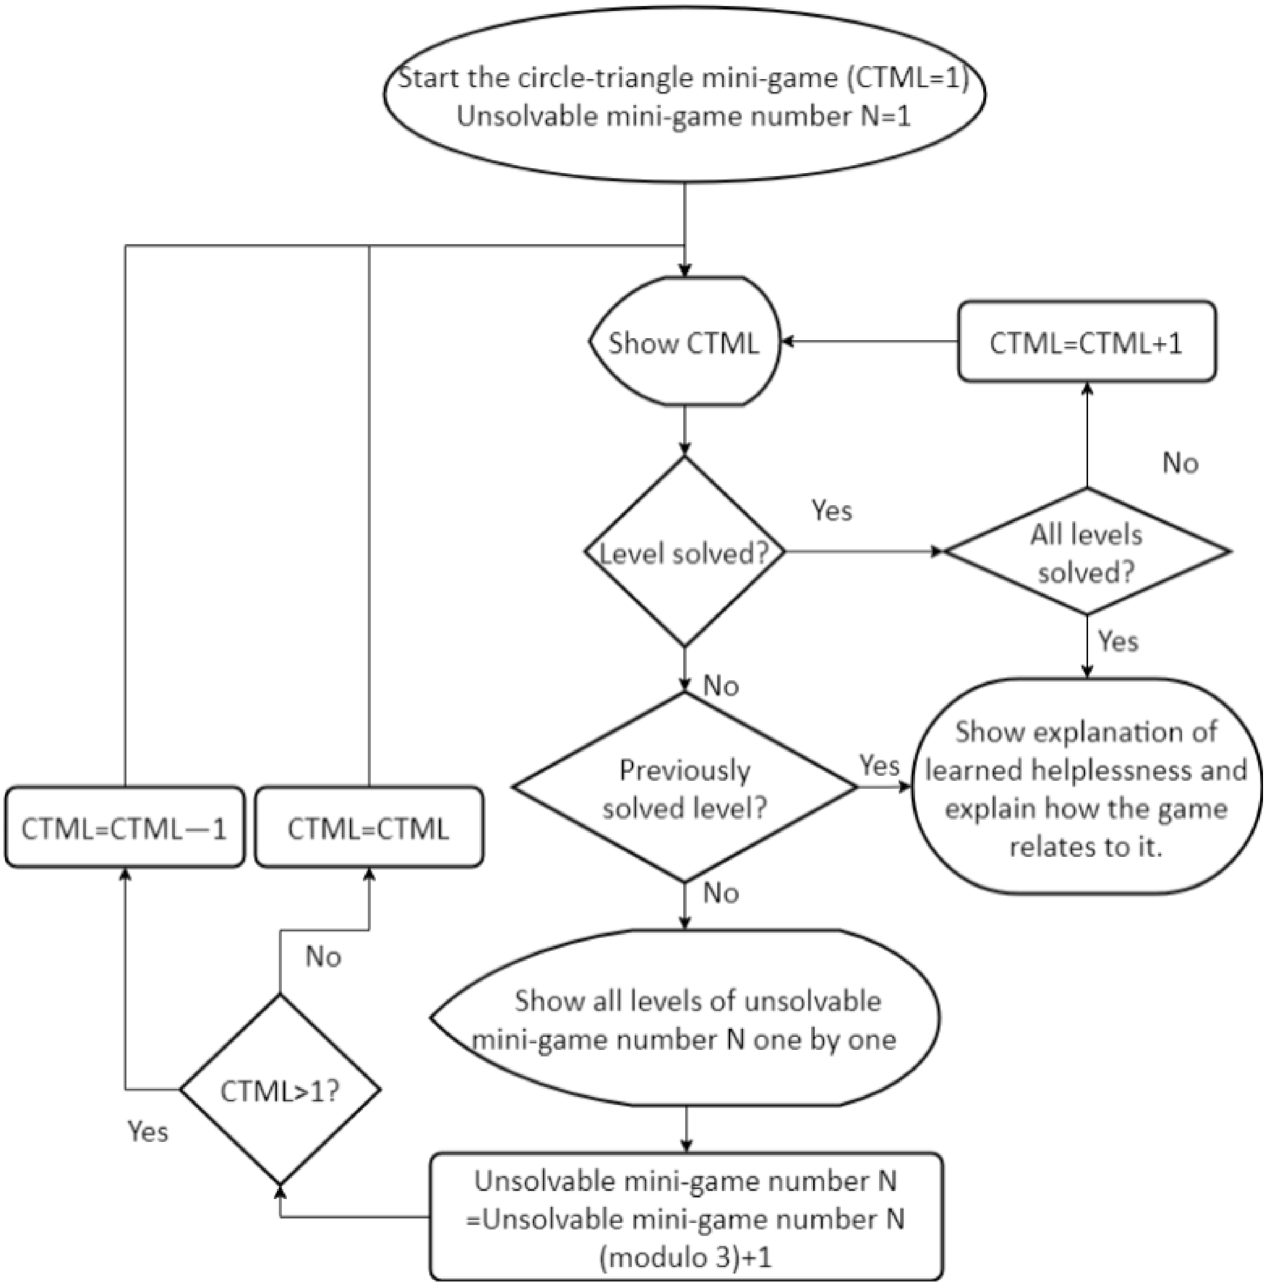

If the user does not give up on the last solved level of the circle-triangle mini-game, they reach the next level within the same mini-game, and the game continues as normal. Once they give up on a higher level of the circle-triangle mini-game, they are shown a different unsolvable mini-game. This cycle of alternating between the circle-triangle mini-game and a different unsolvable mini-game continues until the user gives up on a previously solved level of the circle-triangle mini-game or completes all levels in it (the difficulty of the higher levels ensures that the latter scenario is unlikely).

The 4 puzzle-based mini-games are designed to be engaging and challenging to play. The difficulty level in the circle-triangle mini-game adapts to the competence level of the users. The screen displays the current level to provide the user with a sense of progress. The user receives a gold badge on finishing the game. Unlike other games in TreadWill, this game was designed to be played for a limited time, until the explanation of learned helplessness and the idea of the game were shown; however, the users are free to play it again if they wish.

How Game-Like Are Our Games?

Cugelman [106] has suggested 7 core elements of gamification. Each of the games we had designed incorporated 6 of the 7 elements, including goals, challenges, feedback, rewards, progress, and fun; the only element not included in our games is social connectivity, as the games were designed to be played individually as part of a mental health intervention. Table 1 describes how the core elements are incorporated into each game.

Table 1. Core game elements incorporated in different games.

Game	Goals	Challenges	Feedback	Rewards	Progress	Fun
Automatic interpretation bias modification	Finding words in the alphabet grid to complete the sentence	Finding words from the grid within the allotted time	Points for finding words and positive interpretation	Points and badges	• In-level progress using progress bar • In-game progress using difficulty bar	Finding words in the alphabet grid
Executive control training	To keep the avatar alive as long as possible and collect coins	Avoid the obstacles at an increasingly faster speed	Points for keeping the avatar alive	Points and badges	• In-game progress via increasing avatar speed	Gameplay similar to *Super Mario Bros.*
Negative attention bias modification	To click on positive faces	To complete the song within the allotted time and avoid clicking on negative faces	Point and progress in level for clicking positive face and reduction in life for clicking on negative face	Points and badges	• In-level progress using progress bar • In-game progress using difficulty bar	The music along with the game play
Positive imagery training	To progress in the game by providing positive resolutions	Finding the right word	Points and progress in level for positive resolutions	Points and badges	• In-level progress using progress bar	Imagining the self-referent situations
Learned helplessness	Solving the puzzles	Solving the puzzles	Positive feedback for solving a puzzle	Badge	• For the solvable game, levels are shown	Solving the puzzles

Feedback on the Games

The feedback for all games obtained from the 15 pilot users (*Methods* section) is summarized in Figure 8. In most cases, there was statistically significant positive feedback on the clarity of instructions, fun in gameplay, and clarity of purpose (all $P<.05$; Table 2), showing that the games were acceptable to the users. According to the user feedback (Figure 8A-E), the games for negative attention bias modification (Figure 8C) and positive imagery training (Figure 8D) had the clearest instructions; the game for learned helplessness (Figure 8E) was the most fun to play; and the game for positive imagery training (Figure 8D) had the clearest purpose. The game for learned helplessness was able to achieve its purpose: 11 (73%) out of 15 users said that they had a better understanding of the idea of learned helplessness after playing the game. The game was able to induce anger or frustration in 6 (40%) out of 15 participants, of which 4 (67%) of the 6 mentioned that their anger or frustration reduced once the logic of the game was explained (overall, 7/15, 47% users reported a reduction in anger or frustration). Only 2 (13%) out of 15 participants reported that their anger or frustration did not reduce once the logic of the game was explained.

Figure 8. Acceptability results of the game for (A) automatic interpretation bias modification, (B) executive control training, (C) negative attention bias modification, (D) positive imagery training, and (E) learned helplessness. Overall (1) the instructions for the games were clear; (2) the games were fun to play; and (3) the purpose of the games was clear.

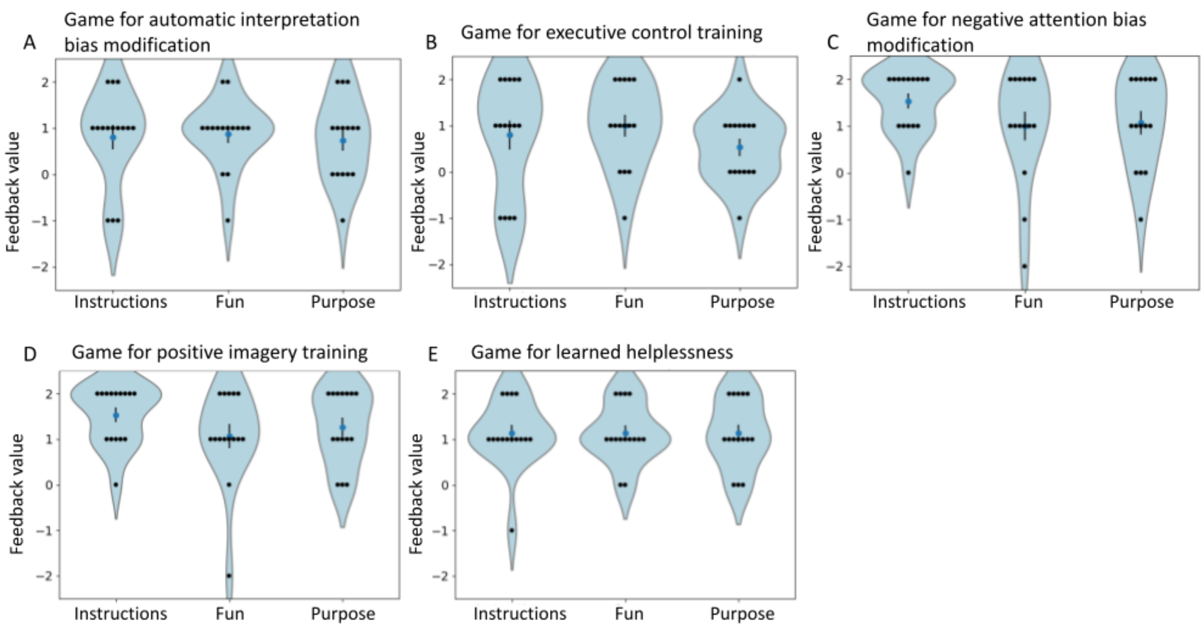

Table 2. Summary of feedback on the games from 15 pilot users. Each game was rated on 3 parameters on a 5-point Likert scale, in which 2=strongly agree, 1=agree, 0=neutral, −1=disagree, −2=strongly disagree. The *P* value corresponds to Wilcoxon signed rank test against 0.

	Values, mean (SD)	*P* value
Automatic interpretation bias modification		
Instructions	0.800 (1.014)	.02
Fun	0.867 (0.743)	.003
Purpose	0.733 (0.883)	.02
Executive control training		
Instructions	0.800 (1.207)	.03
Fun	1.000 (0.926)	.004
Purpose	0.533 (0.743)	.04
Negative attention bias modification		
Instructions	1.533 (0.639)	<.001
Fun	1.000 (1.195)	.01
Purpose	1.067 (0.961)	.003
Positive imagery training		
Instructions	1.533 (0.639)	<.001
Fun	1.067 (1.032)	.005
Purpose	1.267 (0.798)	<.001
Learned helplessness		
Instructions	1.133 (0.743)	<.001
Fun	1.133 (0.639)	<.001
Purpose	1.133 (0.743)	<.001

Discussion

Principal Findings

This paper describes the design of 4 serious games based on CBM paradigms and 1 serious game based on the learned helplessness theory. We expect that delivering the CBM paradigms in the form of serious games will increase the paradigms' engagement and consequent effectiveness. Currently, cCBT is the predominant digital intervention modality used for depression. Despite some early attempts at combining cCBT and CBM [23,32,33], no well-evaluated and widely available software intervention offers both. One likely reason is that users are not motivated to use the CBM paradigms in their raw forms. Incorporating game-based CBM paradigms in digital interventions might serve the following 2 purposes: increase engagement with the overall interventions and serve as a complementary therapeutic approach to CBT. Overall, all the games received positive feedback on all 3 aspects—whether the instructions were clear, whether the game was fun to play, and whether the purpose of the game was clear (Figure 8). In addition, the learned helplessness game was able to achieve its purpose of explaining learned helplessness via experiential learning.

Optimization of Game Paradigms

Two of the CBM paradigms described in this paper, the negative attention bias training [92] and the positive imagery training [94], were previously converted into serious games. In particular, the negative attention bias training paradigm has inspired many serious games. However, only a few have been evaluated in research studies [62,107,108], whereas the rest are commercially available without evaluation. The Bias Bluster game [109] was developed based on the positive imagery training paradigm.

We made slight modifications to 3 of the CBM paradigms to make them suitable for use in the games while keeping their active ingredients intact. In the original automatic interpretation bias modification paradigm, a sentence was shown for 1000 milliseconds [21]. However, during our internal testing, we observed that 1000 milliseconds was not appropriate for all sentences and, in general, too short for nonnative English speakers. Therefore, we showed the sentence for a duration dependent upon the length of the sentence, computed by *100 + (TC / ARS)* milliseconds, where *TC* denotes the total number of characters in the sentence and *ARS* denotes the average reading speed (estimated to be approximately 50 characters per 1000 ms).

In the original negative attention bias training paradigm, the images were presented in a 4 × 4 grid [92]. During the internal testing, we observed that a 4 × 4 grid on a smartphone screen makes the individual images very small and the emotions in the images indiscernible. Considering the higher penetration of smartphones than computers or tablets, we presented images in 2 × 1, 2 × 2, or 3 × 2 grids to ensure that the images and emotions could be seen easily.

In some of the previous implementations of the positive imagery training paradigms, the scenarios were presented in an auditory format and the positive resolutions were provided to the user by the program directly [25,94,95,97,100]. We presented the scenarios using a text-based format, similar to Mathews and Mackintosh [98], as the auditory format is less amenable to gameplay (eg, an audio clip is slower to scan back and forth compared with text). Furthermore, we designed the game such that the user was required to come up with a positive resolution to the ambiguous scenario. This modification was inspired by the observation that the training was more effective in changing the mood if the interpretation was actively generated by the user [98].

Limitations and Future Directions

Feedback from the users in this study indicates that serious games based on CBM paradigms are acceptable. However, this study had a small sample size. There is a need for more studies with larger, more diverse, and clinical samples to test the real-world engagement and effectiveness of the games. In the future, games can be made more engaging using virtual reality.

Conclusions

Serious game–based mental health interventions are acceptable to users and have the potential to increase their engagement with digital mental health interventions. The designs we have provided can also be adapted into other interventions for many other disorders in which cognitive biases are involved [110]. We expect that the inclusion of serious games based on the CBM paradigms will help in improving the effectiveness and engagement of digital interventions.

Acknowledgments

The authors thank the members of the NG laboratory for testing the initial versions of the games and providing feedback on the content and user experience. In addition, the authors thank professor Arjun Ramakrishnan and Abin Thomas for help in recruiting participants for the pilot trial. They also thank Arun Shankar and Ranjeet Kumar for labeling the images used in the game for the negative attention bias modification. Face images used in the game for negative attention bias training were collected from multiple sources: White—Psychological Image Collection at Stirling [111]; African and Asian—tarrlab [112] (courtesy of Michael J Tarr, Carnegie Mellon University; funded by National Science Foundation award 0339122); and Indian—photographed by us. This work was supported by the Cognitive Science Research Initiative (CSRI) of the Department of Science and Technology (DST; grant DST/CSRI/2018/102). The NG laboratory is supported by the DST Science and Engineering Research Board Swarnajayanti Fellowship (grant SB/SJF/2021-22/04-C). The funding agencies had no role in the design or implementation of the study and in the interpretation of the results.

Data Availability

The deidentified data analyzed in the pilot study are available from the corresponding author upon reasonable request.

Authors' Contributions

AG and NG conceptualized the project. AG searched the literature for cognitive bias modification paradigms and suggested the initial game ideas that were refined and finalized after discussion with NG and other authors. AG, JA, SB, BKS, LA, AA, ST, KM, SR, YA, and SG developed the games. AG and NG wrote the paper with inputs from all coauthors.

Conflicts of Interest

None declared.

Abstract

Background: There is serious concern over the annual increase in depressive symptoms among millennials in Bangkok, Thailand. Their daily routine revolves around the use of their smartphones for work and leisure. Although accessibility to mental health care is expanding, it cannot keep up with the demand for mental health treatment. Outside Thailand, multiple projects and studies have attempted to merge gamification mechanisms and cognitive behavioral therapy (CBT) to create mobile health intervention apps and serious games with positive feedback. This presents an opportunity to explore the same approach in Thailand.

Objective: This study investigated the development process of gamifying CBT techniques to support game mechanics in a visual narrative serious game, BlueLine. The primary target of this research is Bangkok's millennials. In the game, players play as Blue, a Bangkok millennial who struggles to live through societal norms that influence his digital life and relationships. Through in-game scenarios, players will learn and understand how to lessen the impact of depressive symptoms via gamified interactions on their smartphones.

Methods: First, this paper follows each development step of solidifying BlueLine's game structure by integrating the Activating Events, Beliefs, Consequences, Disputation of Beliefs and Effective New Approaches (ABCDE) model and narrative in games. Second, the approach to select CBT and related therapeutic elements for gamification is based on suitability to the game structure. Throughout the process, CBT experts in Thailand have reviewed these scenarios. The approach forms the base of the player's interactions throughout the scenarios in BlueLine, broken down into 4 types of gamified mechanisms: narrative, verbal interactions, physical interactions, and social media interactions.

Results: With the game structure based on the ABCDE model, BlueLine scenarios implement gamified mechanisms in conjunction with the following CBT and related therapeutic elements: behavioral activation, self-monitoring, interpersonal skills, positive psychology, relaxation and mindful activities, and problem-solving. In each scenario, players guide Blue to overcome his triggered dysfunctional beliefs. During this process, players can learn and understand how to lessen the impact of depressive symptoms through gamified interactions.

Conclusions: This paper presents the development process of gamifying CBT and related therapeutic techniques in BlueLine game scenarios. A scenario can harbor multiple techniques, including behavioral activation, self-monitoring, interpersonal skills, positive psychology, relaxation and mindful activities, and problem-solving. BlueLine's game structure does not limit the fact that the same combination of CBT elements ties each gamified mechanism.

Introduction

Background

Nowadays, most millennials in Bangkok, Thailand, have adopted a long-hours working culture, which allows little time to relax and unwind. Social media has become the platform of choice, whether it is used to socialize with others or to catch up on public health warnings, such as those issued during the COVID-19 pandemic [1]. From 2016 to 2020, the number of social media users in Thailand jumped from 32 million to 52 million, approximately 80% of the population, with an average of 2 hours and 55 minutes of web-based social exposure per day [2]. After a long period of social media use, a possible side effect is social comparison, such as seeking acceptance and confidence from external sources [3]. Thus, it plays an essential role in influencing one to develop depressive symptoms [4].

A total of 20,685 Bangkok millennials responded to Thailand's Department of Mental Health survey in 2021 [5]. The risk of developing depressive symptoms in this group is frighteningly high at 48.97%, and, compared with provinces outside the capital, it is 4 times higher [6]. The survey was completed using the Patient Health Questionnaire (2-question version, 8-question version, and 9-question version) mental health survey system that is based on the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5).

Since the outbreak of COVID-19, depressive symptoms have become more apparent among Bangkok's millennials [5-7]. During the pandemic, there were constant actions to promote mental health care awareness by hospitals and schools to provide quality and sustainable mental health care services [8]. Nonetheless, exposure to help is still limited, as was the case especially during the COVID-19–related lockdown period [9,10]. More services must therefore explore other approaches to reach patients experiencing depressive symptoms.

Smartphones are becoming a unanimous part of our daily routine, creating a window of opportunity to increase access to mental health care [11]. This can be in the form of serious games (designed for purposes beyond entertainment), which are part of applied games; games based on cognitive behavioral therapy (CBT) constitute 1 of the 6 major categories of tested games for mental health [12]. This approach can benefit players with favorable emotional treatment through awareness, behavior changes, and relief of symptoms [13,14]. Mobile mental health intervention is affordable and can be used adjunctively with the patient's existing treatment [15].

Integrating CBT Techniques Into Games

In recent years, studies have attempted to develop frameworks to create practical approaches to developing gamified apps. However, most still need to be fully established [16,17]. It is challenging to integrate CBT into different contexts of each game while ensuring that it achieves the intended experience and treatment goal for the players [18]. In this paper, the term *intended experience* refers to the expected gameplay experience of the player (ie, the quality of the gameplay interactions) [19]. It is plausible to integrate CBT techniques into games as multiple successful projects existing in different regions have shown (eg, a mobile health [mHealth] app for Māori [Indigenous New Zealand people] youth with emotional difficulties, Quest Te Whitianga) [20]. Night in the Woods (a winner of the British Academy of Film and Television Arts games award for narrative) is the story of Mae, who is dealing with depression and anxiety as she quietly returns to her hometown [21].

This paper breaks down the development process of a gamified intervention incorporating CBT techniques into BlueLine. The overall intended experience for BlueLine is for the player to live through scenarios as the main character where they are given choices and can perform actions that incorporate the following therapeutic components: behavioral activation, self-monitoring, interpersonal skills, positive psychology, relaxation and mindful activities, and problem-solving.

Methods

Overview

BlueLine is a visual narrative serious game where the player plays as Blue, a Bangkok millennial who struggles to live through societal norms that influence his virtual life and relationships. The game is inspired by Florence [22], in terms of the way the narrative expresses through visuals, and by We Should Talk [23], in terms of how the player's verbal choices affect their emotional state and lead to certain consequences in the game's world. This game primarily targets mobile platforms, and most Bangkok millennials use them, especially those who exhibit depressive symptoms. The game is also designed to be approachable to casual players. On release, BlueLine will be playable in both Thai and English to support the primary target group.

In the early stages of developing BlueLine, the focus was to create prototypes that could successfully integrate the gamification of CBT techniques into narrative design and harmoniously use visual design as the core gameplay. Our design process includes medical doctors and therapists who frequently care for Bangkok's millennials. It allows us to circumvent the limited studies on the use of CBT in Thai games available at the time of this research. We will conduct a randomized controlled trial of the complete BlueLine prototype to assess its efficacy, acceptability, and usability with the support of Thailand's Department of Mental Health.

First, we must understand the behavior of our primary target audience, the millennials of Bangkok. The behavior patterns of popular activities among this group establish statistics, especially the popular interactions in each social media application [24,25]. It also includes the time spent on each web-based activity. From a game design point of view, creating scenarios by researching and understanding the habits of the target audience can lead to better engagement and enable delivering of the intended experience [26]. Our design team has created these scenarios to be approachable even to people who do not have depressive symptoms. Through these CBT-gamified interactions, players can absorb information to become familiar with how to cope with depressive symptoms. They can fail safely without social consequences in real life. Each game scenario will also have its intended experience, aligning with its intended experience.

Second, we aimed to obtain insight from experts who have experience using CBT techniques to treat Bangkok's millennials. For a better understanding of the game design of this project, we created short scenarios in the form of storyboards and gameplay mock-ups in the form of animation to help the experts to express their opinion on how the game will affect their patients and to suggest details that can improve the effectiveness of the CBT-infused interactions. These short scenarios are experimental prototypes that explore how we can merge CBT techniques and gamification elements. Successful prototypes that deliver the intended gameplay experience will be compiled into the game later.

The feedback from monthly meetings with the experts is critical in developing future iterations. Playtests were held within the team frequently, followed by group discussions, which were also immensely invaluable for our developers with CBT-related experience. They shared opinions on aspects that they feel are beneficial and need improvement. This technique of verbalizing thought processes in usability testing is called *thinking aloud* [27]. At this stage, the emphasis was on ensuring that the prototype was complying with the intended experience while incorporating placeholder art assets. This was a standard game development process to prove that the participative elements in the gameplay can be practical without having to rely heavily on aesthetics.

Selecting CBT Techniques as the Game Structure

CBT is an evidence-based treatment for psychiatric disorders, including depressive symptoms. This treatment involves attempts to change ways of thinking and behavior patterns through understanding negative thoughts, emotions, behaviors, and physiological reactions, thereby relieving their symptoms [28]. This helps individuals learn to be their own therapists [29].

For BlueLine, the game's core structure implements the Activating Events, Beliefs, Consequences, Disputation of Beliefs and Effective New Approaches (ABCDE) model. It is a simple mnemonic developed in the field of rational-emotive behavior therapy by Albert Ellis [30]. This model targets beliefs as a fundamental course of treatment. It guides the individual to break down the event and carefully examine the causes and effects so that they may respond to the situation in an improved manner if it recurs [31].

The core structure often integrates the ABCDE model in several CBT-based applications and serious games. One such application is Self-help, Integrated, and Gamified Mobile Phone Application, a gamified mHealth intervention, and it is used as an evidence-based theoretical structure for players to overcome their maladaptive beliefs [32], whereas REThink is a clinically tested therapeutic game for college students to manage distress efficiently [33], and ReWIND is a role-playing game that allows players to overcome their generalized anxiety disorder through anxiety-causing encounters [34]. Similar to BlueLine, they all use the ABCDE model to challenge dysfunctional beliefs in a safe virtual environment for their audience. Following this model, BlueLine's structure is divided into 5 steps (Textbox 1).

These 5 steps can match well with the narrative in a visual narrative game structure, as shown in Textbox 2. We can resolve the narrative tension by disputing beliefs and practicing new approaches. In addition, this allows other CBT and related therapeutic techniques to work in conjunction and still perform efficiently, including behavioral activation [35], self-monitoring [36], interpersonal skills [37], positive psychology [38], relaxation and mindful activities [39], and problem-solving [40].

Textbox 1. The Activating Events, Beliefs, Consequences, Disputation of Beliefs and Effective New Approaches (ABCDE) model as a game structure from a player's point of view.

A: activating event

- Players identify their main character's trigger during a distressing scenario in the game.

B: beliefs

- Players understand the underlying dysfunctional belief as the scenario plays out by observing how the main character reacts.

C: consequences

- The impacts of the main character's beliefs influence physically within the game's world (character actions and surroundings) and psychologically (emotions).

D: disputation of beliefs

- The main character will attempt to challenge their dysfunctional beliefs through a series of player interactions in the game.

E: effective new approach

- The main character manages to transform their initial dysfunctional beliefs. The player will witness positive changes in the main character's mindset.

Textbox 2. A narrative scenario in the Activating Events, Beliefs, Consequences, Disputation of Beliefs and Effective New Approaches (ABCDE) model.

Activating event

- Blue is forced to stay late at the office. Even after he gets home, he gets another call from work and has to stay up to work.

Beliefs

- He feels worthless. No matter how hard he works, the office is not happy.

Consequences

- He feels unappreciated, drained owing to lack of sleep, and loses interest in activities.

Disputation of beliefs

- He recognizes that the office is taking advantage of him and that he should not devalue his worth based on other people's words.

Effective new approach

- He discusses with the management his plan to not work after business hours and starts to perform recreational activities instead.

BlueLine simulates scenarios in safe virtual environments; players have the comfort of time to identify dysfunctional beliefs before they can happen. This way, they can see the consequences of their choices through self-monitoring the game character. The game allows players to challenge dysfunctional beliefs through its main character, Blue.

Following this structure, we aimed to scale up BlueLine because we plan the gameplay length to be approximately 1 hour and 20 minutes. We aimed to manage players' time on a single playthrough of BlueLine, thus lowering the risk of preoccupation with the game, which is one of the symptoms of internet gaming disorder in DSM-5, Text Revision [41]. Several factors are related to addictions, such as life satisfaction [42] and the types of games (on the web and offline) [43]. Statistically speaking, players who spend long weekly gaming hours (approximately 20 hours per week) are more likely to develop depressive and addiction symptoms [44].

BlueLine gameplay has 15 chapters, each lasting 5 minutes on average. The game will offer pause and resume features. Players do not have to finish a chapter in 1 session and have the option to resume from where they left off. Our players may not return to the game because a lack of motivation can be related to depressive symptoms [45]. This presents an opportunity for a reminder feature to encourage players to resume the game through timely notifications; for example, the game would deliver notifications during the evening but not late at night. This reminder feature also exists in internet-based CBT applications [46] and eHealth programs [47].

Storyboards are also developed during this process, with mock-ups created to test the composition of visual elements on a smartphone screen. While sketching the storyboards, many discussions arose about specific moments, leading to more inspiration to develop the narrative further. We can determine which CBT-infused action the main character could perform by seeing the sketched character in the scenario. We specifically designed the color palette and animation to ensure that players are not exposed to specific light patterns or flashing lights, which can lead to photosensitivity epilepsy or blackouts. Thus, storyboards guide the next step—the gamification of CBT techniques.

Approach to Gamification of CBT

The challenge is to gamify CBT techniques appropriately and fit them into each scenario. The chosen approach is based on case-by-case scenarios, with the end goal being that the interactions should be meaningful to the player. Meaningful play occurs when the player's action has immediate importance and affects the larger context of the game [48]. We were able to accomplish this by basing the content of BlueLine on Bangkok's millennials, including their daily routines, behaviors, and life experiences. This shapes the identity of Blue (the main character), who would face and overcome obstacles in the story.

Gamification Elements

We divide BlueLine's CBT gamification elements into 4 main components: narrative, verbal interactions, physical interactions, and social media interactions. We acknowledge that existing studies discuss gamification elements in CBT-based applications, such as scores, levels, and tokenized rewards [49,50]. However, there are difficulties implementing them in BlueLine because it is not in the nature of a visual narrative game to have repetitive elements. Table 1 shows the core structure of gamification mechanisms, and other use cases will be discussed in the *Results* section.

Table 1. Gamified mechanisms in BlueLine.

Gamification of CBT[a] in mechanics and description	Use in BlueLine
Narrative	
Growth of Blue as a representation of Bangkok's millennials	• The story is told from the perspective of Blue and his millennial daily routine, lifestyle, and life choices. Through the ups and downs in the story, Blue struggles with the triggering of his dysfunctional beliefs and overcoming them. • CBT techniques: self-monitoring, problem-solving, and interpersonal skills
Verbal interactions	
Engagement in conversation	• Blue participates in conversations with NPCs[b] throughout the game. Each NPC's reply contains therapeutic components depending on the player's verbal choices. • CBT techniques: self-monitoring, interpersonal skills, and behavioral activation
Physical interactions	
Activities that require Blue's physical action	• Blue participates in multiple activities that require him to perform the task physically. Interactions range from basic actions such as walking to complicated tasks such as grocery shopping and giving a love letter. • CBT techniques: relaxation and mindful activities and problem-solving
Social media interactions	
Scrolling through social media and likes	• This feature mimics a social app where players can scroll through the social feed in the game's world. The content in the feed is generated by design to match the intended experience of that scenario. It is not linked to any actual social apps. Generated posts are visual based to avoid negative trigger words. • CBT technique: self-monitoring
Photo mode	• This feature is a version of the camera app on mobile phones. The scenes that players see through the lens are generated by design, inspired by actual real-life locations. • CBT techniques: relaxation and mindful activities

[a]CBT: cognitive behavioral therapy.

[b]NPC: nonplayer character.

Results

Overview

This section details several scenarios where each gamification mechanism is integrated with CBT and therapeutic techniques. There is a degree of flexibility in which specific scenarios can have multiple gamification mechanisms and therapeutic techniques, whereas the core structure includes the ABCDE model.

Narrative

Depressive symptoms can recur, and that is the takeaway from BlueLine, which shows through player interactions that CBT and therapeutic techniques can reduce the risk of relapse as long as it is maintained [51]. BlueLine will take players through multiple scenarios built under the expanded ABCDE structure (Tables 2 and 3). This version adds a chapter column to support the upscaled story. A DSM-5 column is added to assess Blue's depressive symptoms at each stage of the story. This serves 2 purposes. First, it keeps the developers and consulting experts informed about exposure to depressive symptoms during the design and production stages. Second, it identifies moments in BlueLine where the game could encourage players to be open to seeking mental health care. This approach could circumvent the unwillingness of Asian communities to access help from mainstream services [52]. Throughout the game, visual keys are placed to subtly help the player gain confidence to reach out for help if needed; for example, a customized billboard of a real-life mental health care service will be placed far in the background but still legibly visible.

Table 2. BlueLine's Activating Events, Beliefs, Consequences, Disputation of Beliefs and Effective New Approaches (ABCDE) structure with a narrative framework and a Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) column.

BlueLine: Chapter 9, scenario 3	DSM-5 A1[a]-A9	ABCDE model
Blue and his partner have a minor quarrel over the photos he has taken.	__[b]	Activating event: Blue tries to apologize because the photos he took were not his best.
Line thinks that Blue is not trying hard enough and believes that he does not care.	—	Beliefs: Blue feels he has messed up. In the hope of being forgiven by Line, he keeps apologizing to her.
Line vents at Blue.	—	Consequences: Blue feels insignificant and worthless because she despises the photos he took.
The player stops Blue from panicking.	—	Disputations of belief: Blue stops apologizing (stays silent) so that Line can gather her thoughts.
Line realizes that Blue did try his best.	—	Effective new approach: Blue learns that by not panicking, he enables Line to understand his worth.

[a]A1 to A9: assessment of depressive symptoms at each stage of the story.

[b]To be filled in by the developers and consulting experts.

Table 3. An ABCDE[a] model breakdown of the conversation exchanged between Blue and Line in chapter 9 of BlueLine.

	Activating event	Beliefs	Consequences	Disputation of beliefs	Effective new approach
Narrative	• Blue and Line are having breakfast after the sunrise photo shoot. The couple begins to quarrel.	• Line thinks that Blue is not trying hard enough and believes that he does not care.	• Line vents at Blue.	Blue cannot continue to apologize because the game prevents the player from saying "Sorry" by fading out the "Sorry" button.	Line realizes that Blue does try his best and that the way she expresses herself has a negative effect on Blue.
Blue	• Blue tries to apologize because the photos he took were not his best. • Player begins self-monitoring.	• Blue feels he has messed up. In the hope of being forgiven, he keeps apologizing (achieved by the player pressing the "Sorry" button). • DSM-5[b] symptoms: • A7[c]: a sense of worthlessness • A8: impaired concentration	• Blue feels insignificant and worthless because she despises the photos. • DSM-5 symptoms: • A1: depressed mood • A2: lack of interest • A6: fatigue • A7: a sense of worthlessness • A8: impaired concentration	Interpersonal skills (using silence): Blue uses silence so that Line can gather her thoughts.	Behavioral activation: Blue learns that sometimes a moment of silence can help others to regain their minds.
Line	• Line is angry because the photos taken by Blue are not good enough.	• She thinks that the photos are bad because Blue does not care. She does not want to listen to any excuses or apologies.	• Line feels unappreciated and blames Blue. • DSM-5 symptoms • A2: lack of interest • A8: impaired concentration	Interpersonal skills (giving recognition): Line realizes that her words have hurt Blue.	Behavioral activation: Line learns to appreciate and give recognition when others are trying their best.

[b]DSM-5: Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.

[c]A7 and so on: assessment of depressive symptoms at each stage of the story.

Act 1: Refresh

It is a new beginning for Blue, who has just returned to Thailand to start a new chapter in his life with a good office job and to be with family. The player will begin appreciating the sense of well-being radiated by a motivated office worker through self-monitoring Blue's daily routine. Blue will encourage the player to complete relaxation and mindful activities throughout the day by rewarding them with positive outcomes. This is achieved by engaging in physical interactions that some might consider mundane tasks (eg, waking up at 5 AM to leave for work early to avoid the traffic). At the same time, Blue will show appreciation for a beautiful sunrise. Eventually, the same routine begins to gray out as his surroundings slowly pressure him, such as being asked to work overtime. This will subtly trigger the activating event of the ABCDE model. The player's interactions at this stage consist of following Blue's attempts to find his way back to the well-being he once experienced.

Act 2: Reaching Out

After unsuccessful attempts at socializing, Blue meets Line, a girl who is an office worker just like him. They start to bond and become more and more close after each meeting via verbal interactions. Line's characteristics serve multiple vital purposes in the game. She serves as a source for Blue's development; at times, her actions and speech are similar to those of a therapist (to help reduce the anxiety the player might feel regarding their first therapeutic appointment). When Blue is feeling low, she helps him by performing therapeutic-infused actions (eg, using interpersonal skills). She also encourages Blue to participate in relaxation and mindful activities to reduce his negative emotions via positive psychology [38] (eg, visiting gardens and mountains). After some time, she will trigger a dysfunctional belief stemming from upward social comparison. This will allow Blue and the player to reciprocate her kindness and problem-solving proficiency using the therapeutic techniques they learn during the game.

Act 3: Reconnect

This act is set during the time frame of the 2020 COVID-19 pandemic in Thailand. Although the world changes, we want to present ways to handle mental health for our stakeholders. In the story, Blue's parents ask him to return home during quarantine. He is hesitant to leave Line's side because he only recently moved in with her, but she is supportive of his decision to go back home to take care of his parents. Slowly, however, distance begins to chip away at their bond. Depressive symptoms arise from activating events through social comparison in topics such as "It is safe to go on trips because there is no close contact if nobody goes on a trip," even as the lockdown intensifies in Thailand. Ultimately, the two work together to dispute their different dysfunctional beliefs to save their relationship. The last problem-solving session involves using the related CBT techniques throughout the game to unfold the final problem. The game rewards the player with a fulfilling climax—narrative, gameplay, visuals, and sound at their peak—making the final interaction memorable for players so that they may recall the way they used behavioral activation to handle the situation were it to happen in real life.

Verbal Interactions

Interactions with other nonplayer characters (NPCs) are essential in this game. Through their voices and actions, the NPCs aim to provide therapeutic components and gamification strategies, such as reinforcement of successful behavior, and provide feedback on the player's performance through prompts [53]. Players can make verbal decisions through the dialogue-crafting system (Figure 1).

The dialogue-crafting system is inspired by the sentence-spinner mechanic from the game *We Should Talk*. The game's use of sentence crafting creates different reactions. It focuses on using a designated combination of verbal choices for players to string together. In BlueLine, we have set up 2 types of sentence crafters: the single-choice sentence crafter allows the player to change 1 part of the sentence, whereas the dual-choice sentence crafter allows 2 parts to be changed.

CBT components will be integrated based on the verbal combination put together by the player and the feedback provided through the NPC, Line (Blue's partner); for example, as shown in Figure 2, this conversation aims to surround the player with a therapeutic interpersonal relationship to make them feel cared for in a supportive, nonjudgmental environment [54].

The gameplay screen shows Blue (the player) and Line (the NPC) at a cafe. Their conversation is shown in the bubbles positioned above their heads. At the bottom is the sentence crafter. The phrase "It does get crazy" is prefixed, as shown by the solid line, whereas the switchable portion is designated by a dotted line. Although the 2 choices are worded differently, they have the same underlying intention, which is to create positive emotions through evoking a sense of well-being [38]; for example, a player whose childhood was filled with joyous and noisy moments will be able to relate more to these good memories than players whose childhood was not as joyous and noisy. This follows the concept of piggybacking in game design, using what players already know instead of teaching them from scratch [55].

The example presented in Table 3 involves depressive symptoms experienced by both Blue and Line. Together, they review the photos Blue took. Line does not like the photos; hence, Blue tries to apologize to her in an attempt to calm her down. A "Sorry" chat bubble will appear when the player presses the "Sorry" button at the bottom of the screen. However, no matter how often the player presses the "Sorry" button, Line does not calm down. To resolve this issue, the player has to stop pressing the "Sorry" button. This would prevent Blue from apologizing and enable Line to gather her thoughts. Ultimately, Line realizes that her words hurt Blue; she appreciates this and says, "Sorry. Thank you for trying your best." Throughout this scenario, self-monitoring, interpersonal skills, and behavioral activation are used.

Figure 1. Dialogue-crafting system: single-choice sentence crafter.

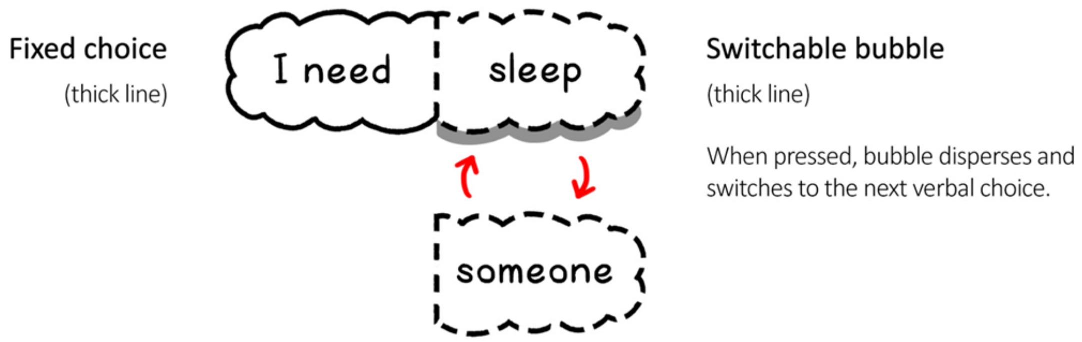

Figure 2. Breakdown of BlueLine's single-choice sentence spinner.

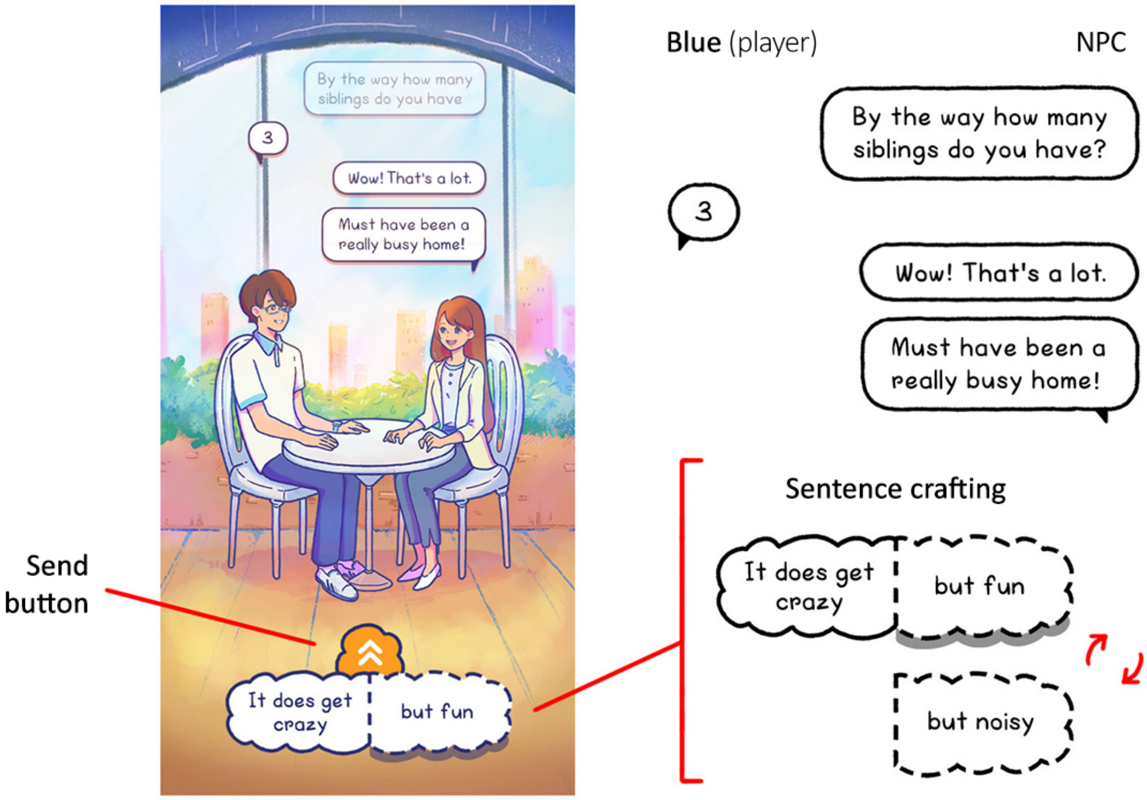


Physical Interactions

In BlueLine, physical activities expose players to therapeutic components through actions. This chapter presents 2 examples: one concerns implementing art therapy as relaxation and mindful activities, and the other concerns problem-solving.

The first scenario occurs when Blue stops by to purchase a bouquet of flowers on Valentine's Day. Instead of buying a premade bouquet, he makes one by hand (Figure 3). The goal is to teach the player that socializing is not the only means of engaging in relaxation and mindful activities. The process of art creation in art therapy also includes therapeutic elements such as self-exploration, which promotes an individual's self-awareness in terms of seeing a more positive self-image [56]. Art creation is not tied to a single medium and can vary depending on the culture concerned; some examples are painting, music, and knitting [57,58].

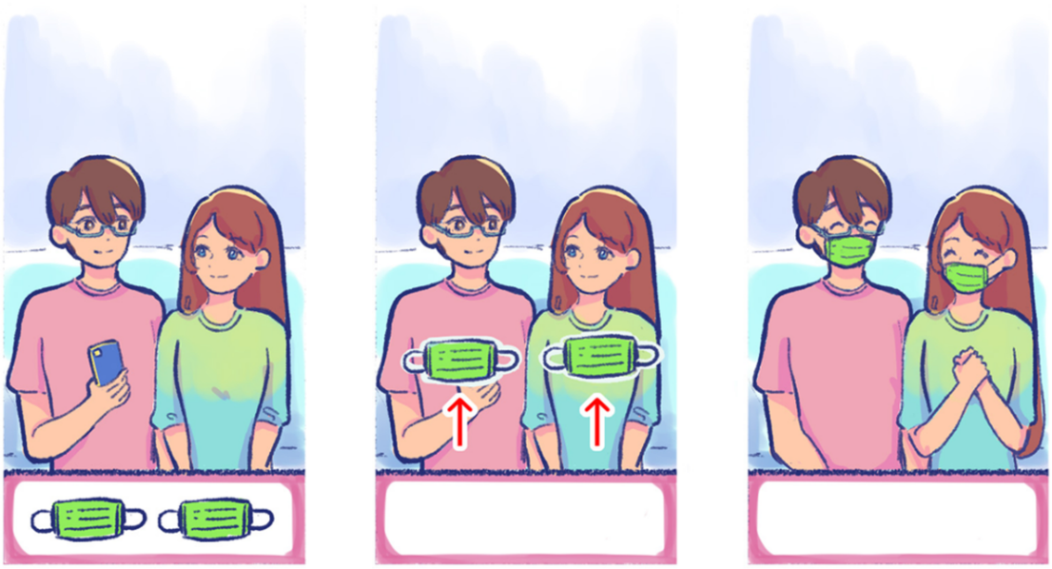
To make the experience feel tangible, the player can decorate the bouquet using their fingers to drag and drop each flower. There is a minimum placement limit before the game can proceed to the next scenario, but the player can take their time until they want to move on. We consider not tying in reward-centric game elements, such as keeping score or points for tokenized rewards, and instead allowing the journey of the interactions itself to be the reward. From our experience, this helps player engagement to last longer.

There is a moment in act 3 when Blue goes to a supermarket during the 2020 COVID-19–related lockdown in Thailand. He picks up face masks, alcohol, tissue rolls, and other necessities, but only so many items are available on the shelves.

The scenario at this stage of the game displays the risk of developing depressive symptoms during the COVID-19 pandemic in Thailand. As the population experiences more exposure to the disease and tunes in to information about COVID-19 on social media for at least 3 hours per day, there are more substantial effects on mental health in the form of anxiety and insomnia [7]. However, the process of problem-solving can be positively oriented. The solvable problem is set up for the player as a challenge and encourages their ability to resolve it effectively [40]. In Figure 4, the player will perform a swipe-up gesture with their finger to get both Blue (the player's character) and Line (the NPC) to wear masks. The players can see the progress through visually animated feedback from the 2 characters.

Figure 3. BlueLine's handmade flower bouquet: (A) before gameplay and (B) after gameplay.

Figure 4. Wearing face masks during the COVID-19 pandemic.



Social Media Interactions

According to the 2020 user behavior survey conducted by the Electronic Transactions Development Agency [59], Thai individuals spend 11 hours and 25 minutes on the internet daily, which is triple the amount compared with 2013. Instead of avoiding this topic, BlueLine uses it to visually compare a web-based lifestyle with a balanced one. Another objective is raising awareness of the players so that they can better understand the current lifestyles of Bangkok's millennials. Social media interactions are represented as social media apps and a photo mode.

The social media app in BlueLine focuses on the social feed aspect; it mimics existing social media apps, such as the Facebook, Instagram, and Twitter apps. However, the content of the feed is generated by our design team; none of it is taken from actual sources. To date, numerous studies point toward the impact of social comparison on social media on personal well-being and depressive symptoms [3,60,61]. Regarding this aspect, BlueLine intends to show players through self-monitoring that Blue's well-being improves after his fixation on social media reduces. This can be achieved through design-generated content (images, comments, and the number of likes) and controlling the time spent on social feed gameplay. Some posts do deal with social comparison to avoid players developing adverse mental health outcomes, such as a decline in psychological well-being [62], and making unfavorable social comparisons [63]; for example, a person may experience a lowering of self-esteem after they see someone showing off their material possessions in a post. In terms of duration, each social media gameplay session has been designed to last <1 minute to prevent players from engaging in heavy social media use and its associated adverse effects, such as self-harm behaviors [64] and a lowering of self-esteem [65].

As many social posts are accompanied by images, the interactive actions in the photo mode will be familiar ground for our target group. Players can use Blue's phone to take photos of various things, such as food in restaurants and natural scenery (eg, mountains; Figure 5). All the locations presented in BlueLine's photo mode are replicated from actual destinations in Thailand. This mode can catalyze players to venture outside and engage in relaxation and mindful activities (eg, visiting parks rather than shopping malls).

The player's photos will be saved into a digital photo album that acts as a gratitude journal so that players can look back at such moments and share the photos on the internet. In this album, there will be positive prewritten notations made by Blue to help remind players of the events that occurred in these scenarios (Figure 6). Gratitude reinforcement can improve daily mood and lessen adverse effects (eg, depressive symptoms) [66]. However, multiple studies suggest that combined social comparison and materialism can negatively affect subjective well-being [67-69]. Maintaining a high level of gratefulness can lessen materialistic behaviors [70]. To increase accessibility to Blue's gratitude journal, we have made it possible for players to access the album via 2 routes: the pause screen and the main menu.

Figure 5. BlueLine's photo mode.

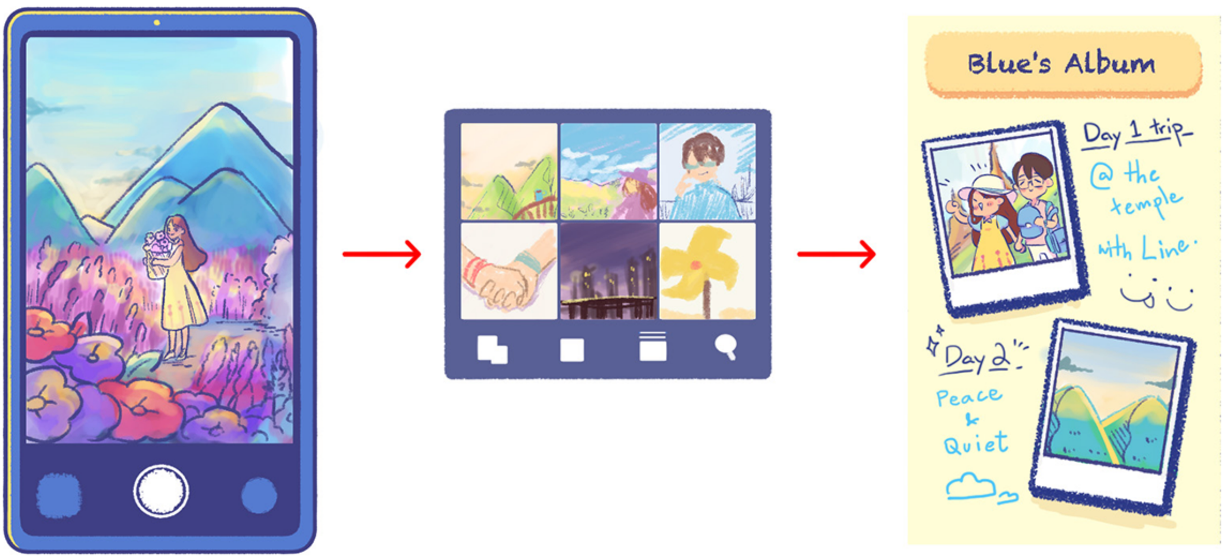


Figure 6. A breakdown of the conversation exchanged between Blue and Line in chapter 9 of BlueLine.

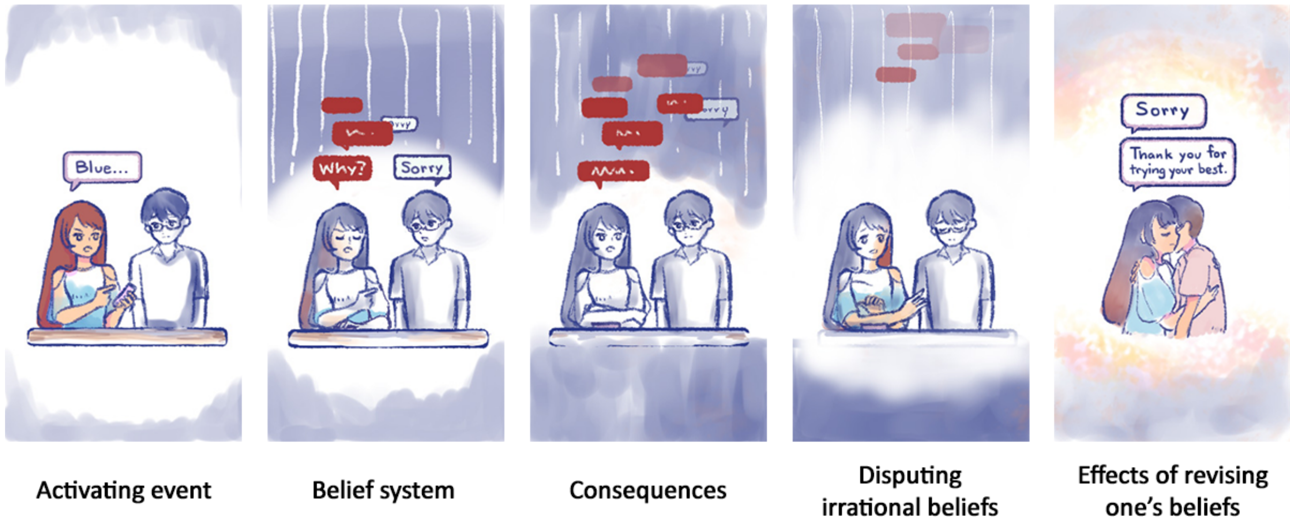

Discussion

Principal Findings

This study outlines the process of developing BlueLine, a gamified CBT intervention project on smartphones. BlueLine uses the ABCDE model as the game's core structure to present the gamified CBT components (Table 1). The core structure integrates the narrative structure before the gameplay with visual elements. The early development is iterative and experimental, and it involves collaboration with CBT specialists in Thailand who have expertise and knowledge in caring for Bangkok's millennials. Multiple playtests were set up with university students to help with the development process.

As a serious game, BlueLine falls into the visual narrative genre. Its gameplay lasts approximately 80 minutes, broken into 3 acts and 15 chapters. The game is split into short bursts to match a common habit of millennials—resorting to technology for a momentary escape from work—as well as their short attention span [71]. For the context to be meaningful to the target group, the daily routines, behaviors, and life experiences of Blue (the main character) reflect those of Bangkok's millennials. In addition, interactions in BlueLine are inputted using finger gestures that mimic those involved in the daily use of smartphones.

Primarily, we have designed BlueLine to be used in adjunct with the patient's primary treatment. It is not designed to tackle depressive symptoms entirely; instead, it focuses on enabling the player to understand the impact of depressive symptoms and learn how to lessen it. In most cases, our target group will not be playing the game while attending a session with their therapist; thus, BlueLine must be able to retain player engagement through gameplay. BlueLine's gamified CBT mechanics (narrative, verbal interactions, physical interactions, and social media interactions) have been created to be flexible enough to fit into many narrative contexts so that the game encourages repetitions of the following CBT techniques: behavioral activation, self-monitoring, interpersonal skills, positive psychology, relaxation and mindful activities, and problem-solving.

Strengths

Experience plays a crucial part in this project. Our members have experience making small-scale visual narrative games such as Yumi's Home [72], a first-person 2D narrative game about depression, familial obligation, and isolation. Furthermore, we have attempted to understand our target players and their behaviors in various ways. First, for 2 years, we were invested in researching the depressive symptoms experienced by Bangkok's millennials as well as preproduction prototypes. Second, the knowledge and experience of Thai CBT experts and the Department of Mental Health guided our design decisions in the development. There are 4 CBT experts, and each has >10 years of experience in psychotherapy; 2 experts are from the Department of Mental Health and a public psychiatric hospital, and 2 experts are faculty members of psychology departments at Thai universities. Thus, the project can scale up with confidence as we reach production.

To start with, we planned to localize BlueLine in both Thai and English. Those with Thai as their mother tongue can understand the nuances of the language and slang used by the characters, whereas English is meant for the increasingly international population in Bangkok. Players may switch the language at any given time via the options menu.

The story in BlueLine and the characters are based on the standard daily routines of Bangkok's millennials as well as the real-life stories of development team members. We have identified specific experiences that resonate through the spectrum of millennials' age range. The gameplay and visuals can be expressed on a deeper level in terms of attention to detail when non–game designers (artists and programmers) also participate in the design process [26].

Depressive symptoms can recur, and that is the takeaway from BlueLine, which shows players through interactions that CBT and therapeutic techniques can reduce the risk of relapse as long as it is maintained [51]. A game such as BlueLine is akin to an empathic listener. To empathize with another person is to understand their feelings, which is a level above mere acknowledgment. Serious games can make player more comfortable reaching out to the CBT-infused gameplay. Finally, BlueLine can enable players to learn by guiding the main character to challenge and overcome their dysfunctional beliefs.

Limitations

Currently, this project does not accept external funding. The project's scope is scaled to fit our current workforce, a team consisting of 5 members. Realistically, this is an ideal situation because we are able to maintain complete control over our design decisions. We intend all research and design processes to be free of external monetary influences (eg, investors). Once we complete the project, the app will be released in collaboration with the Department of Mental Health. We will consider a monetization model only after we have completed a randomized controlled trial of BlueLine with Bangkok's millennials.

Studies have shown the potential of gamification for depression care, but more data are needed to establish the effectiveness of this approach [73,74]. Many factors come into play when considering what gamification needs to accomplish in a serious game; each player may have different depressive symptoms, and the game cannot personalize the experience for each individual. An improper gamified element can have an adverse impact on individuals with mental illnesses [75].

Regarding game addictions, some studies have addressed their adverse effects on an individual's responsibilities (eg, education [76]) and personality (eg, adverse effects on self-esteem and behaviors [77]). In addition, BlueLine will be played on smartphones, which further extends users' total screen time. During the scoping phase, we established that the gameplay length is limited to <2 hours and is divided into small chapters to avoid long sessions. In the game, we have designed the interactions to be distinct from nonserious games and promote positive activities such as art therapy.

The BlueLine gameplay length of 1 hour and 20 minutes can be a little problematic, due to factors such as poor concentration, and can result in a higher likelihood of game addiction [44]. When a game loop is long, players can keep playing it repeatedly, which may result in long hours of screen time and addiction. However, BlueLine's *pause* and *resume* features allow players to take a break and return to the game later. In addition, it is within our scope to implement a feature to remind the player that they have been on the phone playing the game for too long. These features are used in internet-based CBT applications [46] and eHealth programs [47].

Of note, there are practical difficulties in developing mHealth apps in a higher middle–income country such as Thailand because of the lack of existing gamified mHealth apps for benchmarking. The lack of extensive statistical data on Bangkok's millennials makes it challenging to design specific scenarios in the game. To ensure that our design decisions can lead to the intended experience, we rely on creating multiple iterations of each scenario.

Growing up in Thailand, some of us have noticed that the general public, that is, those who belong to an earlier generation compared with millennials, have negative stereotypical misconceptions of games; they view games as childish activities and believe that a grown-up should not waste time playing games. Moreover, even today, seeking and receiving mental health care is stigmatized in many countries [78] and can lead to social rejection of patients as well as self-rejection experiences [79]. This aspect can hinder the reach of BlueLine to the target group. However, it is worth the attempt, considering the benefits of making CBT accessible to a substantial proportion of Bangkok's millennials. Thailand is one of many low- and middle-income countries looking at this technology as an opportunity [80].

Future Directions

In the future, we will collaborate with the Department of Mental Health to conduct a randomized controlled trial of BlueLine with Bangkok's millennials to assess its efficacy, acceptability, and usability. On the basis of the results, further adjustments will be made before BlueLine and its service avenues are completed.

Conclusions

In conclusion, the ABCDE model can be the structure of visual narrative games. The gamification of CBT and related therapeutic techniques are interchangeable based on the scenario and its intended experience for the player. To reinforce the same gamified combinations to the player while avoiding monotony in the gameplay, narrative context and visual representation can be used to retain player engagement through the game experience. However, BlueLine's development process is specifically focused on content related to Thai millennials; thus, its use may be less effective to other groups. BlueLine remains to be investigated in more detail regarding efficacy in adjunctive use with the patient's existing treatment in Thailand.

Acknowledgments

The authors would like to thank Thai cognitive behavioral therapy experts Dr Varoth Chotpitayasunondh; Dutsadee Juengsiragulwit, MD; Dr Somboon Hataiyusuk, MD; and Dr Somboon Jarukasemthawee, as well as Thailand's Department of Mental Health. The authors would also like to thank the members of the BlueLine team—Krittika Walaijai, Ratchanon Prapassornpong, and Kanitpong Tangtrongchit—for further stepping up their roles and the care they share for Blue and Line.

Conflicts of Interest

None declared.

Abstract

Background: Young people use digital technology on a daily basis and enjoy web-based games that promote social interactions among peers. These interactions in web-based communities can develop social knowledge and life skills. Intervening via existing web-based community games represents an innovative opportunity for health promotion interventions.

Objective: The aim of this study was to collect and describe players' proposals for delivering health promotion through existing web-based community games among young people, elaborate on related recommendations adapted from a concrete experience of intervention research, and describe the application of these recommendations in new interventions.

Methods: We implemented a health promotion and prevention intervention via a web-based community game (Habbo; Sulake Oy). During the implementation of the intervention, we conducted an observational qualitative study on young people's proposals via an intercept web-based focus group. We asked 22 young participants (3 groups in total) for their proposals about the best ways to carry out a health intervention in this context. First, using verbatim transcriptions of the players' proposals, we conducted a qualitative thematic analysis. Second, we elaborated on recommendations for action development and implementation based on our experiences and work with a multidisciplinary consortium of experts. Third, we applied these recommendations in new interventions and described their application.

Results: A thematic analysis of the participants' proposals revealed 3 main themes and 14 subthemes related to their proposals and process elements: the conditions for developing an attractive intervention within a game, the value of involving peers in developing the intervention, and the ways to mobilize and monitor gamers' participation. These proposals emphasized the importance of interventions involving and moderating a small group of players in a playful manner but with professional aspects. We established 16 domains with 27 recommendations for preparing an intervention and implementing it in web-based games by adopting the codes of game culture. The application of the recommendations showed their usefulness and that it was possible to make adapted and diverse interventions in the game.

Conclusions: Integrated health promotion interventions in existing web-based community games have the potential for promoting the health and well-being of young people. There is a need to incorporate specific key aspects of the games and gaming community recommendations, from conception to implementation, to maximize the relevance, acceptability, and feasibility of the interventions integrated in current digital practices.

Trial Registration: ClinicalTrials.gov NCT04888208; https://clinicaltrials.gov/ct2/show/NCT04888208

Introduction

Background

Health promotion requires the creation of health-enhancing public policy with diverse and complementary approaches, particularly in the face of public health challenges (chronic diseases, social inequalities, and health systems issues) [1]. In this sense, health promotion is defined as the process of enabling people to increase their control over and improve their own health [2]. Areas for action include creating supportive environments, strengthening community actions, and developing personal skills. Health promotion interventions must then consider the importance of community and social dimensions, mobilizing social interactions as a lever for population health [3]. These social dimensions can reduce risk factors and increase the well-being of individuals.

Youth is a major period of empowerment and life evolution, with the formation of identity, social relationships, new responsibilities, and a professional future. It is also a period marked by health issues [4] that health promotion can address [2]. To do so, public health actors must understand the population's concerns, habits, and culture to adapt their intervention strategies. Describing and understanding the characteristics of an identified group and studying its behaviors, expectations, and preferences enables the development of health actions with greater impact on the target audience and society [5,6].

Web-based games are attractive and widely used by young people, involving an environment in which players can explore, interact, and follow scenarios in association with characters and stories [7]. Games present relevant challenges for players who require different types of effort to solve tasks (ludic activities) or share experiences [7,8]. The "community" aspect of some web-based games means that, as in social network sites, players can connect with others, build web-based relationships, and find a "peer-to-peer" environment and support around common interests and shared game codes [9]. The community aspect can be centered on specific ages, lifestyles, backgrounds, or thematic characteristics such as interests, hobbies, pastimes, or games [9,10].

Some game-based health promotion interventions are promising, with positive results in terms of feasibility and short-term effects on knowledge and attitudes related to diet, physical activity, and lifestyle [7,11]. However, there is a need to address some key challenges in terms of the process and optimal conditions of implementation to understand how games can be the site of effective health promotion (intervention mechanisms) and research. First, researchers must describe the implementation means of such interventions. Poor conceptualization or bad implementation of an intervention can have a direct impact on its effectiveness [12]. To be effective, web-based games created for health promotion should include the following characteristics or features: feasibility, ease of use, storytelling, feedback, fun, and a proven focus on the health topic addressed [7]. In the case of web-based games that were not originally dedicated to health promotion and research, such data are missing.

The Scott project aimed to deliver a health promotion and disease prevention intervention via an existing web-based community game for young people. Indeed, our hypothesis was that intervening via popular games might enhance the acceptability (user-friendliness) and scope of our actions. The Scott intervention consisted of facilitating small-group health discussions in the game. We chose the Habbo game (developed by the video game company Sulake Oy)—a free, popular, and web-based game with social interactions in which it was possible to intervene.

Goal of This Study

On the basis of the Scott concrete experience, the aim of this study was to (1) analyze players' proposals during the implementation of the intervention in the Habbo game, (2) elaborate on researchers' recommendations for conducting a health promotion intervention in existing web-based community games among young people, and (3) describe the application of these recommendations in new interventions in the same Habbo game.

Methods

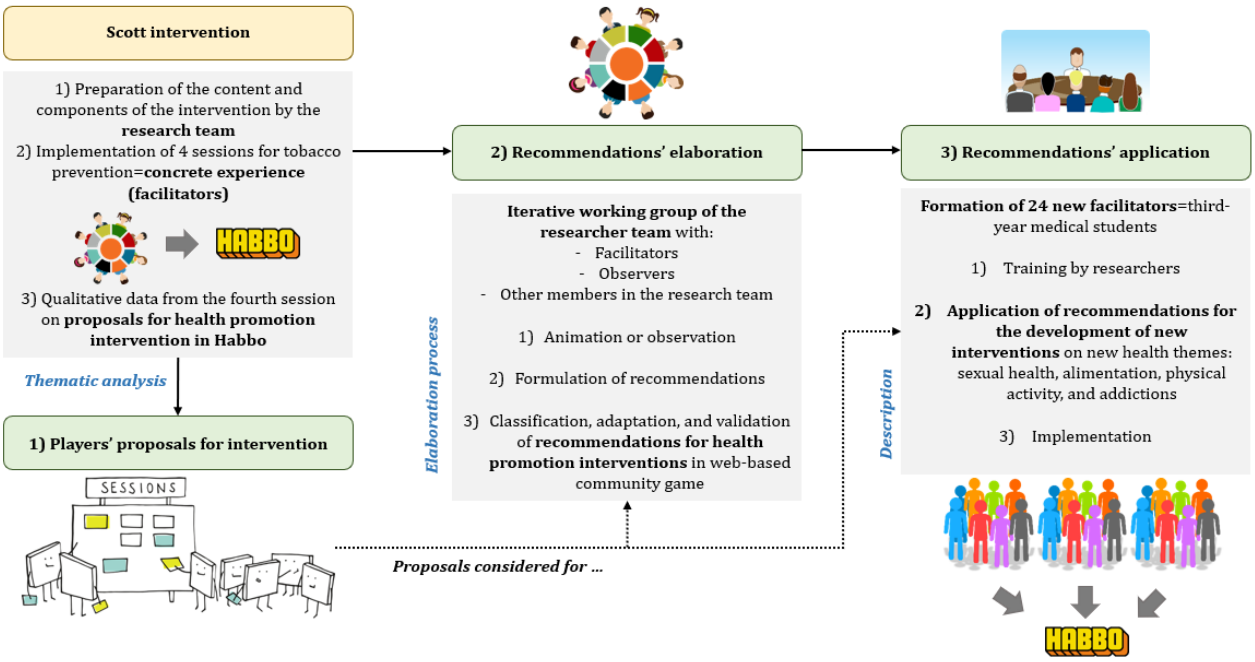
Overview

Our study is embedded in the Scott project, which is broadly a health promotion intervention research project aimed at implementing and evaluating an intervention in a web-based game. The first pilot study was conducted in 2020 [13]. The Scott project is registered on ClinicalTrials.gov (identifier NCT04888208).

During the implementation phase of the intervention, we conducted this qualitative study on the expectations and proposals of the participants in the first pilot study. Of all the pilot study participants, a panel of 22 participants were present to participate in the study.

We conducted a qualitative study nested in the Scott intervention implementation based on (1) a questioning of players' proposals for delivering health promotion within a web-based community game, (2) working groups with a multidisciplinary consortium of researchers for the elaboration of recommendations (based on our concrete experience), and (3) an application of these recommendations for new interventions in the same game. The stages and study processes are shown in Figure 1.

Figure 1. Stages and study process of the study.



Scott Intervention

The Scott intervention was a health promotion and prevention intervention, initially a tobacco prevention initiative, integrated into a popular web-based community game and thus targeting adolescent and young adult game players (the game is officially permitted to be played by an audience aged ≥14 years). During this experiment, we investigated players' proposals for pursuing health promotion within the game on any health themes.

Theory

The entire theoretical framework of the intervention is described in Multimedia Appendix 1 [14-20]. The theoretical framework is based on the notions of social support, group motivation, and social learning [21], as applied to small web-based groups [14]. The mobilized theories are the theory of planned behavior [15], social learning theory [16], peer education [17] (with a link between peer education and social learning theory [18]), and the notion of small-group behavior change in web-based communities [14]. The main premise is that group discussion fosters the development of collective motivation and sufficient knowledge, norms, and skills to promote favorable health behaviors.

Setting

We conducted the intervention in the French-speaking version of the web-based world Habbo. Habbo is an open-world web-based social network–type game with gamification elements. Habbo is a fun game with various activities with social interactions and different worlds in the game, allowing players to participate in discussion groups. The players can communicate with each other by sending limited character messages. The instant messages are limited to 50 characters. This results in many messages, a fast flow of messages, and multiple conversations in 1 space.

Ambassador players are players who are recognized for their attendance and good behavior. A team of moderators and a community manager ensure that the exchanges are fair. The developers of the Habbo game already allow external health actors to intervene in their game for health promotion interventions (not involving research) with the facilitation of the community manager and ambassador players. In the Scott project, we asked for the creation of a space in the web-based game (named a "room" inside the game) specifically for the project, with the appearance of a garden inside which a bus with a maximum capacity of 10 players (small group) was parked for the delivery of the intervention (Figure 2). A queue was set up to allow a limited number of participants to get access to the bus (10 players per session). We replicated the intervention framework of Fil Santé Jeunes (a French information service for young people [aged 12-25 years] in the field of health), which has been intervening in Habbo for several years. One of the research team members (CD) facilitated contact with Sulake and the transmission of needed experiences and skills. The relationship with Sulake was established entirely through the Habbo game's community manager. She helped us prepare the intervention (practical arrangements, recruitment, the dissemination of information notes, the implementation of the intervention, and the distribution of measurement tools).

Moreover, she acted as a unique intermediary between the developer and researcher, especially with regard to the following: the temporality of the intervention, the content of the sessions, questionnaires, data collected, and feedback.

Figure 2. Garden and bus for the project (place of intervention).

Facilitators

A pair of facilitators (PM and ELR) were in charge of the animation and moderation of action. This pair was composed of 2 public health researchers, identified in the game as woman and man, to ensure a gender mix. They had a pseudonym integrating the term "health" to assert their professional position.

Development and Preparation

We developed the intervention content with a pluridisciplinary research team consisting of prevention workers, a psychologist (already leading a support group centered on adolescents' issues in the Habbo game), the game's community manager, sociology and social marketing professionals, and researchers involved in health promotion and intervention research. Two researchers (the facilitators) were previously trained by one of the regular health professionals operating in the game, the community manager of the game, and 3 experienced players to facilitate the intervention. They were trained to test the game's commands (speak, exclude, silence, etc) before setting up the intervention.

Involvement of Peer Players

We worked with the ambassador players for the preparation of the first intervention (part 1) and application of the recommendations (part 3). These players were involved in the training of the facilitators (getting to grips with the features) and in the construction of the places of intervention in the game (Habbo players can create different spaces on the web).

In the game, players can collect badges (with no monetary value), which were used as incentives for this project. Badges were allocated to the participants before and after participation. To enhance novelty, we proposed the opportunity to create and provide original badges dedicated to this project (coconstruction vision) to some volunteer ambassadors.

Contents and Processes

We offered four 30-minute discussion sessions on 4 Thursdays in October 2020 at the proposed times of 11 AM, 3 PM, and 5 PM (12 sessions). We proposed different types of content concerning health issues and tobacco prevention (session 1: representations of tobacco, session 2: benefits of not smoking, session 3: resisting proposals from those around you, and session 4: helping others by making proposals for others' intervention). For the fourth and final session, we asked all 22 players (1 session per group; 3 groups=3 sessions) for their proposals and recommendations for pursuing health promotion actions in the game.

Participants

The participants were all volunteer French-speaking Habbo players. A preintervention survey was conducted in January 2020 to ensure that the average age of the given sample corresponded to that of a population of adolescents and young adults. Of the 83 responses, 75% (n=62) were from male participants, and the median age of the participants was 23 years, with a minimum age of 16 years and a maximum age of 32 years. The median age is in accordance with the World Health Organization's definition of young people's age range, which is 10 to 24 years [4].

Recruitment Process

We recruited study participants in October 2020. A week before the first session, we asked for a banner advertisement on the game's log-in page with all the information about the study (objective, facilitator's contacts, time, place, and subject). We also explained that not all players would be able to participate because of limited places and randomization. The participants were informed that they were participating in public health research. After inclusion, before the session integrating the qualitative study (session 4), the participants were informed that the purpose of this session was to collect their proposals for future interventions.

On the day of the first intervention, on the home page of the game, the participants had to fill in a questionnaire on baseline information (its completion constituted a criterion of eligibility for randomization). After the completion of the questionnaire, the participants were randomly provided either the intervention group badge or the control group badge. We planned 3 time slots for recruitment on the same day, at 11 AM, 3 PM, and 5 PM. For each time slot, a maximum of 10 participants received the intervention badge, which was valid for the 4 sessions (the day of randomization and the following 3 Thursdays). The control group, as well as the intervention group, had access to health information on preexisting websites posted in the project room.

Data Collected

Data were collected (1) from the qualitative study and the fourth session (focus group) on proposals, (2) from the working groups with a multidisciplinary consortium of researchers and feedback from the research facilitators, and (3) from observations of other interventions developed on the basis of the recommendations and applied by other facilitators.

1. Players' Proposals for Intervention

During the last (fourth) session, the players from the intervention group were asked about the attractiveness of the intervention and their proposals for health promotion in the game. We asked them to insert health promotion and prevention interventions into the Habbo game but beyond the Scott intervention. We asked the following questions: "Would you be willing to help us do prevention activities in Habbo? What would you consider important? What would you want to implement?" We collected verbatim testimonies from messages that illustrated players' proposals, elements of attractiveness, and the process of the intervention. No personal or identifying data (including pseudonyms) were collected for analysis. We collected the number of participants and number of messages sent during each session. Beyond these data, the facilitators collected personal feelings about the sessions, with field notes and points for animating and moderating interventions. We transcribed the participants' testimonies and associated them with a participant code (S1, S2, ..., Si) to preserve anonymity.

2. Recommendations' Elaboration

Iterative working group sessions were held among researchers (including facilitators) to share and analyze feedback from the intervention sessions and formulate recommendations for further interventions in the games. These data were in the form of raw notes and feedback reports.

3. Recommendations' Application

Three authors (PM, ELR, and CE) applied these recommendations during the training of new intervention facilitators in the same game. PM, ELR, and CE were responsible for training and supervising these facilitators. The facilitators were (third-year) medical students carrying out a practical initiation into prevention as part of their training. Eight different interventions over 2 weeks (4 per week), with 3 facilitators per intervention (24 facilitators [third-year medical students]) and new health themes (sexual health, addiction, physical activity, food, and nutrition), were developed. They conceptualized these new interventions based on the recommendations on diverse health themes, such as addiction, nutrition, sexual health, and physical activity.

Analysis

We conducted a qualitative analysis based on (1) the chat transcripts of the players, (2) a description of the recommendations elaborated by the researchers' working group, and (3) a description of the observation of the recommendations' application.

1. Qualitative Analysis of "Players' Proposals for Intervention"

We conducted a qualitative analysis of the participants' proposals regarding elements related to health promotion interventions: context, audience expectations, intervention components, and implementation modalities [22].

We conducted a thematic analysis focusing on the proposals and process elements related to the acceptability, attractiveness, and implementation of interventions in a web-based community game specifically. We allowed the participants' proposals to emerge during the sessions. The analysis was conducted based on raw proposals without predefined themes. The authors formulated proposals around the main themes and associated subthemes following these stages: initialization, construction, rectification, and finalization [23]. The initialization phase corresponded to the rereading of each session (thanks to the game's conversation history). The researchers EL and PM took notes on the emerging themes and their impressions. These 2 researchers then carried out the construction phase by classifying and describing the different expectations and proposals of the participants through a first classification and organization of the themes. For the analysis, we accumulated several messages from the same participant to relate all their proposals (only if they made several short messages in a row). The rectification phase corresponded to the distancing of the themes, notably by proposing them to the other researchers of the team, for adaptation and stabilization. This phase also allowed us to put forward the themes that brought real new scientific knowledge. Finally, the finalization phase focused on organizing the themes according to the link or distance between them (organization of the "storyline" of the proposals).

2. Recommendations' Elaboration

Following the intervention, the researchers provided feedback and developed recommendations for interventions specifically conducted in web-based community games. These recommendations were designed based on current recommendations for interventional research, on the experiences of the 2 researchers involved as facilitators (PM and ELR), and on the data from researchers who acted as observers during some sessions (BC, JK, and AD); discussed; adapted; classified; and validated by all the researchers associated with the project.

We analyzed domains and recommendations: the domains correspond to the important steps of preparation, conceptualization of the intervention, and realization of the intervention (implementation); the recommendations are concrete and detailed suggestions for how to meet the expectations for each domain.

3. Recommendations' Application

We observed and formulated a description of the recommendation-based interventions developed, centered on components and implementation modalities, to illustrate the concrete application of each recommendation.

Ethics Approval

The Inserm Ethics Review Committee and Inserm Institutional Review Board (IRB00003888, IORG0003254, and FWA00005831) provided a favorable opinion for our study and approved its information circuit on July 7, 2020.

Results

Overview

A total of 22 players participated in the session for the collection of proposals. Proposals were collected from groups of players (3 groups of 9, 8, and 5 players, named S1 to S22 in the following results), and 1715 messages were posted (an average of 572 messages per session), of which 1155 (67%) were posted by the participants and 560 (33%) were posted by the facilitators and researchers (PM and ELR). The facilitators and researchers (PM and ELR) who conducted the focus groups considered that the third group interviewed, in addition to the other 2 groups, provided no new information. Thus, they considered that data saturation had been reached.

Players' Proposals for Intervention

Thematic analysis of the participants' proposals revealed 3 main themes and 14 subthemes related to their proposals and process elements for health promotion action within the web-based community game. Textbox 1 presents these themes.

Textbox 1. Key themes and subthemes identified in the session.

Develop an attractive intervention in the game

- The need for varied and renewed health topics
- Entertainment components and formats for prevention
- Challenge as a motivation to participate
- An entertaining intervention that may be considered not serious enough
- The involvement of multiple stakeholders in the development and implementation of interventions

Involve peers in the development of the intervention in the game

- In favor of codeveloping the action
- Remaining anonymous for the fear of not being taken seriously
- Feeling of insufficient knowledge for delivering prevention themselves
- Experience as a skill for prevention
- Motivation and social support among peers as a lever for action

Mobilize and control gamer participation

- Limiting the number of participants to ensure the success of the action
- Trolls and essential moderation of exchanges
- In-game rewards as incentives
- Promote action outside the web-based game

Develop an Attractive Intervention in the Game

All the interviewed participants expressed an interest in contributing to the development of a prevention intervention in a web-based game. Through 5 subthemes, the analysis highlighted the themes, expected components, and formats, as well as the different stakeholders involved in the design and implementation of the intervention.

The Need for Varied and Renewed Health Topics

Initially, the participants mentioned the importance of addressing a variety of health topics. One of the participants (S2) suggested using a polling system to guide the topics addressed. Two participants mentioned the importance of including topics around “anything harmful” (S11) and health consequences by highlighting “impact features” (S2). One of the participants suggested a period for renewing topics, with “new themes each week” (S11).

Entertainment Components and Formats for Prevention

The participants proposed several action components, mostly participatory and interactive components, such as quizzes, games, and discussion groups (S11 and S12), to structure interventions. One of the participants (S11) explained the need to create places in the web-based game dedicated to prevention in the game, such as theaters or apartments. Another participant (S12) highlighted the importance of using animation and games as levers of participation:

> *There need to be animations and games. Those make it more engaging, and questionnaires are attractive too. You know, you can do everything and anything like that, with quizzes in the form of questionnaires.* [S12]

One of the participants mentioned the possibility of asking questions through a question box system (S11 and S12). Another suggested a system in which participants can ask questions through forums (S6). The same participant (S6) mentioned the possibility of introducing a prevention campaign in the game in connection with official institutional programs. Some also considered links to existing resources, with access to information summaries.

Challenge as a Motivation to Participate

One of the participants proposed a call for poster production in the form of a challenge to encourage the participants’ motivation and production:

> *...a poster competition within the game, with the results displayed in room galleries of the game.* [S8]

Another participant reminded us that there are already challenges in the game for players and that we only need to reuse this system for the intervention:

> *Actually Habbo has been doing competitions for years, so that means just re-using the same idea, and suggesting that players make a poster about smoking.* [S7]

In addition, one of the participants mentioned competitions with a prize to win:

> *Later we could set up animation games with a monthly ranking. For example, the top 5 players could be given a badge.* [S14]

An Entertaining Intervention That May Be Considered Not Serious Enough

When we asked whether an in-game prevention message is a good idea, we were told the following:

> *I am not sure, Philou [the facilitator], maybe they won’t take it very seriously.* [S3]

A participant (S1) warned that playful or entertaining elements may not lead players to consider the prevention message integrated into the action:

> *I think [the over-entertaining aspect of the prevention game] may be completely counter-productive and undermine the message it is supposed to convey.* [S1]

The Involvement of Multiple Stakeholders in the Development and Implementation of Interventions

When asked about the technical development of the action, some participants mentioned the help of the community manager, present and known to all. She is the one who grants permissions and accompanies the creation of new elements of the game. She would have the task of explaining the course of a multicomponent action (S12):

> *So organize animators let’s say once a week in addition to a discussion, with that a monthly ranking, with ‘the question box’ for the follow-up...the news of the community manager to explain the whole system.* [S12]

More generally, the participants suggested involving several actors in the game for intervention: the community manager, the health professionals, and the player ambassadors (S1, S12, and S14):

> *I think one of you two [facilitators] should be involved, with a Habbo representative, a player, and with an event on the welcome page. That makes it a real thing that’s being organised.* [S14]

As a result, the interviewed participants showed a willingness to take action with their fellow players.

Involve Peers in the Development of the Intervention in the Game

The thematic analysis highlighted the community dimensions within the game that can be levers of attraction to preventive action. These elements were organized into 5 subthemes.

In Favor of Codeveloping the Action

Most participants expressed a willingness to contribute to the development of preventive action within the game. Their role can be that of being a peer advocate or peer educator:

> *If it can have an impact on other people and can help them, I would be very happy to take part…I would hope to be able to take part or be a facilitator, to interact with the players and in fact help them with topics.* [S2]

Remain Anonymous for the Fear of Not Being Taken Seriously

If they were to be involved as peer educators in delivering actions, 3 participants (S8, S12, and S14) mentioned the need to be anonymous with a different pseudonym or avatar. Not being recognizable as a classical player would make other players listen to them more. One of the participants explained the need for a professional presence to be taken seriously:

> *In fact the worry is that if there are no professionals with us the players won't take us so seriously, because we know each other.* [S12]

Indeed, some are well known by their game peers, and it would be difficult for them to be taken seriously:

> *On the other hand if I appeared as a clone that would be fine, because I wouldn't be recognized. So long as there is anonymity I have no problem.* [S14]

Feeling of Insufficient Knowledge for Delivering Prevention Themselves

Beyond the players' self-projection as prevention actors, one of the participants emphasized his feeling of not being able to intervene on all health issues:

> *I don't feel I am capable of making a judgment about everything.* [S13]

He also pointed to his lack of experience in talking about certain topics:

> *Personally I don't think I am the best person [to do smoking prevention] since I have never smoked.* [S13]

Experience as a Skill for Prevention

Participants mentioned that experience then intervenes as a skill that can be mobilized by the players or professional facilitators (S1, S12, and S15):

> *Yes, when it's doing adapted prevention, which can also bring out your personal experience of the subject.* [S1]

> *...with people who have been affected by the subjects being discussed perhaps.* [S15]

> *I am not a good example although being a smoker myself I know all about the downsides.* [S12]

If mobilized for delivering prevention messages, a participant reported that his point of view would be more intelligible and impactful:

> *Our personal experience will make it more impactful...I would have more to talk about and have more impact in what I say.* [S2]

Motivation and Social Support Among Peers as a Lever for Action

For a participant (S6), the involvement of peers could take place through a social support system between gaming peers through sponsorship, similar to existing support strategies outside web-based games:

> *We could do it like our counterparts for alcohol, except that we are on Habbo...Yes, the units could be a series of badges and they can be used as tokens, like for alcoholism.* [S6]

This peer-to-peer social support can lead to web-based group challenges, such as the community challenge mentioned by one of the participants:

> *One could also think about a community challenge with ranking results.* [S8]

However, another participant (S11) highlighted the difficulty of motivating and mobilizing other players through digital means, especially for prevention:

> *Well, yes I would be happy to help someone stop smoking, but it's tricky sitting with a PC, isn't it?* [S11]

Mobilize and Control Gamer Participation

Beyond the involvement of web-based gaming peers as peer educators, the thematic analysis highlighted the ways in which players (the target audience) are engaged in prevention. In this regard, 4 subthemes were highlighted.

Limiting the Number of Participants to Ensure the Success of the Action

The participants expressed that it is more pleasant to play the game in small groups:

> *Yes, it's more pleasant in a small committee.* [S12]

Several participants emphasized the need to think about a prevention action that would mobilize small groups in the game (S2, S4, S5, and S12), especially to be able to debate properly (S2). One of the participants (S5) suggested limiting the number of participants to 10, always with 2 facilitators. It was also pointed out that several sessions are necessary (S2):

> *With a big group (100) it's likely to be more difficult because there will always be people to disturb others who really want to pay attention.* [S2]

> *I loved the once-weekly format.* [S14]

Trolls and Essential Moderation of Exchanges

Many players also talked about disrupters within the game (trolls). One of the participants said that there will always be "those who distract people who want to listen" (S2). A participant indicated that moderation is mandatory for the proper conduct of the action:

> *It's obligatory, Philou, you were in luck here, but in the bus there are usually trolls.* [S1]

This participant considered ambassadors (players with good behavior in the game) as people who could support this moderation:

> *with one or two ambassadors to moderate the players who come to provoke everyone in your INSERM sessions.* [S1]

In-Game Rewards as Incentives

The participants discussed how to reach players and enroll them in prevention action. Some participants (S1, S9, and S10) indicated the importance of rewards for engaging players:

> *To be very frank with you, if there aren't any rewards to be had, and it's just for prevention...you won't get many followers.* [S9]

The same participants pointed out that in the game, "badges" are collectibles and that many players want to acquire them:

> *Those who win get a badge, players really like badges.* [S6]

> *Then I also think there has to be a badge for each session depending on the theme (people will be more receptive).* [S1]

However, 2 participants (S3 and S11) suggested that players who come only for the incentives (badges) would be less influenced by the prevention action:

> *Many of them will come just for the badge.* [S3]

> *It's true that if there are incentives to win there will be more players, but we don't want them to come just for the badges.* [S11]

One of the participant (S12) expressed that not implementing these incentives would be a way to select the most motivated individuals:

> *Those who are prepared to attend knowing there is nothing to win are sure to be the most sincerely motivated.* [S12]

Promote Action Outside the Web-Based Game

A participant indicated the importance of taking action beyond the game, especially to reach more people:

> *To be honest, Habbo is not the way to mobilize the most people, you need to aim higher.* [S7]

Another way to get players to participate in action would be to promote the action inside and outside the game among the Habbo community (on Twitter [Twitter, Inc] and fan websites). One of the participants suggested putting billboards about the prevention action in the game (S2). Another participant (S11) suggested that the community manager could advertise on the game's home page and through alerts.

Yet another participant suggested recording the actions to replay them and reach more people:

> *in a public space in the game, with the Habbo viewing experience. Film it and replay it on fan sites [for fans outside the Habbo game itself].* [S1]

Another participant (S6) mentioned that the social networking site Twitter and game-related accounts can be used to advertise the action:

> *You can do ads on Twitter, on the Habbo news site, and in the bus you can work on themes around addictions like cigarettes.* [S6]

Recommendations' Elaboration and Application

Following the analysis of young people's proposals and professionals' experiences, we established 16 domains of 27 recommendations for health intervention in existing web-based community games (Multimedia Appendix 2). Each illustration describes the application of each recommendation during the development of new actions introduced in the game. Thus, Table S1 in Multimedia Appendix 2 integrates the fields, recommendations, applications of the recommendations in new interventions, and descriptions of specific new interventions. Multimedia Appendix 3 describes the interventions developed in response to these recommendations.

Discussion

Principal Findings

Our study highlights Habbo players' proposals for developing interventions within the web-based game. These proposals emphasized the importance of serious interventions that need to involve and moderate a small group of people in a playful way. Using a reflexive approach, we also proposed recommendations for application in different interventions in general web-based community games. These recommendations highlight numerous suggestions for preparing and implementing an intervention, correctly incorporating it into web-based games, and adopting the codes of the web-based community game culture.

Meaning of the Findings

Our study showed that it is possible to work in fields that are not commonly explored and exploited by intervention research, with important recommendations for making good use of them. This study shows that it is possible to integrate the intervention into games that the target population already plays instead of creating a new game for a health intervention. We knew that it was possible to intervene in the game (following the Fil Santé Jeunes experience). Nevertheless, this study wanted to delve further by collecting concrete proposals from the players. Recommendations based on the Fil Santé Jeunes experience completed these proposals. This made it possible to bring together the contributions of various stakeholders (target population and professionals) via a participatory research approach [24,25].

The players indicated the importance of addressing a variety of health topics, that is, being responsive and diverse in health promotion responses. The study participants highlighted the importance of addressing many of the associated themes in health promotion action in a web-based game. More generally, a large number of web-based games are used for individual health, mainly for cognitive training or indirect health education [26], physical activity [27], managing chronic disease [28], preventing bullying [29] or preventing tobacco use [30]. Health actors have developed a very large number of games, and these games are generally novel interventions delivered to individuals, with different degrees of acceptability, attractiveness, and feasibility.

The participants highlighted the need for different types of involvement (the involvement of peers and facilitators) and ways to conceptualize and implement interventions for health. Web-based games can play a major role in the adoption of positive health behaviors, particularly because they promote players' self-esteem, provide support and information, and facilitate interaction and communication [28] with a sense of community. The world of games can be a real support. For example, avatars are important among young people as an extension of the self or as a way to further experiment with social relationships safely. A previous study has shown that among trans or gender-diverse youth, the use of an avatar facilitates the expression and consolidation of gender identity, with powerful mental health benefits [31].

We proposed several recommendations on how to act in existing games, including the consideration of participants at several levels: personalization, solicitation, animation, and moderation. Furthermore, in the field of mental health, Fleming et al [32] made the following recommendations for using web-based games for interventions [32]: a user-centered approach requiring exploration of group preferences, engaging and effective interventions with a description of game dynamics, cross-sectoral and international collaborations to seek out and identify the skills required for game development, and rapid testing and implementation to keep interventions engaging.

From our perspective, we highlighted new elements to intervene in already existing web-based games. Nevertheless, the literature still has a few examples of interventions integrated into existing games that are popular with the target audiences. Few studies have focused on the added value of using games rather than creating them, whether in response to health issues or economic issues related to development [33]. One of the studies, however, highlighted the use of existing commercial video games as therapies, studying these games as potential health interventions [34]. Colder Carras et al [34] noted that there is a lack of research on the use of commercial games for health and highlighted the need to design standardized protocols, study best practices to identify which games work on which health conditions, and model the complex and dense data of games. In the future, it will be possible to understand the effectiveness of actions integrated into web-based games for health promotion by considering the influence of action implementation and processes in web-based community games.

Implications for Decision Makers and Practitioners

Decision makers and initiators of health promotion interventions must consider several approaches to intervene through web-based games beyond the community aspects described in this study. It is necessary to consider that it is possible to intervene by 3 means: fitting the intervention into an existing game, creating a game specifically to intervene, and reusing a game without modification.

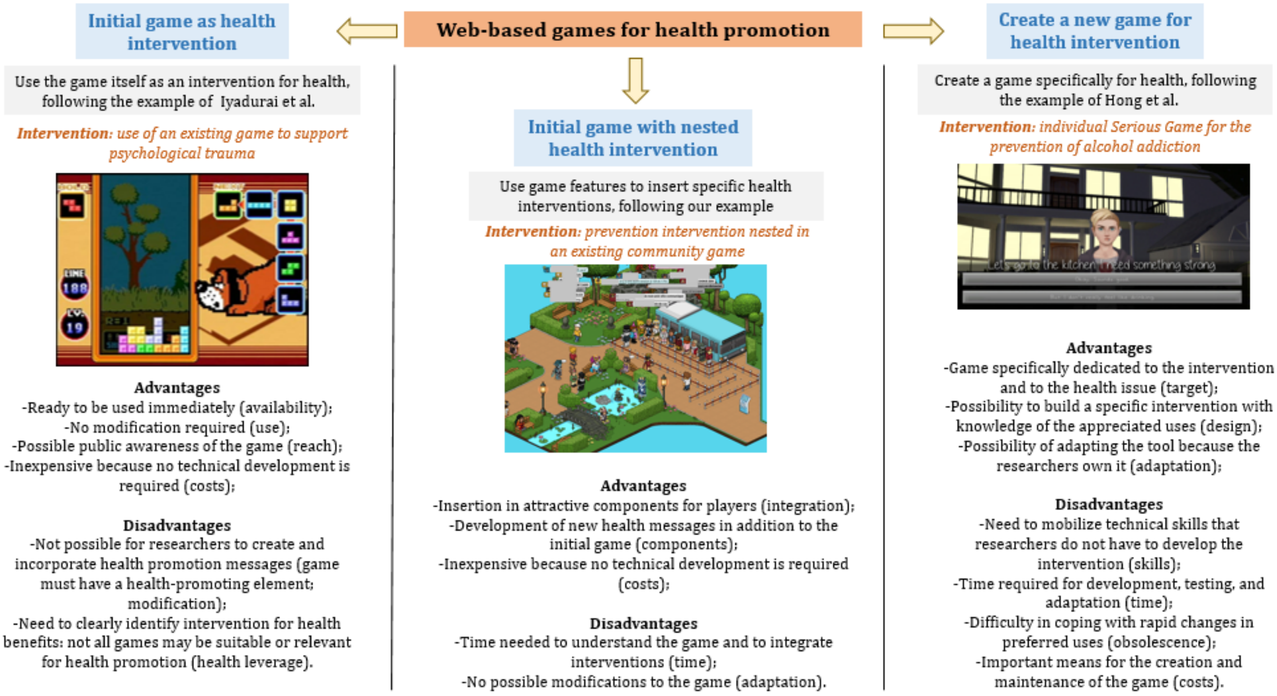
For interventions in existing games, it is necessary to consider what is practically possible (the potential of action). It remains necessary to understand the game's functioning to provide adapted interventions (functioning and adaptability). Some games do not allow for this kind of intervention because there is too strong a difference between the game objectives or gaming companies' culture and health objectives (real feasibility). If an intervention is possible, it is necessary to acculturate the intervention to the codes of the game without modifying the game. This requires the training and adaptation of external stakeholders (acculturation). Moreover, intervening in a game is only possible if there is a good link between the developers and stakeholders. It is important to establish a strong and trusting relationship with developers, particularly to integrate interventions in games (relationship). This relationship should also be considered from a research perspective, as it involves considering the data to be analyzed beyond the intervention to be implemented. On the one hand, the researchers must present to developers the real issues of research and the importance of collecting data that can be analyzed according to sometimes rigorous and complex methodologies (such as randomized controlled trials). On the other hand, the developers must explain how the game works (in a way that does not have health promotion as its initial goal) to anticipate both the best potential for action and the way in which the research can be carried out (eg, acceptability and accessibility of participants' data).

To develop a game for a health promotion intervention (similar to Hong et al [35]), it is essential to consider the levels of involvement needed. It is important to consider the need for technical skills to develop and maintain the game (technical skills). It is also important to consider the costs inherent to development and maintenance (costs). Moreover, it is essential to understand the uses of, expectations for, and attractions of the games (understanding), particularly the benefit of creating a new game (innovation). Developing a web-based game also takes time, with the risk of obsolescence of the game in the face of rapidly changing preferences (temporality and obsolescence). Creating a web-based game for health also raises the issue of reaching target audiences, who are already engaged with existing games.

According to the example set by some research [36], a third mode of intervention could be the replay of a web-based game as it is without inserting health content or even modifying the game's functionality. Although this would be inexpensive, it would require a clear identification of the actual health benefits that an unmodified, commercial web-based game could provide. The integration of these games with offline health practices or services is also generally required. These 3 modes that we discussed are illustrated in Figure 3.

In general, it is important for stakeholders to know which strategy is the most relevant to the target population, considering its accessibility and expectations (realism). The health intervention may have objectives that allow incorporation into existing games or require the creation of new web-based spaces. In any case, it is important to consider the implementation stages, stakeholders' roles (positions), and way to integrate populations. Incentives, elements of web-based games that can promote participation, can be used to integrate populations (incentives). In our experience, badges were attractive. The accomplishment of tasks and its valorization in game are sources of motivation for participation. For example, compensation with game's money can be discussed.

Figure 3. Illustration of the different possibilities to intervene through web-based games (Hong et al [35] and Iyadurai et al [36]).



Strengths, Limitations, and Future Directions

Our study is one of the few to investigate the potential of existing web-based community games for health promotion. It provides concrete methodological recommendations for the conceptualization and implementation of health actions in existing games. However, this study has limitations. We consulted the participants who were involved in our intervention, as the questions asked in this study occurred in the fourth session of the intervention, inducing a selection bias and not reaching the most distant players. In fact, we do not have information about the preferences of those who are more difficult to reach in the game. However, we collected the opinions of the most motivated players; they discussed the attractive elements of intervention for all players and how to develop and implement interventions for the most distant players. We developed our recommendations on 1 kind of web-based game (community based, with the possibility of development of elements in the game by the players).

We developed recommendations according to a structured methodology based on the experience and analysis of the project researchers. This methodology and the application of these recommendations in the development of new interventions demonstrated the internal validity of the recommendations. Recommendations must nevertheless be tested and validated in other games of this type, by other facilitators, with other intervention components, and for other health issues. Furthermore, the various functionalities offered by different web-based games require tempering the application of certain recommendations. Indeed, in our case, the game is mainly a place of web-based social interactions with gamification elements. Other web-based games might have features that are less community based. Therefore, our article focused on web-based community games with a socialization purpose. In addition, some of the recommendations may also be applicable outside existing games—not only to the development of new community health games but also to interventions using facilitation, communication, and participation techniques for health promotion.

Future research must continue to understand the processes involved in this type of intervention, depending on the audience and health issues being addressed. Indeed, interventions in web-based games can vary by topic (eg, differences in appeal between tobacco and mental health actions and differences in behavior change theories) and by participating audiences. It is still important to understand which population is using different popular web-based games to better understand whom we are reaching and what efforts need to be made. Knowing which population is attracted to health promotion activities remains important. Integrating target audiences (young people) into research processes remains essential in a community-based participatory research approach [24,25]. This will enable a better understanding of how to adapt and develop acceptable and attractive health promotion interventions in web-based games. Finally, research must involve evaluations based on complex intervention research recommendations to measure the effect of health promotion interventions in games on health determinants targeted by researchers and actors (information, attitudes, skills, and behaviors), taking into account context effects. To do this, the methodologies must be designed in an interdisciplinary manner and be based on existing recommendations [12,37].

Conclusions

Health interventions integrated in existing web-based community games represent a potential for promoting individual health and well-being. It is necessary to adapt to the changing preferences and uses of target populations by thinking of innovative means for intervention research (levers, brakes, and costs). This also requires a permanent acculturation of the interveners and researchers to correctly intervene and analyze the games as a place and potential for health promotion among the target audiences. Involving these audiences is of considerable help in designing and implementing innovative health promotion interventions.

Acknowledgments

The authors thank the Institute for Public Health Research for funding this study; the members of the Scott project for their contributions to the project, especially Bruno Giraudeau, Laëtitia Minary, and Anita Burgun; and Fil Santé Jeunes for their hospitality and training in good practices for conducting actions in the Habbo world. They particularly thank the community manager (anonymity preserved) for her indispensable support and the common management of this intervention. Finally, they thank the Habbo players for their opinions and advice on how to improve health promotion actions in web-based games, their translator Duncan Fulton for proofreading the manuscript, and the members of the Inserm U1123 and CIC-EC1426 teams for their support in the conduct of this project.

Authors' Contributions

ELR and PM wrote and submitted the protocol for the approval of this study. All the authors participated in the development of the intervention content. ELR and PM implemented the Scott intervention and collected the study data. CE, ELR, and PM applied new intervention sessions based on the recommendations. All authors participated in the analysis, generation of recommendations, application of the recommendations, and writing and validation of the manuscript.

Conflicts of Interest

Abstract

Background: After the COVID-19 pandemic, society has become more aware of the importance of some basic hygienic habits to avoid exposure to pathogens transmitted via hands. Given that a high frequency of touching mucous membranes can lead to a high risk of infection, it is essential to establish strategies to reduce this behavior as a preventive measure against contagion. This risk can be extrapolated to a multitude of health scenarios and transmission of many infectious diseases. #RedPingüiNO was designed as an intervention to prevent the transmission of SARS-CoV-2 and other pathogens through the reduction of facial self-touches by thoughtfully engaging participants in a serious game.

Objective: Facial self-touches should be understood as behaviors of limited control and awareness, used to regulate situations of cognitive and emotional demands, or as part of nonverbal communication. The objective of this study was to ensure that participants become aware of and reduce these behaviors through a game of self-perception.

Methods: The quasi-experimental intervention was applied to 103 healthy university students selected by convenience sampling and put into practice for 2 weeks, with 1 control group (n=24, 23.3%) and 2 experimental groups (experimental group with no additional social reinforcement interventions: n=36, 35%; experimental group with additional social reinforcement interventions: n=43, 41.7%). The objective was to improve knowledge and perception and reduce facial self-touches to prevent exposure to pathogens transmitted via hands not only in health multihazard scenarios but also in ordinary circumstances. The ad hoc instrument used to analyze the experience consisted of 43 items and was valid and reliable for the purpose of this study. The items were divided into 5 blocks extracted from the theoretical framework: sociological issues (1-5); hygiene habits (6-13); risk awareness (14-19); strategies for not touching the face (20-26); and questions after the intervention (27-42), designed as a postintervention tool assessing the game experience. Validation of the content was achieved through assessment by 12 expert referees. External validation was performed using a test-retest procedure, and reliability was verified using the Spearman correlation.

Results: The results of the ad hoc questionnaire, which were analyzed using the Wilcoxon signed-rank test and McNemar index to identify significant differences between test and retest for a 95% CI, showed that facial self-touches were reduced (item 20, $P<.001$; item 26, $P=.04$), and awareness of this spontaneous behavior and its triggers increased (item 15; $P=.007$). The results were reinforced by qualitative findings from the daily logs.

Conclusions: The intervention exhibited a greater effect from sharing the game, with interactions between people; however, in both cases, it was helpful in reducing facial self-touches. In summary, this game is suitable for reducing facial self-touches, and owing to its free availability and design, it can be adapted to various contexts.

Introduction

Background

The global pandemic caused by COVID-19 forced the World Health Organization and health care authorities to establish a series of fundamental measures to prevent the spread of infection, which have modified social behaviors [1,2]: social distancing, use of masks, frequent handwashing, and avoiding touching the face. Although the available epidemiological data and studies on environmental transmission factors have not defined fomite-mediated transmission through hand contact with the mucous membranes of the facial T-zone (eyes, nose, and mouth) as the main route, the risk of infection via this route by SARS-CoV-2 and other pathogens remains, as revealed by Marquès and Domingo [3], and rapid and direct recontamination can occur despite handwashing [4,5]. The survival of SARS-CoV-2 and other pathogens on surfaces is not known with accuracy, but we can take the influenza virus as a point of reference, which can survive for up to 10 minutes on our hands [6]. We can touch the mucous membranes of our face every 2 minutes [7], with a self-touching frequency of up to 50.06 times per hour [8], especially on the mouth, followed by the nose and eyes [9]. The frequency of hand-to-face contact shows great diversity; appears to be context dependent; is influenced by cognitive, attention, and emotional demands; and exhibits substantial individual and locational differences. It is difficult to establish an average [5,10], but given that a high frequency of touching the mucous membranes can lead to a high risk of infection, it seems essential to establish strategies to reduce this behavior as a preventive measure against contagions [11-13]. More importantly, this risk can be extrapolated to a multitude of health scenarios and the transmission of other infectious diseases.

Spontaneous facial self-touches (sFST) are defined as touches on one's own body, from the hands to the face, which include movements such as rubbing, scratching, stroking, or leaning on the hands, and which involve a proprioceptive activation of joints, muscles, and connective tissue, being able to activate skin sensitivity in a more or less conscious way, as pointed out by Spille et al [12]. These authors emphasize the importance of different triggers of sFST, distinguishing self-touches by self-regulation in situations where complex cognitive processes occur; by regulation of the intensity of emotions (anxiety, tension, clumsiness, uncertainty, discomfort, pleasure, and surprise); and finally, by the manifestation of emotions not expressed through words, which can be understood from nonverbal communication. Thus, we grouped the triggers of sFST by distinguishing compensation touches (as a manifestation of underlying emotions to adapt to a given context); warning touches (with prior warning such as itching, perspiration, tingling, hair brushing, imperfections, or lacrimation); and communicative gestures (without prior warning, with a triggering situation, and learned gestures, such as a hand on the chin while listening or waiting).

To reduce sFST, we can apply heuristics through specific interventions by avoiding errors of omission with signals and reminders; emphasizing the use of "if-then" plans; applying substitute or alternative behaviors; and developing an adequate and progressive reorganization of the brain [14], a process that requires observation and becoming aware of the trigger from a conditional strategy [15]. It could also be treated by consciously learning each touch action; differentiating it from its usual response chain; and replacing it with another action [16], such as using a handkerchief or touching another area of the face that is not a mucous membrane. In summary, the leading techniques for changing habits and behaviors seem to be repetition, the use of instructions and signals, action planning, the provision of instructions regarding how to carry out the behavior, and the establishment of behavioral objectives in the search for these self-control behaviors.

Objectives

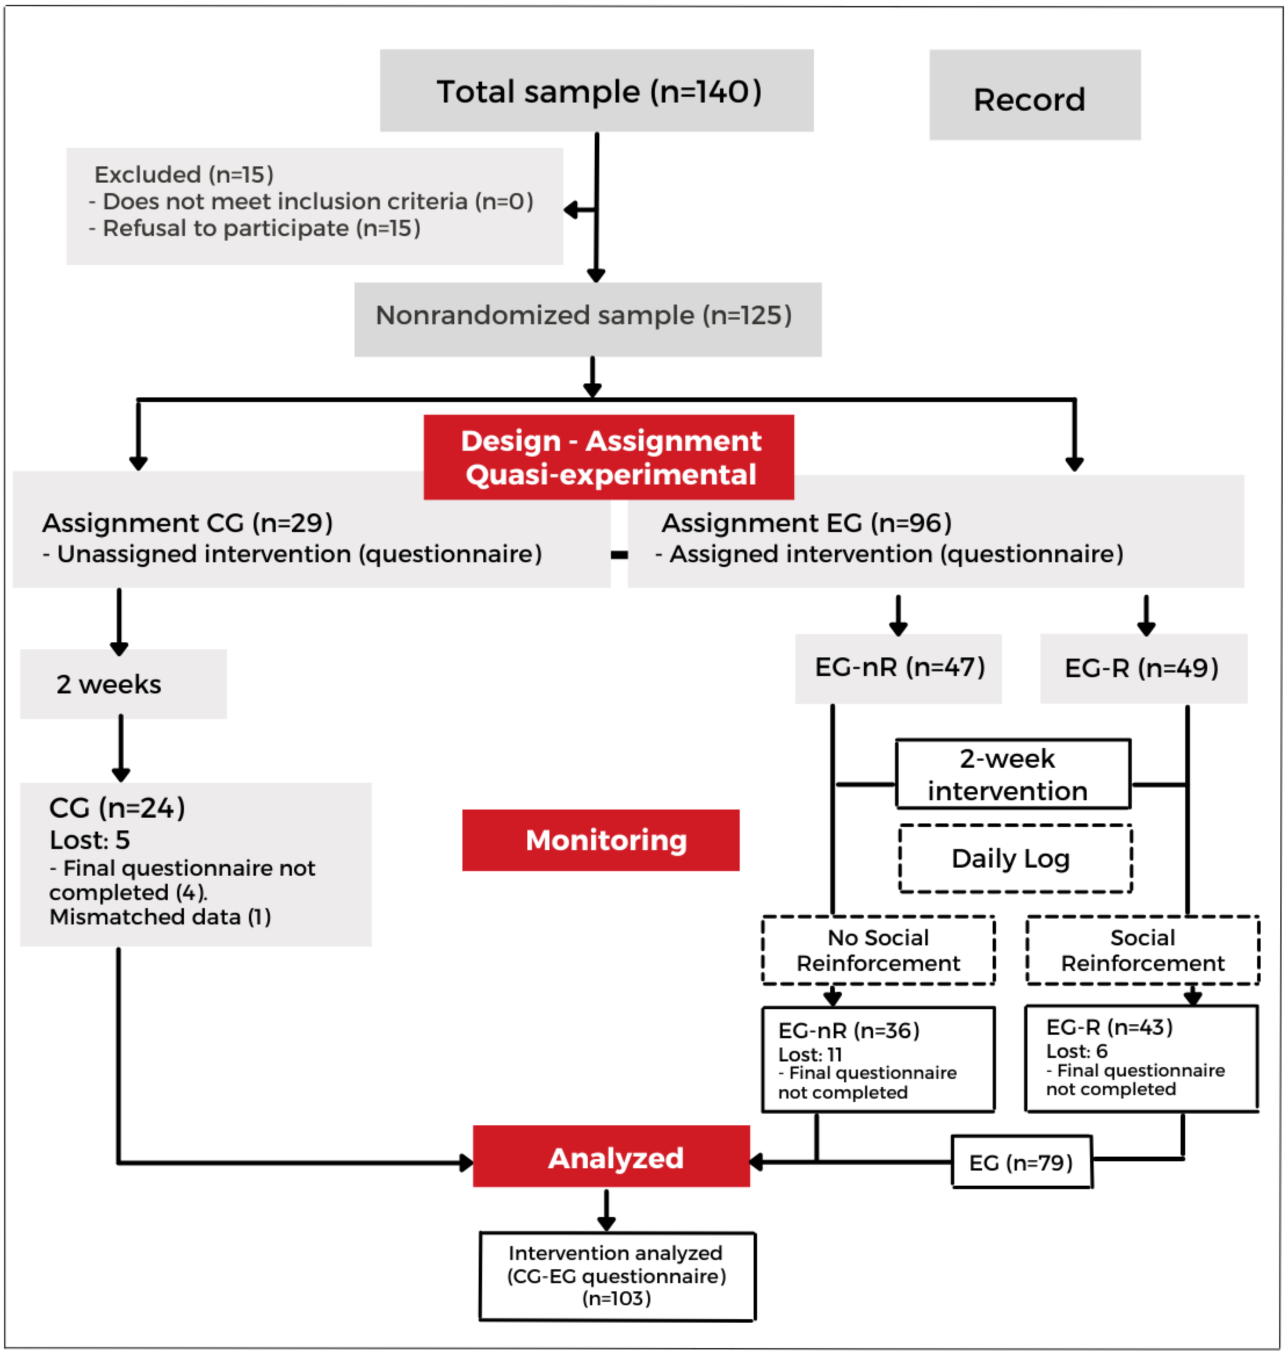
This study was based on the serious game. This concept is understood as a carefully planned playful framework, the main purpose of which is to provide not only the entertainment itself but also an engaging context that involves people who are playing in the learning process [17-19]. Research has resorted to the use of serious games to address health care content, in the context of training, preventing disease, rehabilitating, or seeking to improve quality of life and well-being [20-22]. A serious game like the one analyzed in this study is a tool with complex development but simple intervention, which favors its use in various contexts, such as health institutions, hospitals, community centers, schools, or similar entities, and by the entire population, adapting the research procedures and design to the characteristics of the participants. This intervention does not require complex procedures, tools, techniques, or specialized software; therefore, it is accessible, efficient, and possibly helpful in reducing and perceiving the behavior of not touching the face. The #RedPingüiNO methodological proposal is an intervention based on a serious game with the main objective of reducing facial self-touches as a preventive measure against exposure to pathogens transmitted via hands, such as SARS-CoV-2 and others. The foundation of its design is underpinned by the multidisciplinary theoretical framework, focused on a playful, engaging, and viral proposal that uses metaphors, humor, and a scoring system as drivers of the proposed game, using digital resources designed ad hoc that can be adapted to different contexts. Therefore, the objective of this study was to analyze the effects of the #RedPingüiNO intervention on the awareness and reduction of facial self-touches, especially in the T-zone, based on self-perception, given that a serious game seeks to positively impact the habits of participants.

Methods

Research Design

To design the research and the serious game, we have used Game-Based Intervention Reporting Guidelines given by Warsinsky et al [23]. Guidelines on conceptual issues, contributions of the study, related concepts, and definitions were taken into account; serious games were defined (*Introduction* section), the research stream was described (*Methods* section), the contribution of this study was clarified (*Discussion* section), and only core concepts based on the extant literature were used throughout the text. This study used a quasi-experimental design of involving a nonequivalent control group (CG) and a mixed approach. It is not possible to guarantee random assignment of the participants to the groups, but the educational center provides a predetermined distribution, ensuring limited homogeneity. This methodology is suitable for studying the potential causal effects of an intervention in open situations. The flowchart of the intervention is presented in Figure 1.

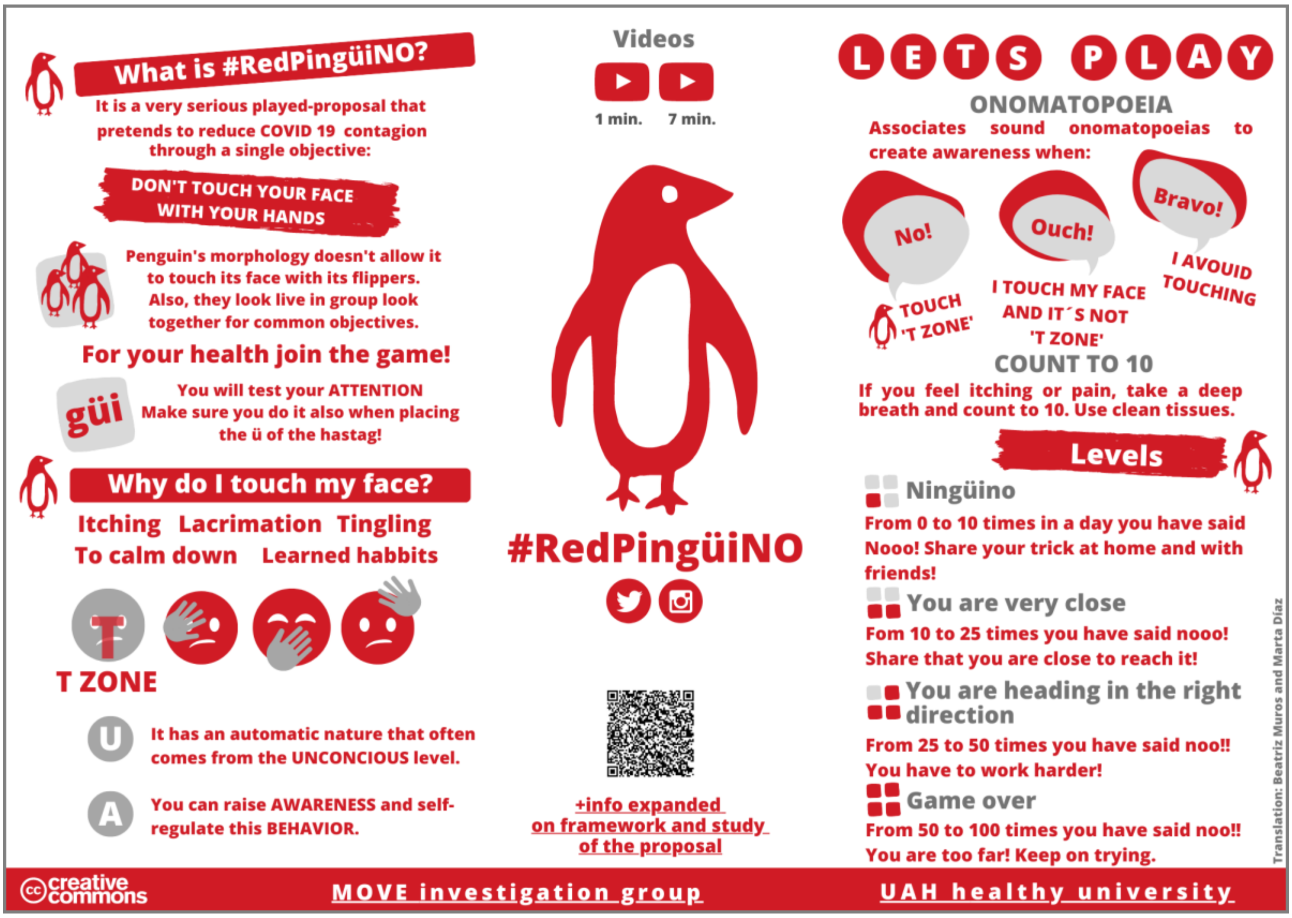
Figure 1. Flowchart of the intervention. CG: control group; EG: experimental group; EG-nR: experimental group with no additional social reinforcement interventions; EG-R: experimental group with additional social reinforcement interventions.



Serious Game Design

#RedPingüiNO is a project based on a serious game that aims to reduce the spread of COVID-19 and other diseases through strategies to avoid the act of touching the face with one's hands. The game uses penguins as protagonists because of their anatomy (they cannot touch their faces with their hands) and their social nature (collective and community behavior). The intervention platform has materials available in 8 languages. The game consists of associating sound onomatopoeias with behaviors: "No!" if the T-zone of the face is touched; "Ouch!" if another part of the face is touched; and "Bravo!" if the face is not touched at all. Descriptors and rankings are presented based on the daily frequency of self-touches (Figure 2). The rules of #RedPingüiNO were published on the #RedPingüiNO website [24].

Figure 2. Infographics and #RedPingüiNO website.



Participants

A total of 125 students taking the Primary Education Teaching Degree course from a public university in Madrid participated in this research. The sample was selected by convenience sampling with 103 healthy participants who completed the study, comprising 74 (71.8%) women and 29 (28.2%) men; 22 (21.4%) dropped out during the intervention, as they did not complete 80% of the proposed activities. The average age was 22.76 (SD 2.78) years and gender differences in the sample were due to the specific characteristics of the chosen degree, with a larger female representation. The participants were distributed into three groups via the use of the Telegram app (Telegram Messenger Inc): (1) the CG (n=24); (2) the experimental group with no additional social reinforcement (EG-nR; n=36); and (3) the experimental group with additional social reinforcement (EG-R; n=43). Participation in the study was voluntary and anonymous and required informed consent.

Ethics Approval, Informed Consent, and Participation

This study was approved by the Ethics Committee of the Universidad de Alcalá (reference: CEI/HU/2020/46). The research complied with all national regulations and followed the tenets of the Declaration of Helsinki. The data of the participants were treated confidentially, and no personal information was accessed. Privacy was respected, and no personal information has been published. All the participants provided informed consent.

Instruments

An ad hoc self-administered questionnaire about facial self-touches and the game #RedPingüiNO was administered to the participants using an easy survey platform before and after the intervention (the items in the instrument are listed in Multimedia Appendix 1). The instrument was made up of 43 items that were divided into 5 blocks and prepared from the following theoretical framework: (1) sociological issues (1-5), (2) hygiene habits (6-13), (3) risk awareness (14-19), (4) strategies for not touching the face (20-26), and (5) questions after the intervention (27-42). The fifth block was designed as a postintervention questionnaire and was administered only to the participants of the experimental groups (EGs). The items were closed ended, except for 1 open-ended question that collected considerations regarding the game (item 43).

The content validation of the questionnaire was conducted by expert judges [25]. A total of 12 judges (8 women and 4 men) assessed the content and form of the questionnaire. Their professional experience ranged from 11 to 35 years in scientific research related to the study, coming from various universities and heterogeneous fields of interest (body language, health, psychology, and didactics). The experts performed an overall assessment of the questionnaire and rated the degree of adequacy (relevance and wording). They were also asked about a set of aspects associated with the elaboration processes (appearance, clarity and length of the instructions, item format, and question order); data collection (completion time); and data interpretation (objectivity and absence of biases). The psychometric analysis of the content validity criteria of the instrument was performed using the V coefficient given by Aiken [26], considering the proportion of judges who express a positive assessment as a criterion for revising or eliminating items. An intervention pilot test and the registration were conducted by 4 teachers over a period of 5 days, during which they played the game and provided their assessments.

The participants of the EGs had to complete a daily self-compliance record of occurrence with 6 questions about the evolution of the intervention using the Microsoft Forms (Microsoft) tool and had to provide the following via Telegram: anonymous identification; frequency, prevention, and main reason for self-touches; motivation; and additional information. In the web space created for the EG-R, social reinforcement actions were carried out, freely sharing, among the participants, experiences during the intervention, daily achievements, difficulties, and additional information.

Procedures

This research was coordinated and developed by faculty members and research staff who specialized in body language, with at least 10 years of experience. The questionnaires were administered by evaluators who were unaware of which group the participants belonged to, and the participants were unaware of the existence of other intervention groups.

The participants continued their daily routines throughout the intervention without supplementation of any other activity. The intervention was carried out for 2 weeks (November 23, 2020, to December 7, 2020) during the school term to foster the existence of a normalized context and to avoid the effect of holiday periods on the variation of routines. During this period, an attempt was made to modify the behavior of facial self-touches of the participants of the 2 EGs, EG-nR and EG-R, compared with that of the participants of the CG through the use of serious play. The reminders, sent via Telegram, occurred at the beginning of the day and around lunch time. At the end of the afternoon, a link to the registry was sent. The social reinforcement in the EG-R was in the form of praise, support, and approval, with tangible rewards and individual and collective reinforcement. The communication strategies used included cooperation, participation, interaction, and comparison.

Data Analysis

Statistical analyses were performed using SPSS package (version 25.0; IBM Corp). The types of variables in the questionnaire, namely, categorical and dichotomous, made it necessary to use nonparametric tests. To study the reliability of the questionnaire, different statistics were used to assess test-retest reliability. To analyze whether there were statistically significant differences between the answers given to the same items in the test and retest, the Wilcoxon signed-rank test was used, except for dichotomous variables, which were analyzed using the McNemar index. In addition, the degree of correlation between the test and retest items was determined using the Spearman rank correlation coefficient for nonparametric samples. To demonstrate the reliability of items 27 to 42, which were answered only by the participants of the EGs, the Cronbach α was used. Furthermore, to analyze the significant differences between the different groups, the following was used: for groups taken 2 by 2, the Mann-Whitney *U* test for 2 independent samples and (2) to compare the 3 groups, the Kruskal-Wallis test for 3 independent samples. Finally, content analysis was used to analyze the open-ended questions in the questionnaire [27].

Results

Reliability and Validity of the Instrument

The V coefficient by Aiken [26], which was used to determine validity, was interpreted using the score method [28], and it showed a very positive and adequate result for the use of the questionnaire. This procedure was developed based on the expert method, assuming a 95% CI (*P*=.05). The value of the test was V=0.99 for the adequacy of the items and V=0.96 for the wording, with minimum values of 0.88 and 0.87, respectively. Table 1 shows the reliability of the instrument for items 6 to 26. The test-retest values were adequate because they were .05; therefore, it was not necessary to remove any of the items. The Spearman rank test for nonparametric samples confirmed these results, because no correlations .05 were observed.

Items 12 and 13 of the yes or no responses regarding the frequency of facial self-touches with a mask and knowledge of the facial T-zone did not show statistically significant differences (*P*=.45 and *P*=.53, respectively). The participants of the CG showed a higher frequency of facial self-touches with a mask (13/24, 54%), and 75% (18/24) knew about the facial T-zone before filling out the questionnaire. The reliability of the instrument for items 27 to 42 related to the intervention was analyzed using the Cronbach α (.723). The Cronbach α coefficient showed a value .70, which is the usual acceptance limit [29]. In summary, the questionnaire was valid, reliable, and therefore suitable for use.

Table 1. Reliability analysis of the questionnaire for the control group (n=24).

Hygiene Habits, Risk Awareness, and Strategies to Avoid Touching the Face

The significant pre- and postintervention differences in the participants of the EGs in terms of hygiene habits, risk awareness, and strategies to avoid touching the face are shown in Table 2. As Table 1 shows that there are no statistically significant differences in the CG, this information is omitted from Table 2.

Hygiene habits showed significant differences ($P<.05$) at pre- and postintervention time points in several items, as shown in Table 2. The 2 EGs showed coincident positive significant differences in item 9, which is related to the disinfection of objects. Item 6, regarding the frequency of handwashing, establishes a significant positive difference in the EG-R and a negative difference in the EG-nR. In addition, the participants of the EG-nR improved the behavior of avoiding touching the facial T-zone (item 7). Items 12 (EG-R, $P>.99$; EG-nR, $P=.73$) and 13 (EG-nR; $P>.99$) did not show significant differences at pre- and postintervention time points, with the exception of the EG-R for item 13, knowledge of the facial T-zone ($P=.01$). The participants of the EGs showed a higher frequency of facial self-touches with a mask (45/79, 57%), and 77% (61/79) knew about the facial T-zone before filling out the questionnaire. Risk awareness establishes pre- and postintervention differences (EG-nR and EG-R) in item 19, showing a perception toward greater ease in avoiding the behavior of touching the face. Moreover, the EG-nR showed higher values in the perception of the risk of touching the face (item 15).

By contrast, regarding the strategies for not touching the face, as the main objective of this study, consistent significant differences were observed. In the pre- and postintervention analysis, both EGs showed a reduction in the perception and frequency of facial self-touches (items 20 and 26). However, the EG-R established a positive significant difference in the perception of the magnitude of this behavior (item 26); this result is possibly related to an increase in perceptive capacity. In addition, a clear improvement was observed in the perception of the possibility of reducing facial self-touches with training and the importance of awareness of the behavior among the participants of EG-nR (items 22 and 23) and in seeking a simple solution to avoid a risk behavior among the participants of EG-R (item 24). The significant differences between the groups are shown in Table 3.

Regarding hygiene habits, there were differences between the CG and the 2 EGs, and the comparison of the 3 groups in relation to the ability of avoiding touching the facial T-zone favored the EGs (item 7).

With respect to risk awareness, positive significant differences were only observed between the CG and EG-nR, the CG and EG, and among the 3 groups in 2 items, 15 and 16, related to touching the face and handwashing. Finally, regarding the strategies for not touching the face, differences were observed between the CG and the 2 EGs, with higher rates observed in the EGs. These differences were observed for items 20, 24, and 25 in the EG-nR; for all items except 21 in the EG-nR; and for all except 21 and 23 in the full EG. In addition, differences were observed among the 3 groups for items 20 and 24. No significant differences were observed between the 2 EGs in any section.

Table 2. Significant differences between pre- and postintervention measures in the experimental groups.

#RedPingüiNO Intervention

The intervention showed that 94% (74/79; EG-nR: 34/36, 94% and EG-R: 40/43, 93%) of the participants in both EGs achieved greater awareness of the times they touched their faces (item 27), and 95% (75/79; EG-nR: 34/36, 94% and EG-R: 41/43, 95%) of the participants perceived that they had managed to reduce the number of facial self-touches (item 28). There were no significant differences between both groups (*P*=.51 and *P*=.86, respectively). The intervention improved the awareness of the reasons why the participants touched their face in each situation (item 42), with a rate of 3.53 (SD 0.60) (mean 3.47, SD 0.56, for the EG-nR and mean 3.58, SD 0.63, for EG-R) on a 4-point Likert scale (1=totally disagree and 4=totally agree). Table 4 shows the results of the strategies, materials, and evaluation of the #RedPingüiNO intervention.

Table 4. Significant differences between experimental groups (EGs).

Item	EG, mean (SD)	EG-nR[a], mean (SD)	EG-R[b], mean (SD)	Mann-Whitney *U* test score for EG-nR and EG-R (*P* value)
29	3.13 (1.15)	3.33 (1.07)	2.95 (1.19)	.09

[a]EG-nR: EG with no additional social reinforcement.

[b]EG-R: EG with additional social reinforcement.

[c]Statistically significant differences (*P*<.05).

Strategies and Materials

On a 4-point Likert scale, where 1 was “Little” and 4 was “A lot,” the intervention groups showed high rates in the perception of the different materials, highlighting recording (31) and video (item 36) over infographics (item 32). The strategies in the game of saying “No!” (item 29) and saying “Bravo!” (item 30) had high and similar results in both the groups. The follow-up strategy (item 33) was assessed by the participants of the EG-R at a higher rate than those of the EG-nR, without it being significant (*P*=.07). The Telegram strategies with high rates in both groups also did not establish significant differences between the 2 EGs (items 34 and 35).

Evaluation of the Intervention

The intervention was assessed by the participants of the 2 EGs as engaging (item 37), helpful (item 38), and motivating (item 39), with high rates; however, the EG-R showed a higher rate than the EG-nR in the perception of the appeal of the intervention (*P*=.045). In both groups, the duration was perceived as sufficient, with high means (item 40) and a higher rate in the EG-R than in the EG-nR (*P*=.001). In addition, the serious game proposed as an intervention strategy was perceived as suitable for use within the school context (item 41), with high rates in both groups. Therefore, although the results are satisfactory in both groups, social reinforcement seems to have an impact on the perception of the intervention with higher means in the EG-R in all cases, regardless of whether they establish significant differences. This highlights the perception of the intervention as an engaging way to train awareness to not touch the face long enough to achieve changes in this behavior.

Development of the Daily Intervention Log

In the analysis of the development of the daily log, a significant positive difference is observed in relation to the times that the participants of both EGs consciously stopped their hand before touching their face with a “Bravo!” (EG, *P*<.001; EG-nR, *P*=.01; and EG-R, *P*<.001), as well as a significant negative difference in relation to the frequency in which the facial T-zone was touched, and they realized it with a “No!” (EG, *P*<.001; EG-nR, *P*=.049; and EG-R, *P*<.001), possibly due to the significant reduction in facial self-touches. These data must be understood as the perception of a decrease in the frequency of facial self-touches. The reasons for facial self-touches were not modified among participants throughout the intervention. The participants of the EG-nR and EG-R established the reasons for touching their face as itching, lacrimation, and tingling (EG-nR: 17/36, 47%, preintervention and 16/36, 44%, postintervention; EG-R: 26/43, 61%, preintervention and 21/43, 49%, postintervention); restlessness, discomfort, and boredom (EG-nR: 13/36, 36%, preintervention and 12/36, 33%, postintervention; EG-R: 10/43, 23%, preintervention and 9/43, 21%, postintervention); and learned gestures (EG-nR: 6/36, 17%, preintervention and 8/36, 22%, postintervention; EG-R: 7/43, 16%, preintervention and 13/43, 30%, postintervention). The motivation perceived by the participants throughout the intervention showed a significant improvement, on a 5-point Likert scale, in the EG-nR (3.47, SD 0.87 at preintervention and 4.06, SD 1.09 at postintervention) and in the full EG (3.59, SD 1.25 at preintervention and 3.93, SD 1.16 at postintervention). This difference is not established in the EG-R (3.65, SD 1.40 at preintervention and 3.86, SD 1.21 at postintervention), owing to the perceived high motivation at the start of the intervention.

Discussion

Principal Findings

The main objective of the #RedPingüiNO intervention was to reduce facial self-touches as a preventive measure against SARS-CoV-2 and other pathogens in various health contexts. The newly constructed tools developed for analyzing the intervention established adequate validity and reliability. After the 2-week intervention, the participants perceived improvement in their hygiene habits strategies, such as handwashing; disinfection of objects; the use of a handkerchief; and the action of avoiding touching the eyes, nose, and mouth. After the intervention, the perception of the risk that facial self-touches entail increased within the EGs, but at the same time, touching the face was noticed as an easier behavior to avoid. The participants in the 2 EGs perceived that they had reduced the number of facial self-touches following the intervention. Participants' perception of the specific number of times they touched their faces also increased. They became more aware of the reasons why they touched their faces on a daily basis, the frequency of this behavior, and the importance of this awareness for self-regulation and avoiding self-touches. #RedPingüiNO was considered an appropriate and fun experience. More than half of the people who participated rated the game with qualifiers like "satisfactory," "rewarding," "positive," "fun," "useful," or "surprising"; moreover, during the intervention, motivation increased as they perceived the achievement.

Comparison With Prior Work

This study seems to reinforce that changes in health behaviors are possible with appropriate tools. This need is based on the idea that the most effective steps to reduce infection and death rates during the pandemic have been based on changes in individual behavior [2]. After the intervention, touching the face was noticed as an easier behavior to avoid, which coincides with the approach of Heinicke et al [30]. These authors indicate that reducing or stopping facial touching is a habitual and prevalent behavior that is unlikely to decrease unless we train with specific strategies for self-regulation, which implies awareness and the establishment of effective responses. Facial self-touches seem to increase in frequency and duration in emotionally or cognitively challenging social situations. This may be due to the attention states, working memory processes, and emotion-regulating functions [12] associated with such situations, which are developed and maintained based on the body language used in interactions with oneself and other people. Itching, lacrimation, and tingling were the most noted triggers of this behavior among the participants who subsequently experienced restlessness, discomfort, and boredom; the participants were somewhat less alert to the learned gestures.

The increased perception of a reduction in the number of facial self-touches seems to respond to the fact that during serious play, there was an improvement in awareness of this behavior that involved limited cognitive effort, control, and intention [31]. This can be seen in the progressive increase of "No!" in the log and how the positive reinforcement also increased with the passage of time when stopping self-touches with the "Bravo!" strategy. These game dynamics respond to the need for control over self-touches, which must be trained through habits to block, divert, or perceive the act through attention and anticipation, as well as from the reflexive capacity of movement [2]. Although we perceive the touch when it has already occurred, with repetition, there is a possibility of anticipating and paying the necessary attention to stop the action before it happens.

Although the effectiveness of strategies using mindfulness [32] or using technological means, such as software [33], camera and sensor networks [34], and smartwatches [35], to reduce facial self-touches is being investigated, specific strategies should be provided to reduce self-touches, ranging from awareness to easily understanding triggers and mechanisms to regulate one's own behavior, if possible, from everyday contexts [8,9,15,36]. This was the case in this intervention. One participant said as follows:

> *The most important thing in this experience is to consider each situation that causes me to touch my face or the situations that do not. I have questioned every detail (makeup, fringe, daily face washing, piercings, glasses, hot-cold, allergies, etc.)* [participant 14]

Thus, awareness is understood as a mental activity of the individuals that enables them to feel, have a reflexive knowledge of their actions, and know about themselves in particular, including actions less regulated by consciousness.

This serious game was considered useful, satisfactory, and fun—an intrinsic aspect of the act of playing [37]. This shows the positive balance of game design by providing a state of well-being, pleasure, and enjoyment, as described in flow theory [38], reinforcing the notion that serious games can be a playful and effective methodological framework for learning [39,40]. In a game aimed at learning, the media and materials are fundamental and enable its development [41], and if they are technological, they can be relevant allies for interaction [42], as the highly valued video tutorials, infographics, daily logs, and the Telegram group proved to be in this study. In summary, a game like #RedPingüiNO is based on its design and implementation, and therein lies its potential, taking care of the aspects of the mechanics, dynamics, and aesthetics framework. This mechanics, dynamics, and aesthetics framework is a formal approach to understanding games, which attempts to bring together game design and development, criticism, and technical research [43].

Starting from these elements, the intrinsic motivation of the participants was sought from Marczewski theory [44], valuing autonomy in game development, the mastery that enabled the participants to be aware of the progress they were achieving, the purpose for which they were playing, and their relationships. Regarding the latter, the participants from the groups both with and without reinforcement managed to be more aware of the times they touched their faces and perceived a reduction in self-touches. However, the participants in the EG-R considered the game more appealing, believed more firmly that the allotted time was sufficient, and presented higher frequencies of self-touch awareness and restraint during the recording. In summary, the game without this accompaniment was helpful, although the collective support and reinforcements promoted among those who played it may have a relevant supporting role. Regarding playing with other people, a significant number of participants indicated that they had shared it with their families and friends, seeking out that social reinforcement themselves but within their own environment:

> *[W]hat has struck me the most in this intervention has been the fact that I shared it with my family. They have helped me to be much more aware of the number of times I touch my face.* [participant 8]

> *I have learned a lot, in fact, I have encouraged my family and friends to do it with me and together we have greatly reduced how much we touch our faces. When we sat down to eat, we talked about it and we kept a family ranking too.* [participant 17]

Limitations and Future Directions

#RedPingüiNO resulted in a significant and helpful serious game that increased the perception of face self-touch avoidance. However, this study had some limitations. First, the sample used was a small number of university students, and it would be expedient to conduct future research with larger and more diverse samples. Second, owing to the specific characteristics of the university groups of students, there was a certain difference between the number of male and female participants in the different groups, and the CG had a smaller number of participants, which could bias the results. However, no significant gender differences were found in the study. Third, data on whether participants touched their face were not obtained from recordings. As not touching the face is a self-controlled behavior, these data were collected via a questionnaire and the daily logs of participants, and the results could be overestimated or underestimated. Therefore, as this behavior was not directly observed, these results must be understood as participants' perceptions of the decrease in the frequency of facial self-touches.

However, these limitations may present an opportunity because self-control itself has been one more strategy for reducing facial self-touches, with people taking a more active role in being aware of it and playing the game in their daily environments, not under laboratory conditions or in simulations. The perception of automated behaviors serves as a mechanism for self-control, which is facilitated by the awareness generated through conscious observation. Moreover, the perceived efficacy of the game invites to demonstrate its potential among other populations, such as health care workers and susceptible people, or within other environments.

Conclusions

This study provides evidence on the possible impact of the serious game #RedPingüiNO in reducing the behavior and perception of touching the face and its mucous membranes and may have an effect on the prevention of infectious diseases in different health contexts, such as those caused by SARS-CoV-2 and other pathogens. Being able to exert some control over this transmission path from within a game has allowed for better conscious control beyond verbally warning people not to touch their faces. The implemented tools were considered valid and reliable. Participants perceived a reduction in facial self-touches after the intervention and became more aware of their risk behaviors. The play strategy of #RedPingüiNO is simple and motivating in its format, precisely because it deals with a complex behavior that has a high degree of unconscious movement and automatic action, which is regulated by various contextual internal and external communication situations for the individual. Challenge-oriented mechanics, levels, and humor-based onomatopoeia reinforcement, as well as accessible and free gameplay components, make this serious game adaptable to other contexts such as health institutions, hospitals, community centers, schools, or similar entities. We also noted that the game could have a greater effect if it is shared, and the experience is reinforced by the interactions between the participants. #RedPingüiNO can help control risk behaviors against infectious diseases or in exceptional health situations. In summary, this study can be presented as a precedent for the self-control of behaviors related to health at different levels.

Acknowledgments

The authors wish to thank the Universidad de Alcalá for its collaboration and action during the COVID-19 pandemic. This project obtained a recognition diploma from the Universidad de Alcalá, a distinction for its contribution to alleviating the situation caused by the COVID-19 pandemic. The authors also wish to thank all the people and experts who collaborated in the development and dissemination of the project. This work was supported by the research project COVID-19 UAH 2019/00003/016/001/019, funded by the Universidad de Alcalá and Santander Universidades.

Authors' Contributions

MAB designed and directed the study. MAB, PSO, and AVS performed the bibliographic review. MAB, PSO, AVS, and IAI structured the theoretical bases and developed the project. AVS organized the development of the instruments. MAB, PSO, and AVS performed the interventions. CJL developed the statistical analysis and structured the results. MAB, PSO, AVS, CJL, and IAI wrote the manuscript. MAB, AVS, and IAI reviewed the draft manuscript. MAB, PSO, AVS, CJL, and IAI approved the latest version of the manuscript.

Abstract

Background: Eating disorders and obesity are serious health problems with poor treatment outcomes and high relapse rates despite well-established treatments. Several studies have suggested that virtual reality technology could enhance the current treatment outcomes and could be used as an adjunctive tool in their treatment.

Objective: This study aims to investigate the differences between eating virtual and real-life meals and test the hypothesis that eating a virtual meal can reduce hunger among healthy women.

Methods: The study included 20 healthy women and used a randomized crossover design. The participants were asked to eat 1 introduction meal, 2 real meals, and 2 virtual meals, all containing real or virtual meatballs and potatoes. The real meals were eaten on a plate that had been placed on a scale that communicated with analytical software on a computer. The virtual meals were eaten in a room where participants were seated on a real chair in front of a real table and fitted with the virtual reality equipment. The eating behavior for both the real and virtual meals was filmed. Hunger was measured before and after the meals using questionnaires.

Results: There was a significant difference in hunger from baseline to after the real meal (mean difference=61.8, P<.001) but no significant change in hunger from before to after the virtual meal (mean difference=6.9, P=.10). There was no significant difference in food intake between the virtual and real meals (mean difference=36.8, P=.07). Meal duration was significantly shorter in the virtual meal (mean difference=–5.4, P<.001), which led to a higher eating rate (mean difference=82.9, P<.001). Some participants took bites and chewed during the virtual meal, but the number of bites and chews was lower than in the real meal. The meal duration was reduced from the first virtual meal to the second virtual meal, but no significant difference was observed between the 2 real meals.

Conclusions: Eating a virtual meal does not appear to significantly reduce hunger in healthy individuals. Also, this methodology does not significantly result in eating behaviors identical to real-life conditions but does evoke chewing and bite behavior in certain individuals.

KEYWORDS

exposure therapy; eating behavior; anorexia nervosa; bulimia nervosa; binge eating disorder; overweight; obesity; immersive virtual reality; VR; virtual reality

Introduction

Eating disorders and obesity constitute severe health problems in Western society. Globally, the prevalence of eating disorders has increased recently by 25% [1], and for obesity, it is estimated that, by 2030, 20% of the world's adult population will be obese [2]. Both health conditions considerably impair physical health, disrupt psychosocial functioning [1,3], and are risk factors for depression and anxiety disorders [3,4]. Both are expensive disorders, with the overall cost of eating disorders in the United States in 2018 estimated at $64.7 billion per year [5] and of high BMI worldwide in 2017 estimated to be $802 billion [6].

Although both health problems are related to food consumption, their commonalities are seldom discussed. For instance, the same eating behavior parameters (ie, eating rate and food intake) have been identified to increase the risk of developing anorexia and obesity [7,8]. A majority of these individuals have lost the ability to experience satiety during and after meals [7]. A key characteristic of anorexia nervosa is a slow eating rate, which stems from an effort to prevent weight gain by restricting food intake [7]. People with bulimia nervosa try to restrict their food intake to control their body weight but eventually become sufficiently hungry that they consume large amounts of food rapidly before purging [9]. Binge eaters have the bulimia intake pattern without purging [9]. Those who become obese often try to restrict their food intake, but their efforts are typically transitory and ineffective. Finally, a high eating rate is associated with increased food intake [8], excess body weight [8,10], and a larger bite size [8,11].

Eating disorders and obesity constitute severe health problems, and although their prevalence has increased over the years, there is still no consensus for their treatment [1]. The effectiveness of conventional eating disorder treatments, such as family-based therapy, psychopharmacological treatment, and cognitive behavior therapy, are weak [7], with most studies reporting poor long-term treatment outcomes [12]. Conventional treatment for obesity includes lifestyle modification (diet and exercise), medication, and bariatric surgery. The weight loss associated with lifestyle modification and medication interventions is also limited, due to poor adherence rates [13], and although bariatric surgery is the most effective weight loss treatment, it is associated with multiple health complications [14].

High relapse rates are reported for both eating disorders and obesity, with only some people with anorexia nervosa reaching full recovery [15] and people with obesity often regaining most of the lost weight [16]. Last, high dropout rates are another issue that affects the treatment outcomes. For instance, it is estimated that, for people with anorexia nervosa, the dropout rates range from 20.2% to 49.6% [17] and, for people with obesity, from 10% to more than 80%, depending on the treatment program [18]. Therefore, there is an urgent need to explore effective alternative treatments to address these health problems.

Virtual reality devices have been used in many areas of health care for a variety of applications from professional health care education to disease treatment [19]. Examples of conditions that have been treated successfully with virtual reality are anxiety disorders, phobias, stress management, posttraumatic stress disorder, acute and chronic pain management, autism, and physical rehabilitation [20,21]. An especially promising area of use may be for the assessment and treatment of eating disorders and obesity, for which virtual reality devices can be used as an adjunctive treatment tool [20,22,23].

Recent technological advancements have significantly decreased the cost of virtual reality, making the technology more accessible for medical treatments [24]. The ability to customize and control the virtual reality environment makes the application of this technology easier in a treatment context, since triggering certain fears may be difficult to reproduce in real life [25]. The scripted nature of a virtual reality app prevents the occurrence of unexpected situations and provides patients with a safe environment where they can experience specific aspects of life, allowing them to be "emotionally present" within the virtual environment [26]. Immersive virtual reality provides an even more intense experience for the user, using a virtual reality headset or multiprojected environments to generate realistic images, sounds, and other sensations [25].

Virtual reality exposure therapy has been successful in modifying body image distortions in people with obesity, binge eating disorder, and eating disorders not otherwise specified, leading to a reduction in inappropriate behaviors related to food and social relationships [27].

Besides modifying body image distortions, virtual reality studies of eating disorders have focused on exposure to virtual food stimuli [23]. Some of these studies aimed to assess emotional reactions or craving while using virtual reality, while others had therapeutic objectives [23]. The results suggest that the participants perceived the virtual reality environment as real and that it was able to elicit emotional responses (eg, anxiety, food-related thoughts) [23]. More specifically, for binge eating disorder and bulimia nervosa, studies indicate the potential utility of virtual reality in improving motivation for change, self-esteem, and reducing binge eating and purging behaviors [20].

In obesity, besides modifying body image distortion, virtual reality studies were successful at improving self-control, mood, and weight loss [28-30]. Another area of focus was to increase physical activity using "exergaming" as a potential treatment for obesity and diabetes. Exergaming's fundamental concept is to use vigorous body activity as the input for interacting with digital game content, in the hopes of replacing the sedentary activity that is typical of traditional keyboard, game pad, and joystick inputs [31,32].

In addition to these findings, a study that investigated the perceived usability of a virtual reality app that promoted normal eating behavior suggested that clinicians have a positive attitude toward using virtual reality when treating people with an eating disorder [33]. Considering the advantages provided by this technology, virtual reality could be a useful tool to address eating disorders and obesity via exposure therapy and behavioral training.

Although interest in using virtual reality for treating eating disorders and obesity has increased over the last 2 decades, there is a lack of studies examining the effect of behavioral training via virtual reality on eating behaviors and satiety [22,23]. It has been proven that better treatment outcomes are obtained when the treatment normalizes eating behavior [34]. Similar methods may be successful in treating other eating behavior problems. Thus, a behavioral training approach via virtual reality could provide a new adjunctive tool to the existing treatment of eating disorders and obesity.

Both the method (eg, virtual reality and immersive virtual reality) [23] and aim (eg, normalizing body image and food exposure) [22,23] of virtual reality studies in eating disorders and obesity have been inconclusive, and further work is required to clarify these findings. Another reason to investigate the effectiveness of virtual reality further is that clinicians have expressed concerns that people with anorexia nervosa could substitute virtual meals for real meals to reduce feelings of hunger without ingesting any food [33].

Therefore, the main aim of the study was to determine whether eating in an immersive virtual reality environment reduces hunger among healthy adults. The secondary aim was to describe any eating behavior differences between the consumption of virtual reality meals and real-life meals.

Methods

Participants

General inclusion criteria were women, 18 years to 28 years of age, a BMI from 18.5 kg/m^2 to 29 kg/m^2, not pregnant nor breastfeeding, and normal physical activity (<1500 metabolic equivalent of task min/week of moderate-to-vigorous physical activity level from the International Physical Activity Questionnaire). Health inclusion criteria were nonsmokers, the absence of temporomandibular disorders or recent serious dental surgery, not undergoing treatments known to affect appetite (eg, some psychotropic drugs, acetazolamide), and no previous history of eating disorders. Only nonvegetarians with no aversion to the food that was to be served were allowed to participate in the study.

Recruitment

Recruitment of participants started in October 2020 and ended in April 2022. Participants were recruited via digital meeting platforms, by contacting potential participants in person, and by hanging flyers around the university campus.

Instruments

BMI

To measure BMI, weight was measured using a body composition analyzer (Tanita BC-418), and height was measured using a stadiometer (Seca 216 1814009). To collect data on eating behavior (ie, chews, bites, forkfuls) a home security camera (Mi 360°, Xiaomi) was used. To display and interact with the virtual meal, we used a virtual reality headset (HTC VIVE Pro), which consists of a head-mounted device and accompanying handheld controllers. The headset provides 110 degrees of viewing at a resolution of 1440 x 1600 pixels per eye (2880 x 1600 pixels combined) and a refresh rate of 90 Hz.

Food Intake

To measure food intake throughout the real meal, a digital food scale (Mandometer version 4) was used. The Mandometer is a medical device that consists of a scale that is connected to a computer; the scale measures the weight of the food on the plate at a sampling frequency of 1 Hz [35]. Before starting a meal, a plate was placed on the food scale, and the weight of the plate was subtracted from the meal. Food was then served on the plate, and the weight of the food was registered throughout the meal.

Subjective Data

Subjective data were collected via a tablet (Samsung Galaxy Tab A7) using an in-house developed app containing all questionnaires to ensure that participants fulfilled inclusion criteria, and it also contained 1 questionnaire to collect outcome data.

Inclusion Questionnaires

The short form of the International Physical Activity Questionnaire was used to evaluate participants' physical activity and to exclude those with too high moderate-to-vigorous physical activity levels [36]. The questionnaire consists of 7 questions, for example "During the last 7 days, on how many days did you do vigorous physical activities like heavy lifting, digging, aerobics, or fast bicycling?" The Health questionnaire was used to exclude individuals who were not healthy enough to participate or did not fulfill the inclusion criteria. The questionnaire consists of 25 questions about the general health of the participants (eg, "Do you often have infections like cough or sore throat?"). The Dutch Eating Behavior Questionnaire was used to assess 3 distinct eating behaviors (external, emotional, and restrained eating) [37]. The questionnaire consists of 33 questions, such as "If you have put on weight, do you eat less than you usually do?", "Do you have the desire to eat, when you are emotionally upset?", or "If you see others eating, do you also have the desire to eat?"

Outcome Questionnaire

Subjective appetite, mood, and taste of the food were rated using a meal questionnaire, which consists of 25 questions divided into 2 parts. The first part, "before meal," consists of 6 questions about mood (eg, "Are you feeling tense right now?") and 6 questions about appetite (eg, "How hungry do you feel?"). Mood and appetite questions were rated on 100-mm visual analog scales ranging from 0 to 100, with the verbal anchors "Not at all"=0 on the left side and "Extremely"=100 on the right side. The second part, "after meal," consists of 6 questions about appetite (same as before the meal) and 7 questions about the taste of the food (eg, "How fatty did the food taste?") on visual analog scales identical to that presented before the meal.

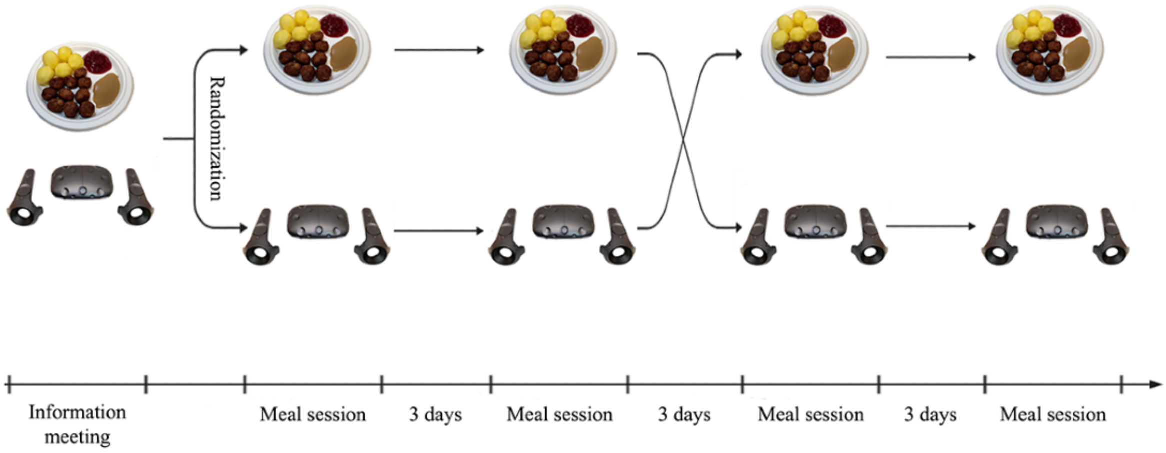
Ethical Approval

The research protocol was approved by the Swedish Ethical Review Authority (D.nr: 2019-04249).

Procedure

The study consisted of 5 meetings in a randomized crossover design, in which participants acted as their own control with 2 conditions, each with 2 repeats. Respondents first attended an information meeting where they ate an introduction meal. During the remaining 4 meetings, participants were either served a virtual or a real meal in a randomized order (Figure 1). All 5 meetings, including the information meeting, were held on weekdays (Monday to Friday) during lunch hours (11 AM to 1 PM) and had a wash-out period of at least 3 days. Both the real-life and virtual reality meals were recorded using a video camera.

Figure 1. Study design.



The day before each meeting, participants received an email with information regarding the type of meal (virtual or real) that they would have. To control for satiety, participants were reminded to eat the same breakfast the day of the meeting, at least 3 hours before, and to refrain from high-intensity physical activity 24 hours before the meeting. All the real meals were prepared by the researchers in the clinic 30 minutes to 60 minutes before the participants' arrival. All the prepared meals were kept in the oven at a temperature of 80 °C to ensure proper serving temperature. In the virtual world, the size of utensils, food containers, and food items were equivalent to the matching real-world item. Size-to-weight of food items in the virtual world was calculated, and corresponding meatballs and potatoes were purchased for the real-world meals, resulting in meatballs weighing 14 g each and potatoes weighing 60 g each.

Information Meeting

During the information meeting, respondents were provided with detailed information about the study, data collection, handling and secrecy, and the potential risks associated with participating. Besides informing them, the purpose was to ensure their eligibility to participate in the study, familiarize them with the study procedures, and provide a baseline food intake value for the rest of the meals. Each participant signed a written consent form and proceeded to answer the Health and the International Physical Activity Questionnaires. Once the questionnaires were reviewed and approved, the participant's height and body composition were measured.

Afterward, the introduction meal was served. In total, 1.2 kg of food was served, consisting of meatballs (400 g) and boiled potatoes (800 g). Brown sauce and lingonberry jam were placed in separate ceramic bowls on the table with a glass of water (200 mL). After the food had been served, the participant filled in the "before meal" part of the meal questionnaire. Once completed, the participant was instructed to put food on the plate that had been placed on the food scale and to eat the meal as they normally would, with no time nor intake restriction (ad libitum). Finally, instructions were given for the participant that they could add food to the plate or leave food on the plate and to refrain from using a mobile phone or other distracting elements while eating. Once the participant was finished putting food on the plate, the food scale and the video camera were turned on. After meal termination, the participant filled in the "after meal" part of the meal questionnaire.

The next step of the procedure was the virtual meal, for which the participant was taken to the virtual reality room, seated on a real chair in front of a real table, and fitted with the virtual reality equipment. The virtual reality room showed a kitchen that included a table, chair, and windows that revealed a natural scene. In the virtual reality environment, the controllers were represented by hands. The introduction meal consisted of several steps, teaching the participant how to serve themselves and consume food in the virtual reality environment [33]. A virtual tablet presented what tasks to perform to proceed to the next step. Each step ended by pressing the "next" button. In every step, a new "object" appeared on the table starting with a plate and continuing with meatballs in a pan, potatoes in a pot, brown sauce in a sauceboat, lingonberry jam, a jug of water, a glass, and cutlery [33]. After completing all previous steps, the participant could freely "cut" and "eat" the food.

Real-life Meal

The meeting for the real-life meals started by measuring the participant's body composition and filling in the "before meal" part of the meal questionnaire. The participant was then led to the room where they would eat. The room was designed to be as neutral as possible, with only a table and a chair (Figure 2). The meal was served on a plate that was placed on the food scale, with a glass of water alongside. The quantity of food on the plate was the same as the amount of food that the participant consumed during the introduction meal, plus an extra 50% portion on the side (Figure 3). The same instructions as in the introduction meal were provided. Once the participant was done eating, they filled in the “after meal” part of the meal questionnaire.

Figure 2. Research room.

Figure 3. Food was served, and 50% of the portion was placed on the side.

Virtual Meal

The meeting started by measuring the participant’s body composition. Afterward, the participant was taken to the virtual reality room (Figure 4), filled in the “before meal” part of the meal questionnaire, and was fitted with the virtual reality equipment. The meal served in virtual reality was the “same” as the real meal; the portion of the virtual meal was equivalent to the portion that was consumed during the introduction meal. There was extra food in the containers placed on the table, enabling free addition of food to the plate (Figure 5). Once the participant was ready to eat the virtual meal, the video camera and the acquisition software from the computer were initiated by the researcher. The purpose was for the meal to be eaten normally with no time restriction. Once the participant was done, the “after meal” part of the meal questionnaire was filled in.

Figure 4. Virtual reality room.

Figure 5. Virtual reality environment.

Data Formatting

Video recordings from both virtual and real meals were annotated using The Observer XT 16 (Noldus). The eating-related behaviors annotated were forkful, food addition, bite, and chew. Forkful was annotated as a point event when the fork touched the plate to pick up food. Addition was annotated as a state event, starting when food was added to the plate and ending when no more food was added and food ingestion started again. Bite was annotated as a point event when the mouth was closed around the fork. The virtual food did not require bites, as the food was "eaten" by putting it close to the headset. Chew was annotated as a point event when teeth occlusion and activation of masseter and temporalis muscles occurred.

Statistical Analysis

Statistical analyses were carried out using R software version 4.2.1 [38]. Since participants conducted 2 meals for each eating condition (2 real and 2 virtual meals), the average of every measured outcome (eg, food intake, hunger) was calculated. Thus, for each eating condition, 1 value (the mean) was created and was used in the analysis. For example, the food intake of the virtual reality meal refers to the mean food intake from the first and the second virtual reality meals.

The Shapiro-Wilk test and visual inspection of a Q-Q plot were performed to ensure normal distribution of the data. For the parameters that were not normally distributed, a Wilcoxon signed rank test and a paired Student *t* test were performed. Since the interpretation (ie, rejection or nonrejection of the null hypothesis) to both tests were identical for all investigated parameters, only *t* tests are presented in the results. The relevant parameters tested were hunger before and after the virtual and real meals, food intake, meal duration, eating rate, forkfuls, and additions, between the real and virtual meals. A subgroup was created from the participants who took chews and bites in the virtual meals. Additional *t* tests were performed for this subgroup, comparing chews and bites in the virtual meal to the real meal. Last, the same test was performed for all participants to evaluate the effect on hunger and meal duration between the first and second meals in both eating conditions. Pearson product-moment correlation was used to examine the association between hunger after the meal and meal duration and chews, as well as the correlation between meal duration and chews and food intake. Caution is required when interpreting all correlation analyses including chews from the virtual reality condition as a parameter, since in more than one-half of the measurements, the number of chews was 0. A significance threshold of $P \leq .05$ for all statistical tests was used. Unless otherwise specified, values are expressed as mean (SD). For the power calculation, a sample size of 20 was found to be sufficient for the study, using the effect size between real meal conditions of previous studies, an α cutoff of .05, and power of 0.80.

Results

Participants

Of 24 participants, 20 finished all parts of the study (Table 1); 2 participants dropped out due to scheduling difficulties, 1 participant was excluded due to corrupt data, and 1 participant was excluded due to suspected conformity bias, based on low food intake. No participant was excluded based on questionnaire responses.

Table 1. Demographic data of the participants (n=20).

Demographic characteristics	Results, mean (SD)
Age (years)	23.9 (2.5)
Weight (kg)	61.2 (9.6)
Height (cm)	165.3 (7.4)
BMI (kg/m^2)	22.4 (2.8)
Body fat (%)	27.5 (5.1)

Hunger Before and After Meals

For the virtual meal, participants rated their hunger before and after the meal at 66.9 and 59.9 (out of 100), respectively, resulting in no significant difference in hunger before and after the virtual meal (*P*=.10). For the real meal, participants rated their hunger before and after the meal at 68.6 and 6.9, respectively, resulting in a significant reduction in hunger after the real meal (mean difference=61.8, *P*<.001). One participant had a reduction in hunger similar in size to what was expected for a real meal as a result of eating a virtual meal, with a rated reduction of 59.

There was no significant difference in hunger before the meal between the virtual and real meals (*P*=.79), but hunger was significantly higher in the virtual condition after the meal (mean difference=–53.1, *P*<.001).

Eating Behavior Characteristics

There was no significant difference in “food” intake between the virtual and real meals (*P*=.07). Meal duration was significantly shorter with the virtual meal (mean difference=–5.4, *P*<.001), which led to a higher eating rate (mean difference=82.9, *P*<.001) for the virtual meal. When the chewing time (burst interval) was removed from the virtual and real meals, there was no significant difference in meal duration between the virtual and real meals (*P*=.06). The number of forkfuls and number of additions were significantly lower with the virtual meal than with the real meal (mean difference=–13.0, *P*<.001 and mean difference=–2.0, *P*=.005, respectively). The results are presented in Table 2.

Table 2. Eating behavior characteristics from the virtual and real meals (n=20).

Eating behavior	Virtual meal, mean (SD)	Real meal, mean (SD)	*P* value
Food intake (g)	375.6 (140.9)	338.9 (108.3)	.07
Meal duration (min)	3.6 (1.7)	9.0 (3.0)	<.001
Meal duration without chews (min)	2.8 (1.3)	2.4 (1.2)	.06
Eating rate (g/min)	124.0 (52.9)	41.1 (16.9)	<.001
Forkfuls (n)	25.9 (9.8)	38.9 (14.8)	.002
Additions (n)	0.6 (0.8)	2.5 (2.9)	.005
Bites (n)	10.0 (11.7)	40.0 (15.8)	<.001
Chews (n)	28.9 (68.0)	419.0 (162.9)	<.001

Chews and Bites

For participants who took bites and chews in the virtual meal, the numbers were significantly lower compared with the real meal (n=14, mean difference=–28.1, *P*<.001 and n=6, mean difference=–387.4, *P*=.004, respectively). The results are presented in Table 3.

Table 3. Mean values from participants who took bites (n=14) and chews (n=6) in the virtual meal.

Eating behavior	Responding (n=20), n (%)[a]	Virtual meal, mean (SD)	Real meal, mean (SD)	*P* value
Bites	14 (70)	15.4 (11.2)	42.4 (16.1)	<.001
Chews	6 (30)	82.4 (97.5)	469.8 (193.0)	<.001

[a]Number included in the analysis, based on the participants who took bites or chews in the virtual meal.

Familiarization Effects

There was a significant reduction in meal duration from the first virtual meal to the second virtual meal (mean difference=0.4, *P*=.03) but no significant change in meal duration between the first real meal and second real meal (*P*=.07). There was no significant difference in hunger before the meal between the first virtual meal and second virtual meal and between the first real meal and second real meal (*P*=.40 and *P*=.22, respectively).

Association Between Hunger and Chews and Meal Duration

In both the virtual and real meals, a low correlation was found between hunger after the meal and number of chews (r=–0.10, *P*=.68 and r=–0.18, *P*=.44, respectively). A low correlation was also found between hunger after the meal and meal duration in both the virtual and real meals (r=–0.12, *P*=.60 and r=–0.12, *P*=.62, respectively).

Association Between Meal Duration and Chews and Food Intake

In both the virtual and real meals, a low correlation was found between meal duration and food intake (r=0.22, *P*=.35 and r=0.14, *P*=.56, respectively). A high correlation was found between meal duration and chews in the virtual and real meals (r=0.69, *P*<.001 and r=0.75, *P*<.001, respectively).

Discussion

Principal Findings

To our knowledge, this is the first study to investigate the effect of a virtual meal on hunger and to explore the differences in eating behavior between real and virtual meals. The findings of this study indicate that eating a virtual meal does not affect hunger in healthy women. The results demonstrated that participants consumed approximately the same amount of real and virtual "food," but the virtual meal was significantly shorter, resulting in a higher eating rate. Participants also had lower numbers of chews, bites, forkfuls, and additions in the virtual meal.

Comparison With Prior Work

It is expected for hunger to decline throughout a real meal, which was the case for the real meal condition. Meanwhile, eating a virtual meal did not significantly reduce hunger. The nonsignificant difference in hunger before and after a virtual meal suggests that such meals can be used for people with anorexia nervosa without the risk of having them replacing real meals with virtual meals. This finding is in contrast with a study in which participants were found to decrease their consumption of a particular food (eg, cheese) by repeatedly imagining eating it [39]. Since this study was conducted with healthy women, care will be required when implementing this method for eating disorders or obesity.

The extent to which a virtual meal represents realistic eating conditions was also examined, although the aim of the virtual reality app was not to mimic real-life eating behavior. Interestingly, even though the meal duration of the virtual meal was shorter than that of the real meal, the amount of "food" consumed was approximately the same. The reason for this phenomenon was that most of the participants did not chew during the virtual meal, resulting in an approximately 3 times higher eating rate compared with the real meal. These data support previous research, which showed that eating rate was inversely related to the number of chews [40]. Changing the virtual reality protocol to elicit a more realistic eating behavior or providing virtual reality eating training may result in a satiety response. However, findings suggest that this approach would not be beneficial as an intervention for obesity or bulimia nervosa.

A serendipitous finding of the study was that, although it was not required nor requested, participants took bites and chews during the virtual meals, indicating that the virtual reality environment was perceived on some level as being real. The display of eating behaviors similar to real life is in line with the findings that cue exposure in virtual environments is effective for inducing food craving in healthy control participants [41].

The familiarization effect observed in the virtual meals suggests more meals are required to reach a stable behavior since several participants experienced difficulties. Examples of those difficulties were placing the food in their mouth and grabbing or serving the food on their plate. People are less accustomed to eating virtual meals than real meals, and that conclusion is also supported by a study that examined the impact of the environment on eating behavior using virtual reality [42].

Based on previous findings, we expected longer meals (ie, longer exposure to food "images") [43] and more chews (ie, more oral processing) [44] to be negatively associated with hunger. However, the correlation was low in both cases. These correlations should be interpreted with care, since they were not part of the initial hypothesis (we did not know participants would chew virtual food) and the fact that more than one-half of the participants did not chew in the virtual meal.

Strengths and Limitations

The main strength of this study was the use of immersive virtual reality equipment, as this technology increases the feeling of being present in the environment [20]. Other strengths were that many confounding covariates were controlled through the deployment of a random crossover design [45], narrow inclusion criteria, a strict study protocol [42], a familiarization meal, and objective data collection methods. For the introduction meal, a larger portion (1.2 kg of food) than what is typically ingested was offered to the participants to make them realize they did not have to consume everything. For the coming meals, they were provided with the same portion size as they ate during the introduction meal with extra food on the side. The artificial manipulation of portion size ensured similar meal sizes, making hunger, eating rate, and other eating behavior parameters comparable [46].

The main limitation of the study was the novelty of immersive virtual reality. Participants unused to immersive virtual reality require practice and concentration to understand the "game" mechanics [42]. It was observed that, in the introduction meal, several participants experienced difficulties handling the food (eg, placing the food in their mouth and grabbing or serving the food on their plate). Some participants expressed surprise or amusement during their encounter with virtual reality equipment (especially the first time), which may have influenced the results. Another limitation was that the virtual reality app required food on the plate and in containers to start, which resulted in alterations to the real meal protocol as well. Ideally, participants would have only received food on the plate for each session.

Other limitations include a lack of effect size measurements from previous virtual reality meals for the power analysis and potential low generalizability to people with eating disorders or obesity, because the study enrolled only healthy women. Moreover, the recruitment location (university campus) may have resulted in a convenience sample, in regard to education, socioeconomic status, technological literacy, and availability (workdays from 11 AM to 1 PM). In addition, the subjective methods used to quantify hunger are vulnerable to demand bias, in which the participants provide responses that they believe the researchers are looking for [43]. However, there are no reliable biological markers to evaluate appetite [47].

Future Perspectives

Further investigation is necessary to confirm the safety of virtual reality for patients, as they may respond differently than healthy control participants. Future studies should aim to include other demographic groups (eg, men, children, vegans, and other groups prone to eating disorders or obesity) to evaluate the generalizability of the findings. The effect of a virtual meal should also be investigated in different settings (eg, at home, at a restaurant, lunch with friends) and with a variety of foods. Moreover, future studies should provide additional virtual meals to reduce the familiarization effect observed in this study. Looking to the future, further attempts at incorporating chewing in the virtual meal (eg, with chewing gum to mimic food mastication) and using more advanced equipment that allows the involvement of all the senses (eg, sounds and olfactory information) might prove beneficial in evoking physiological responses similar to those of real meals.

Conclusions

This study investigated the effect of virtual reality on hunger. Eating in an immersive virtual reality environment has no significant effects on hunger in healthy individuals, suggesting that virtual reality can be used for patients (eg, with anorexia nervosa) without the risk of having them replace real meals with virtual meals. Due to the lack of chewing, the virtual meal was consumed in less time, while the food intake was approximately the same as in the real meal. Surprisingly, some participants took bites and chews in the virtual meal, although they were not instructed to nor was it required to "eat" the food.

Acknowledgments

The material and methods used and the collection of data used in this study were financially supported by the Mandometer clinic. The funding organization had no role in designing the study, collecting, and analyzing the data, or in preparing this manuscript.

Conflicts of Interest

PS and CB own shares in Mandometer AB, the company that financed the development of the virtual reality app. Other authors have no conflicts of interest to declare.

Abstract

Background: Several stand-alone smartphone apps have used serious games to provide an engaging approach to quitting smoking. So far, the uptake of these games has been modest, and the evidence base for their efficacy in promoting smoking cessation is still evolving. The feasibility of integrating a game into a popular smoking cessation app is unclear.

Objective: The aim of this paper was to describe the design and iterative development of the Inner Dragon game within Smoke Free, a smartphone app with proven efficacy, and the results of a single-arm feasibility trial as part of a broad program that seeks to assess the effectiveness of the gamified app for smoking cessation.

Methods: In phase 1, the study team undertook a multistep process to design and develop the game, including web-based focus group discussions with end users (n=15). In phase 2, a single-arm study of Smoke Free users who were trying to quit (n=30) was conducted to assess the feasibility and acceptability of the integrated game and to establish the feasibility of the planned procedures for a randomized pilot trial.

Results: Phase 1 led to the final design of Inner Dragon, informed by principles from psychology and behavioral economics and incorporating several game mechanics designed to increase user engagement and retention. Inner Dragon users maintain an evolving pet dragon that serves as a virtual avatar for the users' progress in quitting. The phase-2 study established the feasibility of the study methods. The mean number of app sessions completed per user was 13.8 (SD 13.1; median 8; range 1-46), with a mean duration per session of 5.8 (median 1.1; range 0-81.1) minutes. Overall, three-fourths (18/24, 75%) of the participants entered the Inner Dragon game at least once and had a mean of 2.4 (SD 2.4) sessions of game use. The use of Inner Dragon was positively associated with the total number of app sessions (correlation 0.57). The mean satisfaction score of participants who provided ratings (11/24, 46%) was 4.2 (SD 0.6) on a 5-point scale; however, satisfaction ratings for Inner Dragon were only completed by 13% (3/24) of the participants.

Conclusions: Findings supported further development and evaluation of Inner Dragon as a beneficial feature of Smoke Free. The next step of this study is to conduct a randomized pilot trial to determine whether the gamified version of the app increases user engagement over a standard version of the app.

smoking cessation; mobile app; games for health; gamification; software design; feasibility; mobile phone

Introduction

Background

Cigarette smoking is a leading preventable cause of death and disease in the United States [1]. Although many clinic-based and phone-based smoking cessation treatments are effective, most people who try to quit smoking do so without any aids and are successful <5% of the time [2]. The recommended cessation treatment, which combines counseling with medication, is used by <5% of those who attempt to quit [3].

Smartphone apps for smoking cessation have become increasingly popular among smokers who want to quit. As of 2020, English-language smoking cessation apps had been downloaded 33 million times [4]. The low cost and convenience of smartphone-delivered support makes them an appealing alternative to clinical treatments for many smokers, especially those disproportionately affected by the harms of smoking such as low-income, less educated, and racially minoritized subgroups [5]. In addition, the widespread availability of smartphones—85% of US adults owned one as of 2021—has helped extend the reach of smoking cessation apps to a large number of people [6]. Thus, smartphone-based interventions hold great promise for reducing the high burden and disparities in smoking-related cancer risk and mortality. Although many cessation apps do not follow evidence-based guidelines [7-9], a few are now being developed using established behavior change theory and existing clinical guidelines.

A perennial challenge for mobile health (mHealth) apps is their low engagement and retention rates [10]. Overall, <5% of users actively use a downloaded mHealth app daily, and <5% of users continue to use the app after 10 days [11]. Approximately half of the participants in studies of app-based mHealth interventions drop out, and studies of app-based smoking cessation interventions have found similarly high dropout rates [12-15]. Given the potential for smartphone apps to reach millions of smokers and reduce tobacco use, it is important to find ways to engage app users and increase retention and efficacy.

Behavioral researchers have suggested using serious games and gamification techniques to promote behavioral health [16-18]. Serious games are games with a primary purpose other than entertainment, such as health promotion. Gamification is a related motivation tool that uses nonmonetary rewards to make nongame activities fun or challenging. Gamification is designed to increase users' motivation and engagement, which in turn may increase exposure and adherence to a smoking cessation program [19]. A study found that approximately 75% of the adult smokers surveyed played video games [20], and many smokers believed that game-based interventions for smoking cessation would be motivating [20,21].

Several gamified apps have been developed to help people quit smoking, such as Cigbreak [22], Crush the Crave [23,24], Inspired [25], QuitIT [26,27], Quittr [28,29], and Tobbstop [30,31]. A small number of randomized controlled trials of these apps have been conducted, and they have generally found that users were satisfied with the gamified app, but most did not experience significant increases in smoking abstinence [23,27,29,31]. User engagement and retention of these apps also varied, with each study adopting a different approach to measurement (eg, number of game "episodes" completed or minutes played). Nonetheless, nonrandomized studies have suggested that elements of gamification, such as achievement badges, may increase users' self-efficacy and motivation or intention to quit [32,33]. Taken together, these findings demonstrate limited and conflicting information regarding the effectiveness of gamified apps for increasing smoking cessation relative to quitting without assistance, and additional efforts are needed to improve user engagement and retention.

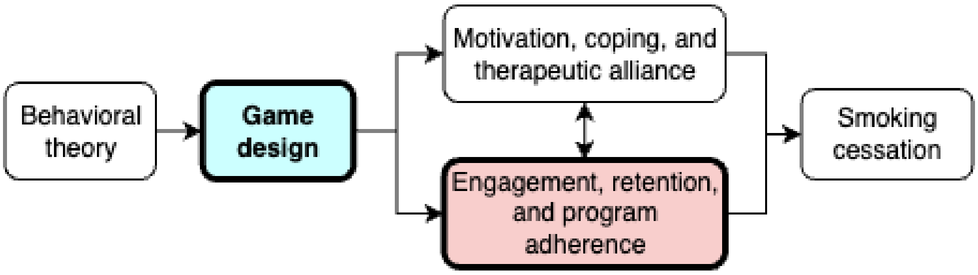
The Smoke Free App

Our team of academics and software developers sought to design and integrate a game into the Smoke Free smartphone app. Developed by London-based 23 Limited, Smoke Free is one of the most downloaded smoking cessation apps in the Apple and Android stores, with >800,000 downloads per year and 6 million downloads so far [34,35]. A preprint of a pragmatic randomized controlled trial reported that, although being randomized to receive an offer to use the Smoke Free app did not increase smoking abstinence compared with no intervention, the app increased continuous abstinence at 6 months when smokers who were randomized to receive the app downloaded it (12.7% intervention vs 7% comparator) [35]. The app leverages behavior change techniques that have proven to be effective in face-to-face behavioral support programs [36]. Key features of the app include (1) a calculator that tracks the total amount of money saved by not smoking; (2) a calendar that tracks the time elapsed since the user quit smoking; (3) a scoreboard that awards badges to users for not smoking; (4) progress indicators that inform users about health improvements that the user can expect because they started their quit attempt; (5) daily missions that assign evidence-based tasks to help users avoid and resist urges to smoke; (6) a diary and cravings log that track the frequency, strength, and location of cravings to smoke; and (7) a text-based chatbot that delivers quitting guidance in a friendly, conversational tone. In randomized trials, a full version of the app with chatbot was shown to increase user engagement compared with a reduced version of the app [37], and the daily missions were shown to increase user retention and self-reported smoking abstinence at 3 months [34]. The current standard version of the Smoke Free app does not contain gamification features apart from the virtual badges noted previously.

The Inner Dragon Game

Our team designed a theory-informed game called Inner Dragon and integrated it into the Smoke Free smartphone app. Inner Dragon uses game elements that incorporate behavioral insights to increase user engagement and retention. This increased engagement is expected to increase exposure and adherence to the smoking cessation program, which should improve the chances of quitting smoking (Figure 1). The process of developing Inner Dragon and the game design is described in the *Methods* section.

Figure 1. Conceptual model.



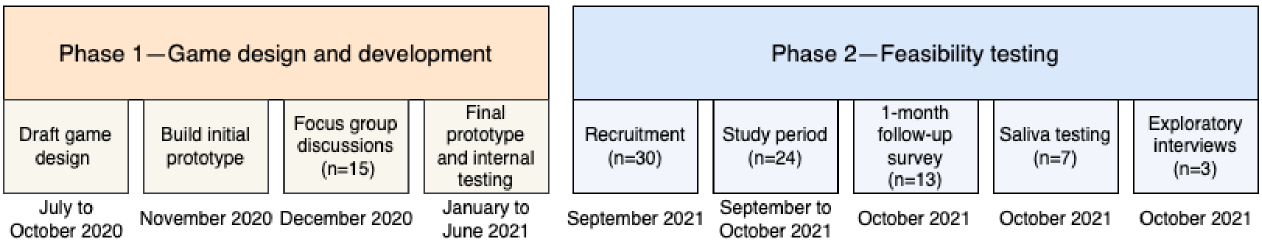
This feasibility trial is a precursor to a 2-arm pilot randomized controlled trial and part of a broad program that seeks to assess the effectiveness of gamifying an app for increasing smoking cessation. The pilot trial will evaluate the engagement, satisfaction, and early efficacy of gamifying the Smoke Free app compared with a standard version of Smoke Free to guide the design of a large trial. The aim of this study was to assess the feasibility and acceptability of adding the Inner Dragon gamification component to the existing Smoke Free smartphone app for smoking cessation.

Methods

Overview

The study was conducted in 2 phases. In the first phase, the study team designed and integrated the game into the Smoke Free app. In the second phase, the study team evaluated the feasibility and acceptability of the integrated game using a single-arm trial. An overview of the study approach is provided in Figure 2. Our approach follows the biphasic framework for gamification design by Marczewski [38], involving a first phase of planning and design based on iterative information collection and development and a second phase of measuring user activities and engagement [39].

Figure 2. Overview of study approach.



Phase 1—Game Design and Development

We followed a multistep usability testing procedure for the development of the Inner Dragon game: (1) we created a game design document and sketches of app screens for the game; (2) we conducted focus group discussions (FGDs) to gather feedback about sketches with Smoke Free users who are not participating in the feasibility trial; and (3) we finalized the game prototype, integrated it into Smoke Free, and performed internal app testing.

Game Development

As an initial step, we partnered with the game design studio, Workinman Interactive, LLC, to produce a game design document that described the significant features of the game. Workinman has a long history of developing games for apps and clients include Disney, Fisher-Price, and NBCUniversal. The investigative team provided an initial concept for the game. The game design document was refined based on a series of meetings and multiple rounds of revisions. Workinman also provided supporting art for wireframes, game flowcharts, and screen images. These materials were used by 23 Limited to build an initial prototype of the Inner Dragon game.

Design of Inner Design

In the Inner Dragon game, users care for a customizable pet dragon, whose growth reflects the user's own progress in quitting smoking. The game uses traditional virtual pet retention mechanics with some social features and many options for customization and personalization. Virtual pets have been popular with consumers because they can foster bonding and companionship [40]. The Inner Dragon concept is also broadly compatible with the genres of games most liked by adult smokers, namely action, role-playing, and action-adventure games [41].

Inner Dragon includes several game mechanics designed to increase user engagement and retention, with the primary goal of increasing exposure and adherence to the smoking cessation program, thereby improving the likelihood that the user quits smoking. Inner Dragon allows users to interact with a digital pet that is tied to their quit attempt as a means of progress toward continued abstinence, positive reinforcement for engagement with the smoking cessation program, and entertainment [40]. Game features were designed to accommodate any intensity of game play, whether heavy or sporadic, with no limitation on the amount of time or engagement. The key game mechanics were as follows. First, the user maintains a pet dragon that hatches on their quit day and evolves every 7 days to unlock new attributes and powers (Figure 3). The dragon acts as a virtual avatar that represents the user's progress. Second, the user earns experience points by engaging in selected in-app activities, including those in the game (eg, playing a minigame or feeding the dragon) and in the core Smoke Free app (eg, completing a mission or logging a diary entry). Rewards for engaging with core app features were designed to improve adherence to the smoking cessation program. The experience points unlock gifts and cosmetics, directly rewarding frequent and consistent use of the game. The user can customize their dragon (eg, wing shape or clothing accessories) over the course of the quit experience by steadily unlocking features. Third, the Inner Dragon home screen has "care meters" that users must work to keep from falling very low: calmness, nutrition, hygiene, and energy. Engaging with the dragon in various ways increases the meters. For example, petting the dragon increases calmness, and feeding the dragon increases nutrition. Caring for and interacting with a virtual pet through the care meters can foster a bond with the pet and motivate users to return to the game regularly [40]. Fourth, the game provides tools for the user to better cope with the challenges of withdrawal: a dragon-led breathing exercise to provide calmness and a memory minigame as a distraction. Fifth, a user can asynchronously interact with other users' dragons in a "dragon park" by (1) viewing their profile and progress and (2) sending and receiving motivational messages and emojis from a preset menu (Figure 4). These game mechanics are hypothesized to combine to increase the users' engagement with the app and, subsequently, their chance of quitting successfully.

The game design was informed by principles from the fields of psychology and behavioral economics. As noted in the following section, aspects of the game were motivated by several theories and theoretical constructs, such as self-determination theory, theory of present bias and hyperbolic discounting, theory of salience and limited attention, and variable reinforcement under operant conditioning. The avatar provides salient, visual feedback with endogenous value (tied closely to the user's motivation to quit) associated that may sustain and enhance motivation to quit. Self-determination theory predicts that this type of feedback is highly intrinsically motivating [42]. Furthermore, the user may identify with the digital pet as an avatar, and this may cultivate a digital therapeutic alliance with the game and app, for example, by creating a bond with the dragon and increasing the user's confidence to succeed [43,44]. The use of frequent, salient, in-game rewards was designed to counter the behavioral economic constructs of present bias and inattention to app use. The design further included evidence-based practices from contingency management, such as the use of escalating in-game rewards for abstinence, with a reset point for lapses and sustained abstinence (by harnessing regret and loss aversion) [45]. The use of surprise gifts provided a variable reward structure designed to boost engagement and novelty. The asynchronous interactions with other users in the dragon park provide opportunities for limited social support and social comparisons that may motivate the user to exert more effort in the quit attempt [46,47].

The various game mechanics and elements were designed to appeal to users with different motivations. For example, Yee [48] identified 3 main components of player motivation: *achievement* (advancement and competition), *social* (socializing and relationship), and *immersion* (discovery, customization, and escapism). The experience point system may appeal to achievers; the interaction with other players and a sense of connection with the dragon may appeal to socializers, and the rich opportunities for dragon customization and distraction game may appeal to players seeking immersion.

Figure 4. Dragon care. (A) Feeding dragon (fun). (B) Memory mini-game (distraction). (C) Breathing exercise (manage cravings). (D) Dragon park (social feedback and support).

FGD Procedures

Following the development of an initial game prototype, the investigative team conducted FGDs with existing users of the Smoke Free app to gather their feedback about the Inner Dragon game concept. The findings from the FGDs were used to refine Inner Dragon in preparation for the feasibility trial.

FGD participants were recruited using a recruitment message displayed to new Smoke Free users on an onboarding screen. The message included a hyperlink to a Qualtrics screening questionnaire. Eligibility criteria included the following: aged ≥18 years; had downloaded and opened the Smoke Free app; lived in the United States; spoke, wrote, and read English; smoked at least 1 cigarette every day; and was available during one of the scheduled FGDs.

The study team organized three 90-minute FGDs via Zoom (Zoom Video Communications). During each session, a facilitator guided the participants through several discussion topics: past smoking experience, preferences for methods of quitting, and feedback about the game prototype (Multimedia Appendix 1). For the latter topic, a facilitator provided the FGD participants with a description of the different elements of the initial prototype and accompanying screenshots. Participants received a payment of US $40 as a choice of a gift card or cash card provided through the Tremendous digital payment platform.

FGD sessions were transcribed. Overall, 2 independent coders identified key themes from the transcripts. Coders then input their findings into a series of "feedback capture grids," which organized the likes, criticisms, questions, and ideas of users for each discussion topic. Each gamification feature was evaluated with respect to its interest, ease of use, motivational potential, and overall satisfaction.

Phase 2—Feasibility Testing

Overview

This study included a single-arm, unblinded evaluation of the feasibility and acceptability of the Smoke Free app with integrated Inner Dragon game, in preparation for a planned randomized pilot trial. All participants in the feasibility study were given free access to the Smoke Free app with the integrated Inner Dragon game. Participants' use of the app was passively monitored for 28 days, and follow-up assessments occurred after 1 month.

Recruitment and Participants

Study participants were recruited from the population of general users of the Smoke Free app. Focus group participants were not included. New users of Smoke Free were invited to participate in a feasibility trial to quit smoking through an on-screen recruitment message presented on the initial onboarding screens within the app. The message asked the following: "Interested in a research study to test the latest version of Smoke Free? If you qualify you could earn up to US $100 and get some paid features for free!" The message included a hyperlink to a screening questionnaire and consent form in the Qualtrics web-based survey platform. Recruitment remained open until the prespecified sample size of 30 participants was met.

Inclusion criteria were the following: aged ≥18 years; downloaded and opened the Smoke Free app; lived in the United States; spoke, wrote, and read English; smoked at least 1 cigarette every day; planned to quit smoking within the next 7 days; and was willing to self-administer a salivary cotinine test remotely. At the end of the screening questionnaire, eligible respondents were asked to consent electronically to participate in the study. Respondents' eligibility data were automatically transmitted to Smoke Free's servers to designate each person as included in or excluded from the study. Following the completion of the remaining onboarding process in Smoke Free, eligible, consenting users were automatically given immediate access to Inner Dragon and certain core (ie, nongame) features of the app. Core features included all of those described previously, including the chatbot and daily missions, which are typically paid features.

Procedures

During onboarding, each participant in the feasibility trial selected their own planned quit date within 7 days of enrollment. Participants were invited to use the Smoke Free app in whatever way they liked for 28 days after their planned quit date. Therefore, all participants had the same amount of time with the app following their initial quit date. Use was self-directed and did not require any specific amount of time.

We collected self-administered questionnaire data from participants via Qualtrics at baseline and weekly on days 7, 14, 21, and 28 after the participant's planned quit date. After completing the screening questionnaire, meeting the inclusion criteria, and completing the informed consent in a web-based form, participants were automatically sent an email link to the baseline questionnaire. The 28-day ("1-month") follow-up assessment was the primary end point. Participants were sent 3 SMS text messages (1 invitation and 2 reminders) and 1 email reminder for the 1-month follow-up survey, using multiple modalities to try to increase response rates.

All participants who completed the 1-month questionnaire, regardless of smoking status, were invited to complete a salivary cotinine test to biochemically verify their smoking status. Within 2 business days of completing the 1-month follow-up questionnaire, participants were mailed a salivary cotinine test kit and test instructions by 2-day priority mail. We sent an email to participants with a link to a Qualtrics survey in which they were asked to upload a photo of the test results within 7 days of receiving the test kit.

Following the end of the saliva testing period, a randomly selected subset of participants was invited to participate in an exploratory 45-minute semistructured interview via Zoom to share their experiences with using the Smoke Free app.

Participants were eligible for up to US $95 in compensation. They received US $10 for completing the baseline questionnaire within 48 hours; US $5 for completing the weekly surveys on days 7, 14, and 21 within 48 hours; US $30 for completing the 28-day survey within 48 hours of being invited (or US $20 for completing it within 7 days); and US $40 for uploading a photo of their saliva test result within 48 hours of receiving the test kit (or US $30 for uploading a photo within 7 days). All study payments were delivered via email at the end of the study through Tango Card [49], a web-based gift card system that allowed participants to choose from a menu of Visa prepaid cards and hundreds of gift cards.

Outcomes

The study's outcome measures were selected principally to establish the feasibility and acceptability of the intervention and data collection methods for a planned pilot trial. The study had two primary outcome measures, both focused on user engagement: (1) the total number of unique app sessions from enrollment through 28 days after the user's initial quit date, measured as the number of times the app was opened, and (2) the mean duration of app sessions, in minutes, through day 28 after the quit date. Both outcomes were passively collected by the app. A new session was defined as opening the app after at least 30 minutes of inactivity.

Secondary outcomes focused on the feasibility and acceptability of the gamified app in the domains of (1) user engagement and retention and (2) user satisfaction. Secondary outcomes were the number of unique days with ≥1 app session; proportion entering Inner Dragon; and satisfaction with Smoke Free ("I liked using the Smoke Free app") and Inner Dragon ("I liked the dragon game"), reported on a 5-point Likert scale ranging from "Not at all" (score=1) to "Extremely" (score=5).

Tertiary outcomes included the following: (1) the proportion of participants who reported abstaining during the past 7 days at the 1-month follow-up assessment (self-reported 7-day point-prevalence abstinence); (2) biochemically verified 7-day point-prevalence abstinence at the 1-month follow-up assessment, obtained from uploaded results for a self-administered salivary cotinine test (Alere iScreen Oral Fluid Device); (3) program adherence, measured as the number of times of using selected core app features (reported a craving, recorded a diary entry, completed a mission, read a tip, and used the chatbot); (4) number of times of using selected game features (breathing exercise, cleaning the dragon, feeding the dragon, memory minigame, using the customization menu to change appearance, and reading the dragon instruction guide); (5) motivation to quit at the 1-month follow-up, reported on a 10-point scale ranging from not at all motivated (score=0) to very motivated (score=10); and (6) digital therapeutic alliance, measured from the bonding and confidence subscales of the Mobile Agnew Relationship Measure, reported on a 4-point measure and dichotomized at a threshold of "Agree" or higher [43,44].

Data Analysis

We started by calculating the descriptive statistics of demographic and smoking factors. For the primary aim, descriptive statistics were used to estimate user engagement with the app. A complete case analysis was conducted, including only those who opened the app after completing the screening questionnaire.

To explore the association between the total number of app sessions and the number of sessions with game use, we estimated an unadjusted linear regression of the relationship between the total number of app sessions and the number of sessions with game use. The total number of app sessions is equivalent to the total number of sessions with use of core features, because each session starts on the main dashboard screen that includes certain core features (eg, calculator of money saved by not smoking).

Smoking abstinence was assessed using both complete case analysis and assuming that nonrespondents were still smoking (ie, "missing = smoking"). Imputation methods were not used because of the small sample size.

As this was a feasibility study, the target sample size of 30 participants was based on budget and feasible accrual during the study timeline, rather than on a power analysis. Quantitative analyses were performed using Stata (versions 16.1 and 17.0; Stata Corporation).

Exploratory Qualitative Interviews

To assess the opinions about and use of the Smoke Free app with Inner Dragon, we invited the feasibility study participants to participate in a 45-minute semistructured interview via Zoom. The exploratory interviews occurred following the saliva testing period. Interview respondents received a US $50 gift card of their choice. The interview included topics about overall app experience, Inner Dragon game experience, and study and data collection processes (Multimedia Appendix 2). The qualitative interview data were compiled and summarized into key points.

Ethics Approval

The institutional review board of the University of California, San Francisco, approved study procedures for phase 1 and phase 2 (19-29335).

Results

Game Design and Development

In total, 3 FGDs were conducted via Zoom with 15 participants, each with 3 to 7 participants, between December 4, 2020, and December 11, 2020. Although participants had varied reactions to the prototyped concept, overall, the reaction was positive. Of the 15 FGD participants, 10 (67%) strongly agreed that they would like to use the gamified app frequently. Even when users expressed doubt or dislike, most (12/15, 80%) reported that the game, as presented, would likely encourage them to check the Smoke Free app more frequently, thus supporting the main study hypothesis.

FGD participants gave feedback about several aspects of the game. They tended to be the most enthusiastic about the "dragon park" and the ability to interact with other users and avatars. FGD participants wanted the game to hold them accountable, including by imposing a meaningful penalty for relapse. They preferred game features that facilitated distraction from and coping with cravings over pet care features, such as feeding the dragon, that were not directly connected to the quit attempt. FGD participants wanted the game to progress alongside the dragon's growth, for example, making leveling up more challenging as the game progresses. They tended to view the customization options as a means of distraction, rather than as motivation to continue engaging with Inner Dragon over time. Feedback from the FGDs and internal testing were incorporated into the final game design.

Feasibility Trial

Sample Characteristics

We screened 86 new Smoke Free app users over 3 days (September 8, 2021, to September 10, 2021) to reach our goal of enrolling 30 eligible, consenting participants for the feasibility trial (Figure 5). Of the 86 screened individuals, 56 (64%) were ineligible, of whom 9% (n=5) lived outside the United States, 11% (n=6) did not smoke daily, 93% (n=52) were not planning to quit within the next 7 days (including n=43, 77% who had quit already), and 14% (n=8) did not agree to complete a saliva test. Of the 30 enrolled participants, 24 (80%) opened Smoke Free after completing the screening questionnaire, thereby completing the onboarding process within Smoke Free. This is the denominator used for most of the analyses. There was 54% (13/24) response rate for the baseline questionnaire, 46% (11/24) response rate for the 1-month follow-up questionnaire, and 45% (5/11) response rate for the saliva test (only those completing the follow-up questionnaire were asked to complete the saliva test).

Table 1 shows the demographic and smoking-related characteristics of enrolled participants. Most (17/24, 71%) identified as female, and median age was 37 years. Most (21/24, 88%) were non-Hispanic White, and 8% (2/24) were non-Hispanic Black and 4% (1/24) was Hispanic. Among the 18 baseline survey respondents, median income was US $72,500, and there was a range of educational backgrounds, with 39% (5/13) having received a bachelor's or associate degree, 31% (4/13) having completed some college or technical school, and 15% (2/13) having received at most a high school diploma.

Participants who completed the baseline survey were asked questions about their smoking behavior (Table 1). Participants smoked a median of 15 cigarettes per day and had made a median of 5 past quit attempts. Participants had been smoking for a median of 18.5 years. Approximately 25% (3/12) of the participants reported using electronic nicotine delivery systems in the past 30 days, and 8% (1/12) reported using nicotine replacement therapy in the past 30 days. Most participants (18/24, 75%) set a quit date as within 1 day of enrollment.

Participants also reported about their past video game experience (Table 1). More than three-fourths (19/24, 79%) of the participants played video games at least monthly during the previous year, similar to the general population of smokers [20]. Moreover, 33% (8/24) of the participants played video games daily, and 33% (8/24) played at least weekly but not daily. Among participants who reported playing games monthly, mobile games were the most popular gaming platform (13/24, 54%), followed by web games (10/24, 42%).

[b]ENDS: electronic nicotine delivery system.

[c]NRT: nicotine replacement therapy.

User Engagement

User engagement with the gamified Smoke Free app was generally high: a mean of 13.8 (SD 13.1; median 8; range 1-46) app sessions per user and an average of 5.8 (SD 10.6; median 1.1; range 0-81.1) minutes per session (Table 2). Overall, 75% (18/24) of the participants entered the Inner Dragon game at least once. The number of sessions decreased rapidly during the first week after the participant's quit date, for sessions overall and those involving the use of Inner Dragon (Figure 6A). The decline in sessions with game use was similar to the decline in sessions overall, based on the change over time in the share of sessions with game use. The high variability in the total number of sessions by user is shown in Figure 6B. The use of the Inner Dragon game was positively associated with the total number of app sessions (correlation 0.57), such that each additional session with the use of Inner Dragon was associated with 3.1 (SE 0.96) more total sessions (*P*=.003; Figure 7A). In addition, the average time a user spent per session decreased with the total number of sessions for that user (correlation −0.39), such that each additional session was associated with 1.25 (SE 0.63) fewer minutes per session on average (*P*=.06; Figure 7B).

We further characterized the variability in the use of different features of the game. Figure 8 shows the use of various pet care activities in the game. Only 44% (8/18) of the participants who tried Inner Dragon used these pet care activities with some frequency.

Table 2. App use during the intervention.

	Participants, n (%)	Values, mean (SD)	Values, median (range)
App sessions (n=24)			
Sessions per user[a]	24 (100)	13.8 (13.1)	8 (1-46)
Minutes per session per user[a]	24 (100)	5.8 (10.6)	1.1 (0-81.1)

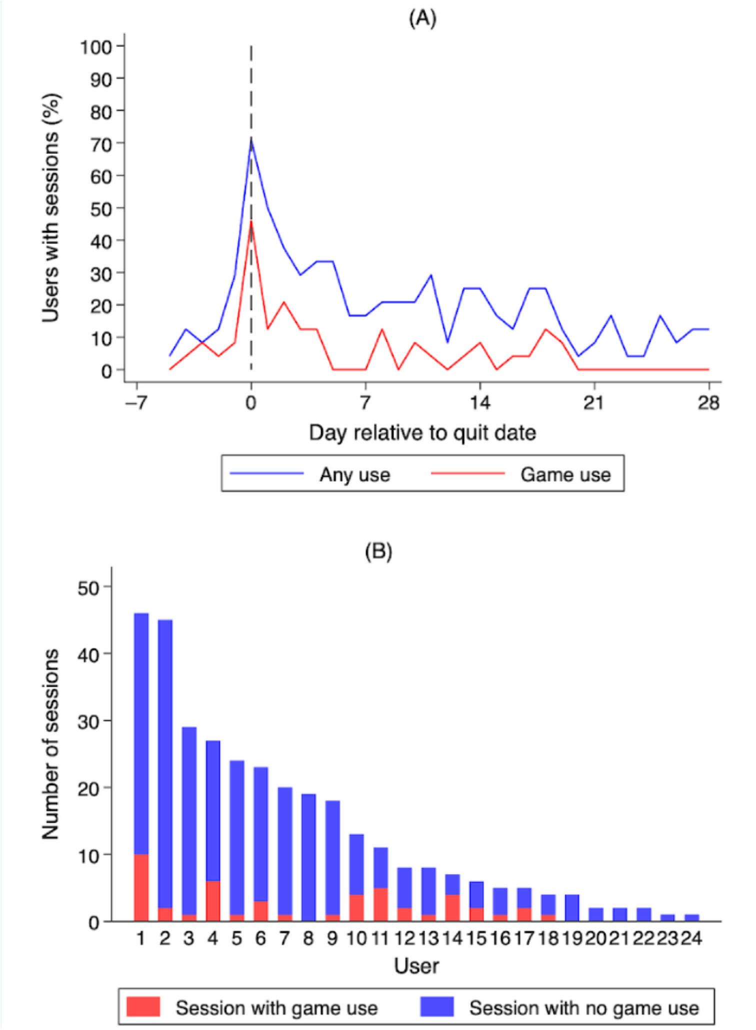

Figure 7. Association between number of sessions with and those without the use of Inner Dragon. (A) Number of sessions with game use. (B) Average minutes per session versus number of sessions.

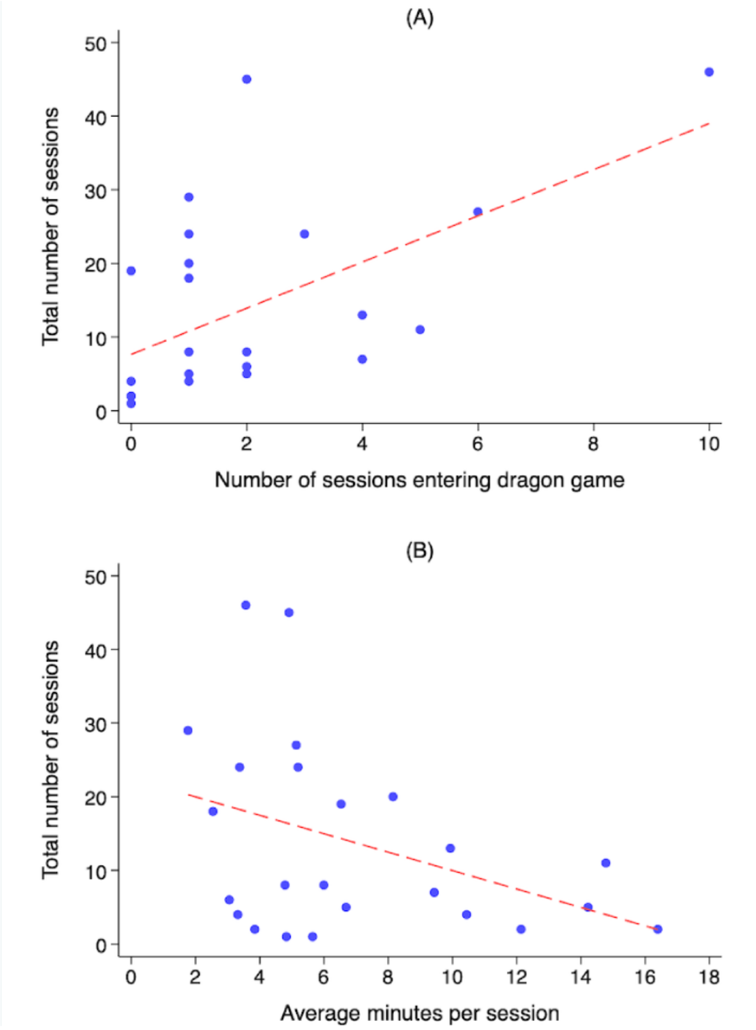

Figure 8. Pet care events by user.

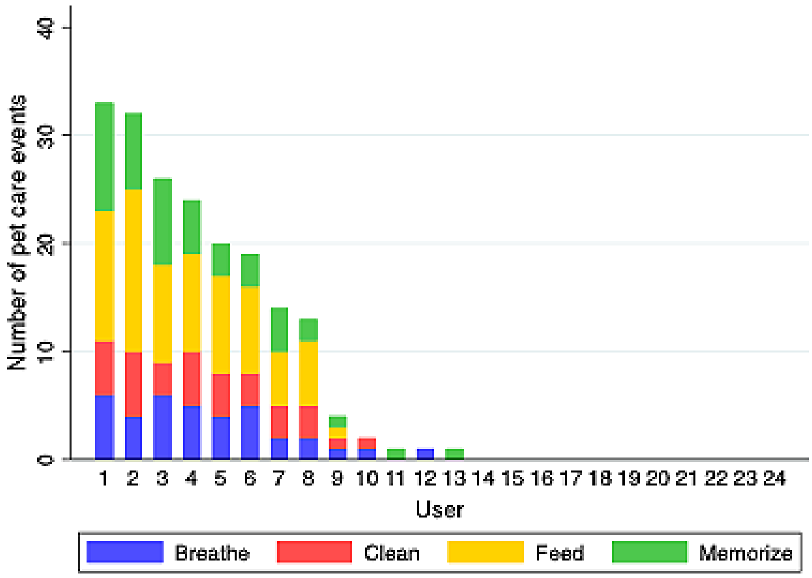

Efficacy of the Intervention

The percentage of self-reported 7-day point-prevalence abstinence at 1 month was 45% (5/11) among complete cases and 21% (5/24) when assuming that nonrespondents were still smoking. Biochemically verified 7-day point-prevalence abstinence was 27% (3/11) among complete cases who were mailed a saliva test kit and 13% (3/24) when assuming that nonrespondents were still smoking. Only 1 self-reported abstainer reported having used e-cigarettes in the past 30 days, but they did not complete the saliva test. None of the participants reported having used nicotine replacement therapy in the past 30 days.

The total number of sessions was positively associated with self-reported abstinence in a simple regression analysis. An additional session was associated with increase in abstinence of 1.3 percentage points when assuming that nonrespondents were still smoking (P=.04) and of 2.7% points with complete cases only (P=.01). However, the number of sessions with Inner Dragon use and the ratio of game sessions to total sessions were not associated with either measure of abstinence.

Satisfaction and Motivation

Among the 12 participants who completed the follow-up questionnaire, participants were very satisfied with the gamified Smoke Free app at the 1-month end point (mean score 4.1, SD 0.8 on a 5-point Likert scale). Satisfaction ratings were slightly higher among those who had used Inner Dragon (mean 4.2, SD 0.2; 9/12, 75%) compared with those who had not (mean 3.7, SD 0.3; 3/12, 25%); however, this difference was not statistically significant according to the Wilcoxon rank-sum test (P=.21). Only 25% (3/12) of the participants who had used Inner Dragon provided a satisfaction rating for Inner Dragon, because the question was not mandatory; their ratings were substantially lower (mean 2, SD 0.1) than that for Smoke Free overall.

Exploratory Qualitative Interviews

Qualitative interviews were conducted with 14% (3/22) of the participants who were invited and agreed to participate in the interview. Overall, 67% (2/3) of the interviewed participants had used the Inner Dragon game. In general, the participants liked the design of the app and had no major complaints. Participants found the progress indicators of health improvements as one of the most popular features, and 67% (2/3) of the participants commented about the helpfulness of the chatbot.

However, the participants reported that they had difficulty in understanding the purpose of the game and how to navigate the game. Participants also reported overlooking certain features of the game, such as the memory minigame. They recommended adding a notification to the dashboard that would link the users directly to the game and providing additional tutorials to explain the purpose of the game.

Adverse Events and Operational Issues

There were no adverse events reported during the trial. However, the study implementation faced technical challenges. In particular, we discovered that the dragon park had not been operational during the feasibility trial. Therefore, users were not able to use this key game feature, and user satisfaction may have been influenced accordingly. We had also planned to include a once-daily pop-up to assess daily smoking status; however, this also was not operational.

Discussion

Principal Findings

Drawing on multiple behavioral theories, we designed a unique, multifaceted digital pet game to promote user engagement and retention in a leading smartphone app for smoking cessation. Participants, who were given access to the gamified app, averaged 13.8 app sessions and 5.8 minutes per session throughout the 28-day trial. User satisfaction with the app was high; users reported an average score of 4.2 on a 5-point scale when asked if they "liked the Smoke Free app." Regarding smoking abstinence, 46% (5/11) of the participants reported having abstained from smoking during the previous 7 days, and 27% (3/11) of the participants were biochemically verified to have abstained.

The development process demonstrated the feasibility of integrating the Inner Dragon game within the Smoke Free app. The single-arm trial demonstrated the feasibility of performing planned procedures for a pilot randomized controlled trial and provided proof of concept that the Inner Dragon game might be able to increase the engagement of Smoke Free users. The evaluation found that user engagement with the gamified Smoke Free app was generally high, with considerable variability across participants. Short-term data about app use suggested that users who used the game more frequently were also more likely to use core app features more frequently. A randomized controlled trial could reveal whether this is a causal relationship. Participants in the feasibility evaluation liked the gamified app overall; however, we did not collect sufficient data to gauge their satisfaction with the Inner Dragon game.

Our study makes 2 key contributions to the literature about serious games and gamification for smoking cessation. First, although several existing games such as Tobbstop and Quittr use similar frameworks and game features to promote engagement and smoking cessation, our use of a digital pet is novel for smoking cessation apps. Second, we use the game in a unique context in which it is integrated into an app with 6 million downloads so far and available at a scale that is rarely achieved by serious games.

Comparison With Previous Studies

Our study of Inner Dragon contributes to the developing literature about the feasibility, engagement, and effectiveness of gamified smoking cessation apps. A small number of such apps have been developed and evaluated, including Crush the Crave [23,24], QuitIT [26,27], Quittr [28,29], and Tobbstop [30,31]. Overall, the literature highlights low user engagement for gamified smoking cessation apps. Crush the Crave participants reported an average rating of 2.4 out of 5 for their frequency of using the game [23]. QuitIT users also had low user engagement, with only 40% of participants reporting that they played the game [27]. User engagement was high among the Quittr users with access to the Tappy Town game (mean of 58.4 min of using the app over a 28-day trial) [29] and the Tobbstop app in which 65.9% of participants successfully used the app [31]. In comparison, 75% (18/24) of our study's participants used the Inner Dragon game in the Smoke Free app at least once throughout the 28-day trial, resulting in relatively high user engagement compared with other apps.

A small number of randomized trials have been conducted to evaluate the efficacy of gamified apps to improve smoking cessation. Although participants have generally reported high satisfaction with the gamified app, most of the apps have not demonstrated improved smoking abstinence rates [23,27,29,31]. Our feasibility trial found a point-prevalence abstinence that exceeded those reported for most other gamified smoking cessation apps (eg, 4% for Quittr, 14% for Crush the Crave, and 39% for Tobbstop); however, the gamified Smoke Free app will need to be tested in a randomized trial with a control group.

Future Directions

The feasibility evaluation produced several important findings with implications for the planned pilot randomized controlled trial and for future studies more generally. Several lessons relate to the game design. First, users reported overlooking the game entirely or not remembering to open it. To increase the visibility of the game, we subsequently included a message at the top of the main dashboard that linked to the game. A message linking to the game was also added under the *support* tab, where many other resources, such as the chatbot, were available. Second, to address participants' misunderstandings regarding the purpose of the game and the availability of game features, we created and embedded a promotional video that plays when the user opens the Inner Dragon screen for the first time. The video describes the purpose of the game and its relationship with the user's quit attempt and highlights the key features of the game, such as the breathing exercise. We also added and expanded on tutorials to clarify the availability and purpose of certain features. Third, we provided tight integration between Inner Dragon and the core features of Smoke Free through the use of more salient messaging outside the game and navigation buttons to the game. In particular, we added messages on nongame screens to inform participants when they earned experience points for completing core activities. For example, upon logging a diary entry, a message popped up to inform the user that they had won experience points that can be claimed in Inner Dragon, along with a button to navigate directly to Inner Dragon.

The feasibility trial also provided lessons for improving the study design of the planned pilot trial. The low response rates pointed toward a need to send reminder messages regarding questionnaires via SMS text message rather than via email. There was also a need to devise procedures for monitoring which app features were active.

Study Limitations

The study has important limitations. First, the small sample size limited the precision of estimates for main outcomes. Second, and relatedly, low response rates and the potential for selection bias made it difficult to assess certain outcomes, such as user satisfaction. However, our experience allowed us to formulate new procedures to improve participant retention. In response, we have planned a large pilot trial with 500 participants to mitigate this small sample size limitation. Finally, the follow-up period was short, and a long follow-up was implemented in the next phase of the project. Several game features, such as the dragon evolutions, converting experience points into gifts, and social interactions in the dragon park, provide the basis for promoting long-term engagement with the app, and this will require further design and development.

Conclusions

In summary, this trial showed that it is feasible to integrate a gamification component into an existing smartphone app for smoking cessation. Moreover, we developed a set of study procedures that could feasibly be used to evaluate the game intervention. Digital gamification is a promising strategy that merits further attention from smoking cessation researchers.

Acknowledgments

The authors would like to thank Keith McCullough and his team at Workinman Interactive, LLC, which contributed to the game design and provided artwork. Adam MacLean, Elena McGahey, Giselle Edwards, Pallavi Chaudhary, and Janardan Devkota provided valuable research assistance. Abstract

Background: Heart rate variability biofeedback (HRVB) is an established intervention for increasing heart rate variability (HRV) in the clinical context. Using this technique, participants become aware of their HRV through real-time feedback and can self-regulate it.

Objective: The aim of this study was 2-fold: first, to develop a serious game that applies the HRVB technique to teach participants to self-regulate HRV and, second, to test the app with participants in a pilot study.

Methods: An HRVB app called the FitLab Game was developed for this study. To play the game, users must move the main character up and down the screen, avoiding collisions with obstacles. The wavelength that users must follow to avoid these obstacles is based on the user's basal heart rate and changes in instantaneous heart rate. To test the FitLab Game, a total of 16 participants (mean age 23, SD 0.69 years) were divided into a control group (n=8) and an experimental group (n=8). A 2 × 2 factorial design was used in each session. Participants in the experimental condition were trained in breathing techniques.

Results: Changes in the frequency and time domain parameters of HRV and the game's performance features were evaluated. Significant changes in the average RR intervals and root mean square of differences between adjacent RR intervals (RMSSD) were found between the groups (*P*=.02 and *P*=.04, respectively). Regarding performance, both groups showed a tendency to increase the evaluated outcomes from baseline to the test condition.

Conclusions: The results may indicate that playing different levels leads to an improvement in the game's final score by repeated training. The tendency of changes in HRV may reflect a higher activation of the mental system of attention and control in the experimental group versus the control group. In this context, learning simple, voluntary strategies through a serious game can aid the improvement of self-control and arousal management. The FitLab Game appears to be a promising serious game owing to its ease of use, high engagement, and enjoyability provided by the instantaneous feedback.

Introduction

Background

Heart rate variability (HRV) represents the temporal variation between successive heartbeats (RR interval), and it is measured in milliseconds [1]. HRV is a biomarker of cardiovascular [2] and mental [3] health, reflecting the balance between the parasympathetic and sympathetic branches of the autonomic nervous system (ANS) [4]. HRV has been considered as an objective and noninvasive health indicator, with higher resting HRV being associated with lower cardiovascular risk [5], reduction of negative emotions through acute stress [6], flexible and adaptive response to environmental demands [7], and improved fitness [8]. This reflects the numerous applications of HRV in various fields.

HRV biofeedback (HRVB) is an established intervention that increases HRV in the clinical context and has proven to be effective as a treatment for anxiety and depression [9,10]. With this technique, participants become aware of their HRV through real-time feedback and can self-regulate it, restoring its homeostasis [11]. HRVB is based on the physiological phenomenon of respiratory sinus arrhythmia, which is defined as the variation in heart rate (HR) caused by respiration [12]. The analysis of respiratory sinus arrhythmia shows that the instantaneous HR (iHR) increases during inhalation and decreases during exhalation. Thus, the original HRVB procedure proposed by its promoters emphasizes the importance of breathing training to maximize HRV and achieve the maximum benefits of this technique [12]. In a recent systematic review [13], a series of methodological guidelines were proposed to improve the effectiveness of HRVB interventions. This review highlighted the importance of the breathing protocol as the core of the HRVB interventions, concluding that concrete aspects such as the inhalation, holding, or exhalation ratio should be explained in detail to the participants who apply the technique. Furthermore, HRVB can help establish a connection between the mind and body through voluntarily controlled physiological behaviors, such as breathing, facilitating the learning process and self-control.

HRVB is becoming more widely used owing to its ease of application and high cost-benefit potential, particularly because of the current accessibility of health technologies through mobile health devices [14,15]. The growth of mobile health technology has allowed the development of game-based mobile apps, which are known to increase the transfer of learning and motivation toward practice [16]. The use of games either in health or educational interventions allows the participants to immerse themselves in the activity that is required by the game, promoting a flow state [17,18]. Similarly, other studies have shown that when playing serious games, the student's role changes from a passive receiver of information to an active entity interacting with the game, facilitating the learning process [19,20]. Serious games, rather than being geared toward entertainment, are aimed at educating, training, and informing the player about a specific topic [21]. They are being used in various health domains [22-24]. For instance, in the field of HRVB, they can be a way to teach participants to control HRV through breathing techniques in an interactive environment.

Objectives

With the information provided in the *Background* section, the aim of this study was 2-fold: first, to develop a serious game that applies the HRVB technique to teach participants to self-regulate HRV and, second, to test the app with participants in a pilot study.

Methods

This study has two phases: (1) the development of a serious game biofeedback app called the FitLab Game and (2) the testing of the app with participants in a pilot study.

Phase 1: App Development

Visual Environment and Game Explanation

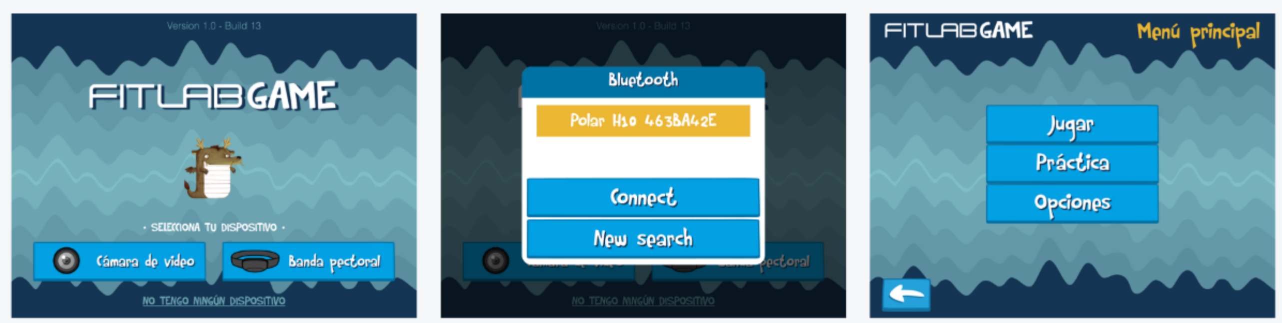
General Design

In accordance with definition of serious games by Djaouti et al [25], the FitLab Game is meant for physical and mental training in the health care sector and intended for the general public. The overall goal of the game is to help the user self-regulate their HRV by providing biofeedback in an attempt to follow or mimic a preset iHR waveform. The architecture and design of the game allows the incorporation of new real iHR curves (RR) to imitate and can be adapted to different levels of complexity in the different existing scenarios (levels). These real recordings can be chosen by the player or a professional accompanying the player. Depending on the level and the preset iHR waveform chosen, the game will lead to a state of relaxation (increasing cardiac variability) or a state of activation in the participant (decreasing cardiac variability), according to the needs demanded by each particular situation. Different gamification techniques were used in its design to increase the players' engagement with the tasks. More general techniques include having a goal to aim toward, a set of rules to follow, a challenge to complete, and *real-time* feedback to tell the player how he is doing and how close he is to completing the goal. More specific gamification techniques were added to further engage the player, including Bonus points, increasing challenge, and performance graphs.

Menus

The game's menus were designed in landscape mode and presented in Spanish. The first screen that appears when opening the app is the main screen, which allows users to choose the sensor used to input data: either the device's camera ("Cámara de vídeo") or a HR band ("Banda Pectoral"). The latter was used in this study. Once connected to the sensor, the app allows access to the game's mode, where the player can select between the option "Jugar" ("Play"), in which the user overcomes different levels in an orderly manner so that the difficulty of the game gradually increases, or the option "Práctica" ("Practice"), in which the user can activate an independent session. The tab "Opciones" ("Options") refers to the game's settings (Figure 1).

Figure 1. Screenshots of the game's menus. Game's transition from the main screen to the screen that appears when you select "Banda pectoral" ("Chest Band") and which allows to connect a heart rate sensor to the game. On the right, the third menu shows where the player can select "Jugar" ("Play") to play.



Screens

The FitLab Game has 9 levels distributed in 3 visually different worlds (Figure 2). Each world has 3 scenarios or levels of difficulty that the user must overcome in a set order to be able to access the next one when in "Jugar" ("Play") mode. To overcome a scenario, the user must move the main character up and down the screen to avoid colliding with obstacles that keep appearing. Touching an obstacle results in the loss of a life, and losing all lives means the game is over and needs to be restarted. The movement of the main character reflects cardiac variability and can be controlled by different voluntary strategies such as breathing.

The upper and lower limits and the obstacles in each scenario of the game are not placed randomly. They follow a specific waveform determined by previously recorded RR intervals, corresponding to a real recording. Each scenario represents a real RR series transformed and visualized as iHR, with different difficulty to imitate depending on the particular and distinct RR series (represented as a curve of iHR values) on which each scenario is based. Before starting the game, the data were calibrated to establish an initial HR range for the user (based on iHR from RR intervals). An algorithm was created specifically for the game, which takes this initial HR and displays it on a "grid" (invisible to the user) where each box is 1 second wide per 1 second high. With this algorithm, the screen is configured to place the character in the central area vertically, and the width of the screen is adjusted such that it is proportional to the range of variability presented by the user. In addition, the upper and lower limits and the obstacles, based on the previously recorded RR series, are placed above and below the defined waveform, leaving a space for the character to pass in between (Figure 3).

As a result of the initial calibration, all users start the game under similar conditions, while also having the level of difficulty of each scenario of the game adjusted to their own HR values. Overall, the configuration of each game is a dynamic and individual process, setting it apart from "one-size-fits-all" games. The individually tailored nature of the FitLab Game was designed to increase motivation and the learning process [26].

The left side of Figure 3 illustrates the algorithm that defines the ideal pathway of the character. The blue line represents the waveform defined by the prerecorded iHR curve (from a specific RR series), and the dark gray boxes represent the upper and lower limits of this curve, where the obstacles would be positioned. The right side of Figure 3 shows an example of how this algorithm would be seen in the game (see a dynamic example in Multimedia Appendix 1). Once the obstacles are placed, the objects and landscape of the scene are selected. For each world, there is a bank of images that can be used (mountains, animals, houses, etc) and placed by distributing them according to their size. Larger objects form the background plane, such as the mountains. Medium objects, such as houses, gradually fill the spaces that the first type of images could not fill because of their size, and small objects, such as birds, trees, or other details, are placed in the spaces that are missing to be filled in, which in Figure 3 are the dark gray boxes. Notably, the placement of obstacles is not exhaustive, meaning that it is not intended to fill all the space reserved for obstacles; otherwise, the screen will be saturated with objects. The goal is to place objects in the most harmonious way possible but clearly marking the path that the main character should follow. When the user reaches the end of the level or loses a life owing to touching obstacles, a final page appears. On this screen (Figure 4), a "Level Completed" message is shown, together with the total points collected, and the average stress index and average HR of the player and of all participants who have played the game is also shown.

Figure 2. Screenshots of worlds and scenarios of the game: "Campo" ("Rural area"), "Mar" ("Sea"), and "Espacio" ("Space").

Figure 3. Example of wave based on an instantaneous heart rate curve from a particular RR interval series.

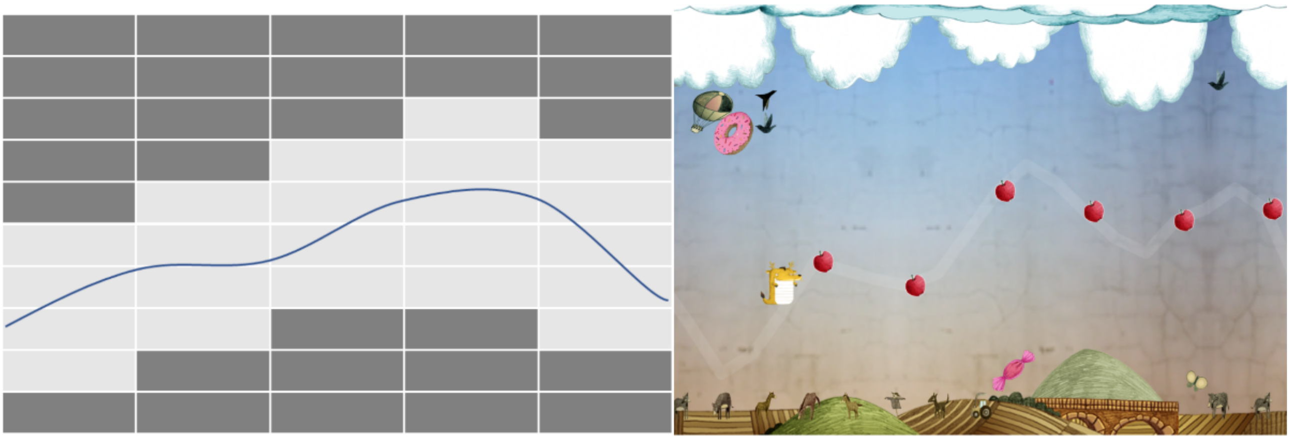


Figure 4. Example of the final page, appearing after a word of the FitLab Game is played.

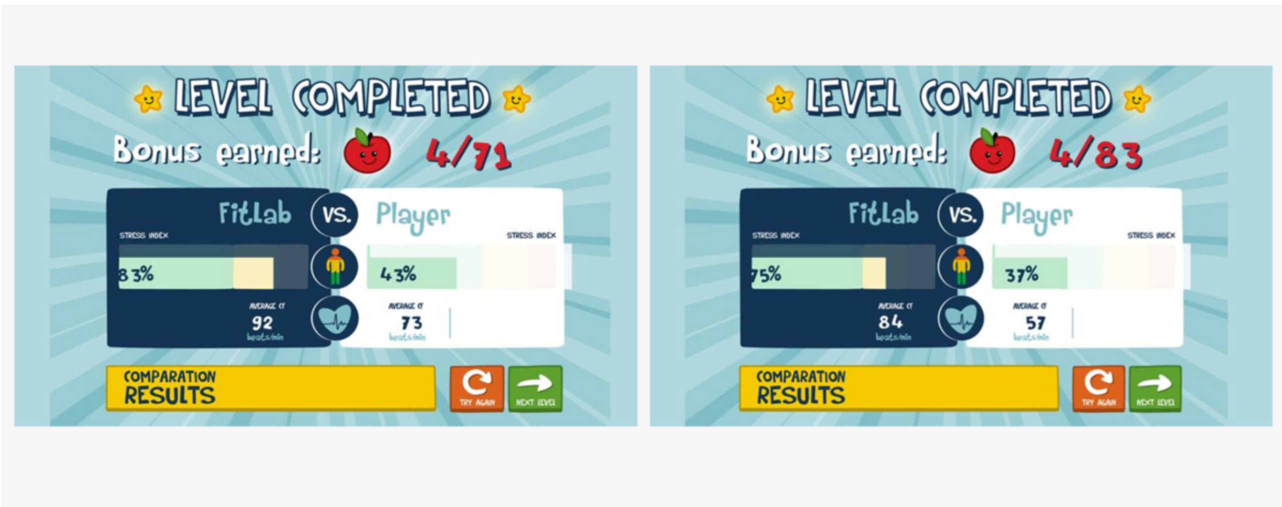


App Architecture

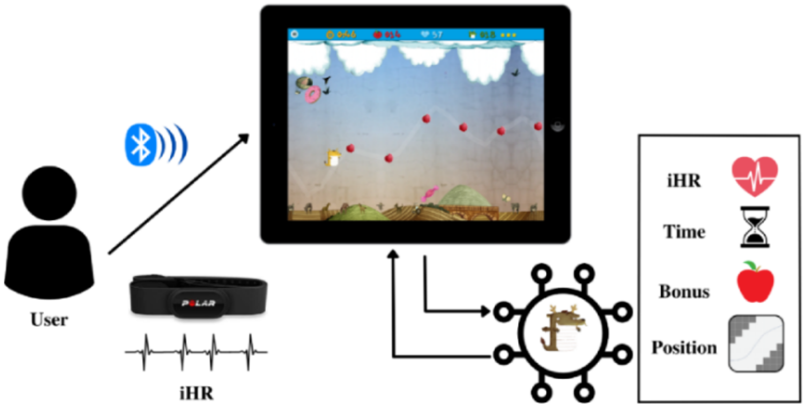
Programing Language and Functionalities

The architecture of the app consists of two parts: (1) the base of the game and (2) the container of the app and the communication with another device. The base of the game refers to the visual part, the game's engine, screen management, menus, and navigation. This entire part has been implemented with HTML (WHATWG) assisted by CSS (World Wide Web Consortium) and JavaScript (Oracle Corporation) technologies, so that it can be run in any web browser, whether hosting the application on a web server or running it directly on a local computer or mobile device. Note that opening the game in a web browser will not allow the use of the sensors and hardware; therefore, on a web browser, the game can only run in the test mode. Nonetheless, in the test mode, it is still fully functional using the cursor on a computer keyboard or by tapping on the screen of a mobile device, which allows testers to move the character up and down the screen manually.

The container refers to what allows the game to be installed as a mobile app on an Android or iOS operating system. In addition, it provides the necessary functionality to access the camera of the device and process the images as well as to establish Bluetooth connections with HR sensors and process the collected data. In this case, data processing is used in the game as input commands, replacing the usual input methods, including the keyboard or touch screen (for testing purposes). That is, it is with iHR data (from real-time RR intervals) that the user can move the main character up and down the screen using the variation of each iHR beat with respect to the previous one. This app container was implemented using a cross-platform environment for writing applications for Android and iOS operating systems called Titanium SDK (TiDev, Inc).

The game engine is written in JavaScript and is based on a constant loop where, at each step, the current position of the character is evaluated with respect to its environment (screen boundaries, obstacles, and prizes) and the input of the user (iHR data; Figure 5). The game engine, menu screens, and navigation are written in web languages compatible with any browser. Finally, both operating systems (Android and iOS) allow the introduction of web components within the app to reproduce web code (ie, HTML+CSS+JavaScript) as if it were part of the same app. The current app takes advantage of this feature to separate the game from the app's container, which allows communication via Bluetooth with other devices. When the container receives a command via Bluetooth, the app container code sends the corresponding interpretation of this command to the game part. For example, when instantaneous HR data are received over Bluetooth, the app container unpacks the received frame, obtains specific iHR data, and sends it to the game, which interprets it and moves the character. Figure 5 shows a game flow representation, where the user wearing a chest band sends iHR signals via Bluetooth and the game algorithm evaluates iHR, time playing, Bonus achieved, and position on a constant loop.

Figure 5. Game flow representation. iHR: instantaneous heart rate.



Data Collection and Bluetooth Connection

Before communication occurs between the sensor (HR sensor) and the FitLab Game, a connection must be established between the entities. Such a connection is established via Bluetooth and is known as pairing. In this type of connection, one of the devices acts as a host or receiver of data and the other acts as a client or sender. The device acting as a receiver can establish connections with multiple sending devices, but a sending device can only connect to a single receiver. Currently, the present app allows only 1 sender to be connected to the device because each game is calibrated to a user's iHR.

It should be noted that the iHR reading device used for the FitLab Game could be any, but it must offer a Bluetooth low energy connection so that the app can obtain the data. This version of Bluetooth can define specific data formats using standard attribute profiles (Generic Attribute Profile). This allows, for example, Bluetooth communication in the Heart Rate Profile mode to be established between the data sensor (the sender) and the app (the receiver). In this way, the receiver can interpret the data in whichever format it is packaged and can obtain the iHR information regardless of the manufacturer and model of the sending device, as long as it uses Bluetooth low energy with the Heart Rate Profile mode.

At present, when the app is opened, the user is asked to select the data entry method. When Bluetooth is selected, a screen with detected nearby Bluetooth devices is displayed. The list of displayed devices is filtered to show only those in the Heart Rate Profile mode. The user can select a device from the list of available devices and establish a connection. This process may take 1 or 2 seconds, and the user receives a confirmation if the connection has been successfully established or if an error has occurred. Once the connection is established, the application takes the user to the game's playing menu.

Data Processing

For each game carried out in the app, iHR data are collected together with other metadata, including the start and end times of the game, a user's identifier code, an ID assigned to the session, the level of the game played, the Bonus achieved, and the iHR calibration. All these data are packaged, saved in the container of the app, and can later be exported for analysis. Multiple user sessions can be stored locally, that is, in the application, but an internet connection is required to export the data to a server. Note that the game does not need an internet connection to work, and a wireless Bluetooth connection between the sender and the receiver in proximity is sufficient. For research purposes, the sessions that are temporarily saved on the device are accessible from a configuration menu by an application manager. To export data, the manager needs to select the desired sessions and indicate an email address to which the anonymized data will be sent, that is, identified by user codes and never by names or other identifying data.

Phase 2: Pilot Study

Study Sample

A total of 16 participants (9 men and 7 women; mean age 23, 0.69 years) were divided into 2 groups: a control group (4 men and 4 women; mean age 23.25, SD 0.99 years) and an experimental group (5 men and 3 women; mean age 22.75, SD 1.01 years). All participants were aged >18 years and did not present any cardiovascular disorder or take any medication that could affect HRV. The descriptive statistics of the participants are presented in Table 1. All participants, selected via a convenience sample of university students, were volunteers, and all participants provided written informed consent.

Table 1. Descriptive data of the participants (N=16).

Variable	Control group (n=8)	Intervention group (n=8)	All participants (N=16)	*P* value
Gender (woman), n (%)	4 (50)	3 (38)	7 (44)	.61
Age (years), mean (SD)	23.25 (2.82)	22.75 (2.87)	23 (2.76)	.73
Height (cm), mean (SD)	170 (10.53)	173.88 (8.34)	171.94 (9.39)	.43
Weight (kg), mean (SD)	66.5 (13.86)	66 (9.41)	66.25 (11.45)	.93
BMI (kg/m^2), mean (SD)	22.84 (3.38)	21.78 (2.50)	22.31 (2.92)	.49

Material and Instruments

Control Measures Self-Report

Before attending the session, participants were recommended, by email, to avoid taking nonessential drugs (up to 24 hours before the session) as well as caffeine, smoking, or any other psychostimulant (up to 2 hours before); alcohol (10 hours before); heavy meals (3 hours before); or eating in general (1 hour before). They were also asked to avoid high-intensity physical activity or any unusual exercise (20 hours before), to sleep for at least 6 hours, and to wear comfortable clothes to the laboratory. A brief questionnaire was administered immediately before the laboratory sessions to record these conditions. The participants were also asked to report their weight and height. In addition, the BMI was computed based on the participants' reported height and weight. This measure was used as a control variable between the groups because of its possible influence on HR [27].

Polar Band H10

An H10 cardiac chest band (Polar Electro) was used to record the RR interval signal (transformed to iHR), as validated previously [28]. The signal was sent and collected to the FitLab Game App (iOS version 1.0, build 1; Health&SportLab SL), which was active on an iPad Air 2 (version 12.1.4).

Questionnaire of Satisfaction With FitLab Game

An ad hoc satisfaction questionnaire based on the proposals of different works [29-31] was tailored to our research purpose. The questionnaire was created to collect participants' information about the following factors (see *item number* in brackets): (1) usefulness, (2) ease, (3) enjoyment of the game, (4) personal ability, (5) intention to use, (6) clarity of the goal of the game, (7) controllability of the game, (8) strategic approach, (9, 10, and 11) flow, (12) feedback, (13) educational aspect, (14 and 15) motivation, and (16) design aspects. Each factor was represented by a single item, except for flow and motivation, which consisted of 3 and 2, respectively. The participants responded to the questionnaire using a Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Mean scores >3 can be considered as positive, 3 as neutral, and <3 as negative. Items related to the techniques used to modulate HR were not included in the control group. The average total score was computed based on participants' responses, providing a general satisfaction score.

Procedure

The study consisted of 1 individual session per participant, which lasted for approximately 35 minutes and took place in the Basic Psychology Laboratory of the Universitat Autònoma de Barcelona. The day before this session, each participant was provided a list of recommendations, based on the *Control Measures Self-report*, to record variables that may affect HRV, including physical activity and intake of caffeine, psychostimulants, alcohol, drugs, and food. At the beginning of the session, the H10 cardiac band was placed on the participant's chest so that they could become familiarized with the sensation of the band. A few drops of conductive gel were applied to the band to facilitate good contact with the skin. Once the band was placed, the participant answered the *Control*

Measures Self-report questionnaire. The participants were then introduced to the FitLab Game for the first time. Play time was divided into 3 parts, with the first and third parts being recorded for the study (Figure 6). In part 1, the baseline phase, each participant played 2 levels of the game to familiarize themselves with the functioning of the app, without time constraints. In part 2, the practice phase, participants practiced on a different level for 6 minutes, or a maximum of 3 levels. Finally, in part 3, the test phase, each participant played the same 2 levels as in part 1.

Figure 6. Example of screens of the game that participants played. Testing consisted of 3 parts (part 1: baseline phase, part 2: practice phase, and part 3: test phase).

A few techniques to consciously control iHR (and thus manage HRV) were explained to the participants in the experimental group but not to those in the control group. To increase HRV (and reduce iHR), it was recommended to either breathe at a pace where the exhalation was longer than the inhalation [32-34] or to hold one's breath [35]. To reduce HRV (and increase iHR), participants were instructed to slightly hyperventilate [36], to perform muscle movements [37], or to swallow saliva voluntarily all at once [38].

For each level and session that the participants played, the FitLab Game calibrated a baseline iHR, which allowed the game's character to be placed in the center of the screen, in such a way that the starting point and the difficulty of the iHR series were equal for all participants. Then, participants had to follow the same pre-established route corresponding to each level and session, collecting apples (Bonus), which marked the correct route, and avoiding other elements such as unhealthy foods, tobacco, or the upper and lower limits marked by the floor and ceiling of the screen. To follow the route (or avoid certain elements), the main character had to move up or down the screen, which was controlled by changes in iHR. Participants in the control group were given no instructions on how to do so, whereas participants in the experimental group were explained the techniques mentioned in the paragraph above. All participants started the game with 20 lives, and the game ended when they ran out of lives or when they reached the end of the level without losing all these lives.

Data Analysis

Descriptive statistics are reported as means and SDs. A 2 × 2 multivariate analysis of variance following a general linear model was used to analyze the differences between the baseline and test situations. The baseline values were calculated as the average of the 2 games played in part 1, and the test values were calculated as the average of the 2 games played in part 3 (Figure 6). This statistical analysis was carried out to analyze the baseline versus test data obtained from HRV parameters, as well as time and Bonus, all separately. Statistical analysis was performed using SPSS (version 28.0; IBM Corp).

The raw RR interval values recorded by the Polar H10 cardiac chest band were processed to remove artifacts owing to false positive or false negative detections; afterward, the RR intervals were filtered, and the corresponding iHR values were shown in real time on the screen when the participant was playing. The same processed RR interval values were saved and analyzed to calculate the HRV parameters. A time domain HRV analysis was performed to calculate average RR intervals (RR mean), SD of RR intervals, root mean square of differences between adjacent RR intervals (RMSSD), and percentage of consecutive RR intervals that differ by >50 ms between them. A frequency domain analysis was used to calculate the low-frequency band (low frequency [LF]; 0.04-015 Hz) and high-frequency band (high frequency [HF]; 0.15-0.4 Hz). HRV analysis followed the guidelines recommended by the Task Force of the European Society of Cardiology and the North American Society of Pacing and Electrophysiology (1996). HRV analysis was performed using MATLAB (R2021 update 3 for 64 bits Windows; MathWorks).

Ethics Approval

This study was conducted according to the local ethics committee for human experimentation (protocol code CEEAH-5745).

Results

Change in Gaming Performance (Pilot Study)

To analyze the participants' performance in the game, the change in the number of apples collected (Bonus) and the total time played in seconds (Time) were considered, as presented in Table 2. No significant changes were found in the baseline versus test situation when comparing the experimental and control groups. However, there was a tendency for both groups to have increased Bonus and Time from the baseline to the test condition.

Table 2. Game outcomes in baseline and test phases in the control and experimental groups.

Variables	Baseline, mean (SD)	Test, mean (SD)
Bonus		
Control	16.75 (10.91)	18.06 (9.54)
Experimental	15.75 (5.34)	20 (10.15)
Time		
Control	91.08 (26.79)	109.05 (58.17)
Experimental	91.07 (26.79)	116.67 (52.31)

Participants' Satisfaction

The satisfaction questionnaire was completed by 13 (81%) of the 16 participants. Overall, participants expressed high satisfaction with the FitLab Game, reporting positive experiences, with a total score of 3.87 (SD 0.42) for the control group and a total score of 4.30 (SD 0.50) for the intervention group. The intervention group answered 16 questions, with 4 specific questions related to the techniques used during the game. Table 3 provides an extended description of the items and their scores for each group.

Table 3. Items and scores of the ad hoc game's satisfaction questionnaire for the control group (n=5) and intervention group (n=8)[a].

	Items	Control group, mean (SD)	Intervention group, mean (SD)
1	"I can learn self-control techniques better and faster with games like this."	N/A[b]	4 (0.53)
2	"Using games like this would be easy for me."	4.2 (0.45)	4 (1.07)
3	"Playing to learn techniques is more fun than following a pacer."	4.6 (0.55)	4.87 (0.35)
4	"I would be able to play this game even if nobody was there to teach me."	N/A	3 (0.76)
5	"In the future, I would play if I wanted to learn how to control my heart rate."	4.2 (0.84)	4 (0.76)
6	"The aim of the game was clear the whole time I was playing."	4 (1.22)	5 (0)
7	"The instructions for functionality were clear."	N/A	5 (0)
8	"While playing, I understood how to achieve points and how to end the game successfully."	4.2 (1.30)	4.6 (0.52)
9	"While playing, I was only thinking about the game."	3.6 (1.14)	4.75 (0.46)
10	"While playing, I forgot everything else around me."	4 (1)	4.5 (0.53)
11	"While playing, I didn't realise how much time was passing."	3.2 (0.84)	4.13 (0.83)
12	"When I did something in the game, I knew if it was right or wrong."	3.4 (1.82)	4.25 (1.04)
13	"By playing I learned how the techniques affect my heart rate, and how I can modify it."	N/A	4.13 (0.64)
14	"The game format increased my motivation to continue playing and achieve more bonus points."	3.4 (0.89)	4.63 (0.52)
15	"A game that applied different breathing techniques would increase my interest in this topic."	4 (0.71)	4.63 (0.52)
16	"The levels are fun and esthetically pleasing."	4.2 (0.45)	4.38 (0.74)

[a]Total score: control group—mean 3.87 (SD 0.42); intervention group—mean 4.30 (SD 0.50).

[b]N/A: not applicable.

Change in HRV Parameters

When analyzing the changes in HRV before and after the game, the results showed some differences between the experimental and control groups (Table 4). In particular, the experimental group showed a decrease in RR mean from baseline to test, which was different from the increase observed in the control group (*P*=.02; Figure 7). In contrast, the experimental group showed a decline in RMSSD from baseline to test, which was more pronounced than that in the control group (*P*=.04). No other HRV parameters presented a significant or tendential change.

Table 4. Multivariate analysis of variance of heart rate variability variables in baseline and test conditions in the control and experimental groups.

Variables	Baseline, mean (SD)	Test, mean (SD)	*P* value
RR mean[a]			.02
Control	800.33 (109.02)	816.89 (106.59)	
Experimental	1004.52 (148.41)	930.90 (132.45)	
SDRR[b]			.56
Control	62.55 (24.12)	65.64 (20.16)	
Experimental	111.35 (33.97)	109.81 (32.44)	
RMSSD[c]			.04
Control	43.10 (19.96)	41.60 (20.16)	
Experimental	93.80 (40.71)	80.07 (31.73)	
pNN50[d]			.36
Control	23.83 (17.53)	20.77 (17.25)	
Experimental	42.90 (18.63)	34.64 (17.52)	
LF[e]			.39
Control	3063.58 (2789.61)	2595.49 (2190.80)	
Experimental	6612.13 (3438.65)	6972.52 (3760.22)	
HF[f]			.10
Control	661.70 (458.82)	739.14 (547.80)	
Experimental	2985.17 (2311.75)	2046.96 (1594.17)	

[a]RR mean: average RR intervals.

[b]SDRR: SD of RR intervals.

[c]RMSSD: root mean square of differences between adjacent RR intervals.

[d]pNN50: percentage of consecutive RR intervals that differ by >50 ms between them.

[e]LF: low frequency.

[f]HF: high frequency.

Discussion

Overview

The aim of this study was 2-fold: to develop a serious game that teaches the user to self-regulate iHR using HRVB and to carry out a pilot study to test the game with participants. A total of 16 participants took part in the pilot study and were divided into a control group and an experimental group. The results were analyzed in 2 parts: one focused on changes in the performance of the game and the other on fluctuations on HRV parameters. The results related to the usefulness of the game are discussed in the *Game and App Performance* section.

Game and App Performance

Analyzed globally, the gaming performance of all participants was in line with the results of another gaming study [39], in which the participants played a biofeedback game 6 times and both the control group that received simulated feedback and the experimental group that received physiological feedback improved their gaming performance. These results indicate that playing a given game, in itself, leads to improvement in its final score through repeated training or habituation. That is, both groups got to experiment and learn how to move the game's character. Regarding the differences in performance between groups, the results showed that the experimental group had a greater improvement in all indicators compared with the control group, even though the differences were not significant. The experimental group showed a greater improvement in Bonus score (increase of 4.25 Bonus points in the test with respect to the baseline), compared with the control group (increase of 1.31 Bonus points in the test; Table 2). The same trend was observed in the total playing time, where the experimental group kept playing 7.6 seconds longer than the control group, but these results were not statistically significant (Table 2). All these results are consistent with the idea that the application of specific strategies in the experimental group could have improved the self-regulation of heart variability, more than simply practicing the game (as shown with the control group). However, these results should be interpreted with caution because of the small sample size and the high values of SDs shown in Table 2.

In our study, a few gamification techniques were introduced to increase players' desire to engage with the tasks. General techniques include having a goal to aim toward, a set of rules to follow, a challenge to complete, and *real-time* feedback to tell the player how he is doing and how close he is to completing the goal. More specific gamification techniques included Bonus points, increasing challenges, and performance graphs. Reynard et al [40], in a systematic review and meta-analysis of digital interventions for emotion regulation, found that digital game interventions consistently provided stronger evidence compared with other types of digital interventions. In this review, 64% of digital game studies provided feasibility for engagement, implementation, adherence, expectations, and transference to real life. However, they did not explain which elements of the specific game design were responsible for this feasibility. For their part, Maher et al [41] concluded that gamified apps were used substantially longer than nongamified apps. Other studies highlight specific game elements that impact health behavior and achieve adherence, similar to digital rewards, such as points, badges, or rewards that we used in our game [42]. Similarly, in the design of our game, we complied with five gamification principles relating to the motivation of the user [43,44]: (1) meaningful purpose, as the goal of the users participating in the study was to learn a technique to improve their health; (2) meaningful choice, as users could control how they achieved their goal of eating the apples on the screen; (3) supporting player archetypes, as in our game, the initial iHR level is individualized based on the user characteristics; (4) feedback, as the user's actions to control the movement on the screen based on their own cardiac variability affect progress, and it is clearly communicated; and (5) visibility, as the amount of progress made in each level (apples, points, and Bonuses achieved) is visible at all times. Most of these principles are reaffirmed by the users' responses to the subsequent questionnaire, as discussed in *Participants' Satisfaction* section. Thus, the different techniques applied in the present serious game could contribute to behavioral changes, such as increasing players' engagement with the tasks and adhering to the use of the game. For example, the instant feedback provided by the game may have helped produce high engagement and enjoyability for the participants, as noted by Siriaraya et al [45]. At the same time, the fact that the levels of the game are adapted to each participant's cardiac recording means that each person plays in a personalized environment, which is thought to increase motivation toward the game [46]. Finally, regarding the app's functionality, we highlight the possibility of using either Bluetooth devices or photoplethysmography sensors [47], allowing participants to play in different contexts and with different resources.

The serious game created for this study can be used in multiple situations (in the long term). The game provides flexibility to play in new scenarios, depending on the specific training or situation goals set by the player. Furthermore, there is a menu for practice in which the players can play to test different techniques. Therefore, this game supports repetitive practice as an effective training method. In addition, the game uses the Bonus and time measurements to self-track the learning progression. As the players enhance their level of expertise, the Bonus points and time increase accordingly. This mechanism ensures that as the player improves, they are rewarded with higher Bonuses and more time in the level, motivating them.

Participants' Satisfaction

Participants expressed an overall positive satisfaction with the FitLab Game, with a greater total score in the intervention group (4.30 out of 5) than in the control group (3.87 out of 5). As Table 3 shows, this higher satisfaction in the intervention group is also supported by the fact that all the items that both groups had in common showed a higher score of 4 (out of 5) only for the intervention group. Both groups considered the game to be easy and fun (punctuations >4 for both groups). The goal and strategic approach to achieve Bonuses and continue playing were clear for both groups, with scores >4. Furthermore, both groups expressed positive intention (score >4) to continue playing the FitLab Game and learn how to control their HR in the future. The participants in the intervention group rated the feedback provided by the game more positively (score >4) compared with the control group (score >3). Regarding the experience of flow during the game, although both groups scored >3, the intervention group scored >4 across the 3 items. Similarly, in terms of motivation, the intervention group scored >4 and the control group scored >3. Finally, both groups found the screens visually appealing and balanced in terms of colors, with scores >4.

As shown in Table 3, the techniques provided to the intervention group were found to be useful in establishing control over iHR and were considered important for playing successfully. Thus, the neutral score in the personal ability factor indicates that the instructions based on different techniques for controlling iHR should be considered necessary for success in the game. The gameplay was understood by both the groups, and the game was generally perceived as easy and enjoyable. With regard to flow and motivation, the intervention group reported a more favorable experience with the game. This can be explained by the use of techniques that enable participants to exert voluntary control over the characters, thereby enhancing the game experience through the interactive component of the game. These findings are in line with those of previous studies, indicating that a gamified visualization component results in higher intrinsic motivation [48]. It is worth noting that the participants expressed a strong interest in continuing to play the FitLab Game in the future, reflecting their engagement and willingness to play to learn about cardiac variability control.

On the basis of the results presented, we propose an extensive use of the game with the main goal of helping individuals learn how to self-regulate their cardiac variability to achieve emotional self-control. This could be applied in different contexts, including clinical (eg, in anxiety or stress disorders) and nonclinical populations. This is in line with the results of a systematic review where consistent evidence was found for reduced negative emotional experience provided by digital games [40]. Ideally, these games should be used under the supervision of health professionals to facilitate learning-specific techniques for controlling cardiac variability. This is reaffirmed because the only response <4 in the specific items for the intervention group is for the item: "4 I would be able to play this game even if nobody was there to teach me" (rating of 3 out of 5). Nonetheless, as shown in Table 3, participants reported that the game was easy to understand and play (item 2), indicating that both the control and experimental groups understood the game well.

HRV Analysis and Biofeedback

Regarding HRV, the results of the pilot study showed some differences in the cardiac behavior of the experimental and control groups (Table 4; Figure 7). This suggests that the strategies used by the experimental group to compete in the game improved their control of cardiac variability, which in turn may have enhanced their performance. Owing to its pilot nature and limited number of participants, the precise reasons underlying the relationship between control of cardiac variability and performance cannot be conclusively determined. Nonetheless, it is possible that the results reflect the activation and the control of attention mechanisms in the experimental group. If we consider that the game requires a certain level of concentration and attention to play, especially if the participants are remembering and applying the techniques that were just learnt, some arousal level is needed, reflected in a reduction in the activity of the parasympathetic nervous system, as shown by a reduction, although not significant, in the experimental group (HF parameter) compared with a slight increase in the control group. This result is consistent with the increase, but not significant, in the LF values in the experimental group compared with the decrease in the control group. There is evidence that higher LF values are related to a greater activation of the sympathetic nervous system [49]. At the same time, a significant reduction in cardiac variability was observed in the experimental group, as shown by the RR mean and RMSSD parameters. The set of previous results could explain the improvement in the control of arousal or activation in the experimental group. In line with this idea, Fuentes-García et al [50] found that in chess games, the player's level and the difficulty of the game determined the activity of the ANS of the individuals, with higher demands in attentional focus resulting in lower HRV. Thus, in this study, the experimental group may have shown reduced vagal activity and cardiac variability because they were given techniques to control their HRV, requiring greater attention when playing [51]. In that sense, HRV is an indicator that the experimental group was active and applying what had been taught.

An array of scientific papers highlights the potential of incorporating biofeedback into different types of digital game interventions, including virtual and augmented reality, internet therapy, biofeedback and neurofeedback, digital games, and web-based programs. In a systematic review by Reynard et al [40], 39 interventions were identified, 10% of which were based on biofeedback. The effectiveness and impact of incorporating biofeedback into digital games have been tested in a range of topics, from stress reduction to physical rehabilitation [52]. For instance, Knox et al [53] and Wenck et al [54] studied biofeedback-driven digital game interventions for stress levels before the emergence of smartphones and concluded that symptoms of anxiety and depression were significantly alleviated in children. Similarly, Jerčić and Sundstedt [55] showed that visual and gameplay biofeedback in serious games supported emotional regulation skills. Moreover, aside from the impact on the psychophysiology of individuals, digital interventions appear to be accessible and attractive compared with one-to-one clinical therapies [40], particularly for the younger population [56]. Lüddecke and Felnhofer [57] demonstrated that biofeedback interventions increased the motivation and long-term participation of users in health-related interventions. Finally, games that incorporate biofeedback, compared with other digital interventions, seem to provide the most evidence for emotional skills transference to real life [40]. In conclusion, there is a growing body of research that emphasizes the utility of incorporating biofeedback into digital game interventions for its attractiveness and potential to enhance emotional regulation, among other benefits.

Returning to our study, our results seem to contradict most studies using the HRVB technique, which conclude that this technique helps improve HRV [58,59] with the general aim of achieving relaxation. However, this was not the case. These articles used set breathing paces, usually between 4.5 and 6.5 times per minute, as HRVB to induce relaxation [60,61]. For example, on the topic of gaming, Al Osman et al [62] used game-based biofeedback to control the activity of the ANS and showed that HRV increased following a controlled breathing rate. In contrast, the goal of this study was not to increase, maintain, or decrease HRV but to teach participants to control its rises and falls through various techniques, including breathing control, but not at a set pace. Thus, our study is not comparable with most other studies, given that we did not focus on breathing paces but rather on an array of techniques to teach the participants how to increase or decrease their HRV. These techniques include the voluntary production of apneas to suddenly increase cardiac variability [35], the performance of muscle movements to achieve a reduction in HRV (in line with Guidi et al [37]), or voluntary swallowing. This last strategy can produce changes in some HRV parameters in healthy people, such as SD of RR intervals, LF, and HF power [63], and effortful swallowing increases LF power and the LF/HF ratio [64]. On a practical level, in our case, these strategies allowed the player to move the character up and down the game screen because they provide rapid changes in cardiac variability.

Limitations and Future Directions

This study had 3 main limitations. The first limitation is the sample size of the pilot study. Even if the results show significance in the mean iHR (proportional to the RR mean) and RMSSD, they should still be considered preliminary. The second limitation is that participants were not monitored before and after the game but only during it. This means that the HRV indicators were collected as the game was being played, thus in an active state and not in a resting situation. Our interest was to test whether there were changes in the HRV parameters and game performance at all, as a pilot study, but in future studies, it would be interesting to observe the influence of our intervention on basal HRV.

Finally, most previous studies using techniques such as HRVB included a sample of clinical patients, unlike this study, which was conducted in healthy university students. For instance, Siepman et al [65] compared the effects of HRVB in both healthy people and individuals classified as depressed, showing that the latter experienced a significantly greater improvement in HRV, compared with healthy volunteers. Similarly, Pyne et al [66] reported that HRVB training reduces symptoms of posttraumatic stress in older people only. These studies highlight that HRV parameters seem to be difficult to alter with HRVB in healthy and younger people than in older or clinical populations, potentially explaining the results of this study, with few to no significant changes in some HRV parameters. In the future, a larger sample size of healthy university students or testing the FitLab Game in a clinical population could provide more consistent results. Finally, it would also be interesting to provide new strategies for the voluntary control of HRV, perhaps further refining the ones we have already developed in this study. It would also be necessary to deepen the swallowing strategy, as Yildiz and Doma [38] and Yıldız [67] concluded that spontaneous saliva swallowing can change some short-term HRV parameters significantly even in healthy people.

Conclusions

This study developed a serious game, called the FitLab Game, that teaches the user to self-regulate the iHR using cardiac variability biofeedback. The game was also tested with the participants in a pilot study. Overall, the FitLab Game appears to be a promising serious game because of its ease of use, high engagement, and enjoyability provided by the instantaneous feedback. The strategies learned by the experimental group to compete in the game, which included the voluntary production of apneas, muscle movements, and voluntary swallowing, improved the self-control of cardiac variability and, in turn, may have enhanced performance. A significant reduction in cardiac variability observed in the experimental group, based on the RR mean and RMSSD parameters, could explain the improvement in the management of arousal or activation compared with the control group. Thus, the application of specific strategies in the experimental group may have improved the self-regulation of HRV more than simply practicing the game.

The usefulness of HRV as a health indicator is well known, and HRV biofeedback is considered an established intervention in the clinical context. Thus, learning simple and voluntary strategies through the developed game can help improve self-control and arousal management. Ultimately, with sufficient training, the game can become a relaxation technique for the general population or clinical populations, or, for example, an activation technique for athletes in certain situations.

Abstract

Background: Opioid misuse is a pervasive, worsening problem that affects the health of people throughout the United States, including adolescents. There are few adolescent-focused interventions designed to educate them about opioid medication safety. The MedSMARxT: Adventures in PharmaCity, is a serious educational video game that teaches parents and their youths about safe opioid practices.

Objective: This study aimed to elucidate parent's perceptions of MedSMARxT: Adventures in PharmaCity and its potential use by parents and their adolescents.

Methods: Parents of adolescents aged 12 to 18 years who live in the United States were recruited from April to October 2021 via Qualtrics research panels, social media, email listserves, and snowball sampling. The study participants played MedSMARxT: Adventures in PharmaCity for 30 minutes and then participated in a 30-minute postgame interview via WebEx (Cisco). Questions were developed and piloted to examine adults' perceptions of the game. Participants were asked three sets of open-ended questions: (1) questions about the game and elements of the game, (2) what they learned from the game, and (3) questions about their experience with games. Audio recordings were transcribed verbatim. Interview transcripts were coded using content and thematic analysis by study team members to identify major themes and subthemes from the data.

Results: Parent participants (N=67) played MedSMARxT: Adventures in PharmaCity and completed a postgame interview. Analysis extrapolated four primary themes from the data: (1) participant gaming experience, (2) perception of game features, (3) educational purpose of the game, and (4) future use of the game. Most participants (n=56, 84%), had at least some experience with video games. More than half of the participants (n=35, 52%) participants, had positive reactions to the game characters and scenes depicted in MedSMARxT: Adventures in PharmaCity and stated they were realistic for adolescents. Most participants (n=39, 58%), would recommend the game to others. Significant difficulties with gameplay navigation were reported by 38 (57%) participants, as well as a slow game pace. All participants were able to accurately identify the overarching goal of the game: opioid or medication safety. The game reinforced existing knowledge for participants, though many (n=15, 22%), reported a new awareness of the need to store opioid medications in a locked area and the availability of medication disposal drop boxes at pharmacies. Participants stated that they would recommend the game for future use by families and youths in various health care and non–health care settings.

Conclusions: The use of a tailored serious game is a novel, engaging tool to educate adolescents on opioid safety. MedSMARxT: Adventures in PharmaCity can be used as a tool for parents and adolescents to facilitate meaningful dialogue about safe and appropriate opioid use.

Introduction

Background

The opioid crisis has palpable impacts throughout the United States across all demographics. Seldom can one go a significant amount of time without hearing about the epidemic's dire impacts on health and well-being. Death rates from opioid misuse have nearly tripled since 1999, and opioids were involved in an estimated 80,816 deaths in the United States in 2021 alone [1,2]. Curbing opioid misuse has been a long-standing focus of policy and governmental efforts, with the White House declaring the opioid epidemic a public health emergency in 2017 [3].

Youths are just as vulnerable to the growing opioid crisis as adults. In a survey collected by the Centers for Disease Control and Prevention in 2019, approximately 14% of high school students reported misuse of prescription opioids during their lifetime [4]. Opioid misuse encompasses taking opioids outside of their prescribed regimen, such as taking more than prescribed, using them in the absence of pain, or taking them after expiration. Among adolescents, misuse often begins at home, where leftover opioid medications enable misuse [5,6]. Adolescents tend to model the behaviors of their parents regarding their opioid prescription usage [7]. Research shows that the proportion of adolescents and young adults with opioid-related health problems has increased over time despite a decrease in the total number of adolescent and young adult personal opioid prescriptions during the same period [8]. Out of all the adolescents and young adults who experienced an opioid-related problem, 40% had received a personal prescription for opioids in the past year while 48% had a family member prescribed an opioid in the past year. Even adolescents who are prescribed opioids and take them appropriately are 33% more likely to develop problems such as opioid dependence or lifelong patterns of misuse [1].

However, research has shown that educating parents can improve their behavioral intentions and reduce the likelihood that they will store unused opioid medications in the home [9-11]. Alongside rising rates of adolescent opioid misuse, youths have reported misconceptions about safe opioid use practices, including inaccurate identification of medications that are opioids, improper storage and disposal techniques, and inappropriate sharing of prescribed opioids with others [12]. Due to the vulnerability of adolescents and their limited knowledge about opioid medication safety, it is essential to create tailored, educational interventions that teach youths and families about the importance of safe prescription opioid use.

Currently, there is a lack of interventions tailored to adolescent education on opioid medication safety [13-16]. Previous literature suggests that parents and youths are receptive to game- and web-based opioid misuse prevention programs, citing a belief that gamified educational methods would improve adolescent engagement [17,18]. These studies have also shown that serious educational games may enhance the retention of information, accelerate learning, and increase accessibility to educational material. Other health-focused games have shown effectiveness in improving key behavioral intentions and improving education for youths [18-21]. Novel approaches to engaging youths can be effective and are paramount in combating the opioid crisis [22,23]. One such approach is the use of a serious game. Serious games are video games designed to impart knowledge or improve social-behavioral outcomes for players wherein the primary objective is not entertainment [24].

MedSMARxT: Adventures in PharmaCity

Overview

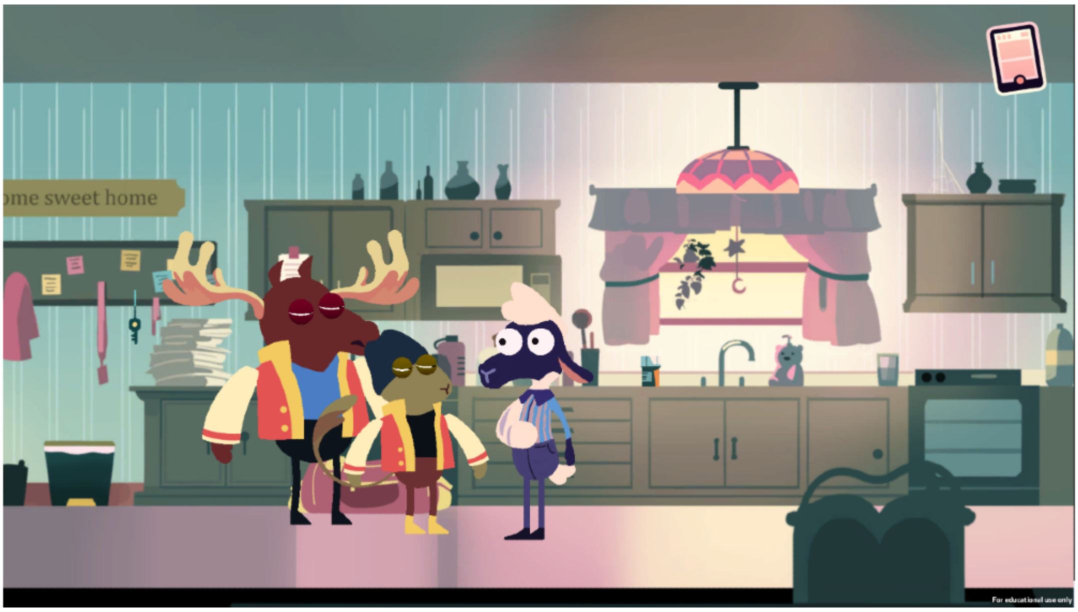
MedSMARxT: Adventures in PharmaCity is a theory-driven, adolescent-focused serious game developed to educate adolescents and their families on how to safely manage complex, real-life situations involving prescription opioid medications [25,26]. By playing the game, youths and their family members (such as parents) are able to identify best practices for the safe and responsible management of opioid medications with a focus on appropriate disposal, proper storage, and preventing medication sharing. The game scenarios were created with the interdisciplinary study team comprised of game designers and developers, health services researchers, pharmacists, an adolescent health physician, and an addiction medicine physician. The scenarios were further assessed by adolescents and young adults who overall found the scenarios to be realistic and relevant. The game content, game design, and scenarios were informed by several extensive studies previously conducted by the study team to understand opioid safety knowledge games of adolescents and their preferences for game-based education [9,14-16,25,26]. Findings from these studies showed that adolescents significantly lacked information on safe opioid storage and disposal; hence, a critical knowledge gap that needed to be addressed via game-based learning. Parent involvement in medication-related behaviors (such as medication storage and disposal) remains an important protective factor against adolescent prescription medication misuse [27]. Therefore, the inclusion of parents in the feedback and development was key to creating an intervention that would facilitate adolescent education and promote family medication safety.

The game's format was a responsive narrative wherein players make choices that affect the game's outcomes, such as choosing their own adventure. Players play as an anthropomorphized sheep, Shan, who recently broke their arm. Players must use critical thinking and decision-making to select the correct (safest) choices regarding opioid use through 5 levels simulating real life. If players make a decision that is unsafe, they are presented with an opportunity to replay the level. The game is played using an internet-enabled computer via a web browser.

Level 1

A Quiet Sunday Afternoon focuses on teaching the player about the safe storage of opioids and requires the player to appropriately store opioids in a locked cabinet before Shan's friends gain access to the medications and overdose (Figure 1).

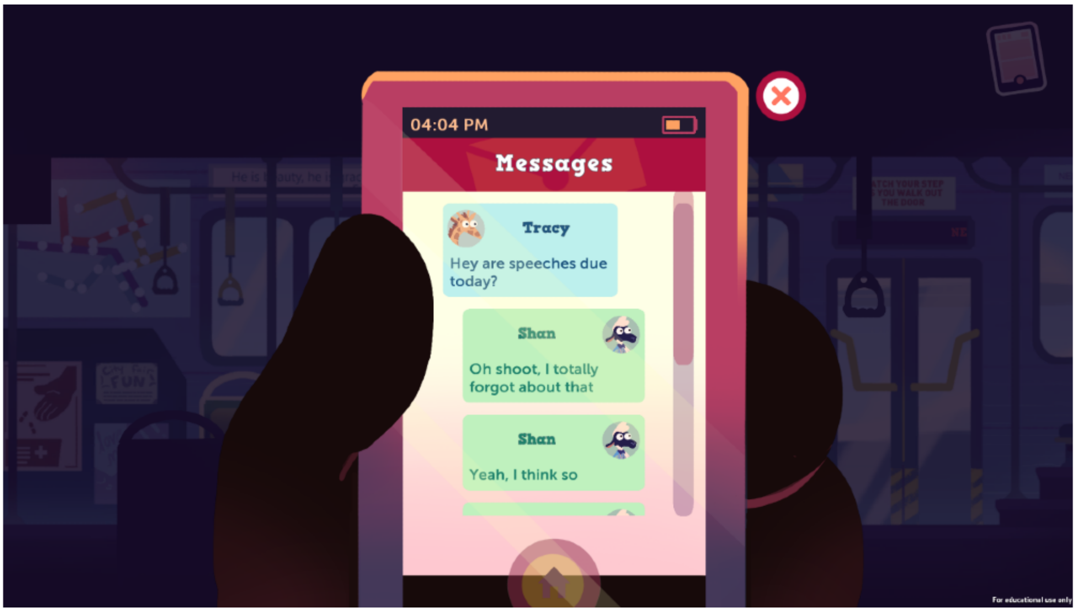
Figure 1. Game level 1.



Level 2

Monday Morning Bus Ride, in this scene, the player is in pain and forgets there was an important assignment due that day (Figure 2).

Figure 2. Game level 2.



Level 3

A Persuasive Speech at School teaches the player not to take others' pain medications through peer pressure from a friend and discusses the negative consequences of taking someone else's prescription medication (Figure 3).

Figure 3. Game level 3.

Level 4

Bus Ride Home teaches the player not to share their medication with others and reinforces the risks of sharing medications. This game level also introduces the use of Narcan through an encounter with a stranger on the bus who acts as if they are in pain and needs relief (Figure 4).

Figure 4. Game level 4.

Level 5

Last Minute Chore shows the player the correct approach to dispose of opioid medication and that medication disposal drop boxes are available at local pharmacies (Figure 5).

Figure 5. Game level 5.

Study Objectives

The purpose of this study was to examine parents' perceptions of the MedSMARxT: Adventures in PharmaCity game. Specifically, the study assesses parents' perceptions of the game features, what participants learned from the game, and their gaming experience.

Methods

Ethics Approval

This study was approved by the University of Wisconsin-Madison's institutional review board (2020-1638) on January 5, 2021.

Sampling and Recruitment

From April to October 2021, a national sample of parents was recruited via Qualtrics research panels, social media, email listserves, and snowball sampling. The study team partnered with Qualtrics to identify and recruit from preexisting research panels. Social media sites included Facebook (Meta Platforms), Instagram (Meta Platforms), Reddit, and Twitter. Listserves came from the University's mass email system and the study team's own list of youths and parents. Eligible participants were parents of adolescents aged 12 to 18 years who live in the United States, could read, speak, and understand English, and had access to a computer with a working webcam. After screening for eligibility, parents were asked to provide consent and their contact information for scheduling purposes. Parents were then contacted to partake in the study and screened for eligibility by the research staff.

Data Collection

Study sessions were held via WebEx. Parents were told that the study was being conducted by a team of researchers interested in adolescent opioid misuse prevention and that they were looking for data to help refine their game. Parents were asked to play the MedSMARxT: Adventures in PharmaCity game for 30 minutes (or until they completed all 5 levels, whichever happened first), and answer follow-up interview questions. Data were collected through 30 minutes of gameplay and a 30-minute semistructured interview. Only participants and a member of the research staff were present during the data collection. The research team created interview questions to examine parent players' feedback on the game. Participants were asked three sets of open-ended questions: (1) about the game and elements of the game, (2) what they learned from the game, and (3) about their experience with games. Interview questions were developed for the purpose of understanding parents' perceptions of the game, confirming the salience of educational content, and characterizing the gaming experience of parents of adolescents. The study team used interview questions that had previously been pilot-tested and proved to be effective for examining adults' use of the game. The interview ended with, "Is there anything else you'd like to add?" to allow the participant to share any other thoughts or details that were not previously captured. Parents were compensated US $30 via an Amazon gift card for their participation in the study. Interviews were professionally transcribed verbatim using audio recordings collected through WebEx. The interview guide is shown in Multimedia Appendix 1.

Data Analysis

Two research team members (GAN and LLS) independently analyzed each interview transcript using NVivo (Lumivero) [28]. The main themes from participant responses were coded using content analysis followed by a thematic approach [29]. The coding members of the study team first familiarized themselves with the data by reading through each transcript in detail and then independently extrapolated codes. The research team members met regularly to discuss coding differences and develop a master codebook. The codes were then exported to Excel (Microsoft Corp) for further thematic analysis using an inductive and deductive approach to identify salient themes [30]. The primary investigator (OA) met with the coders to address any coding discrepancies and prevalent themes identified. Each coder identified themes and subthemes from the data based on code prevalence, and then the research team met to compare and finalize the results reported below.

Results

Participant Demographics

Feedback was elicited from 67 parent participants who played MedSMARxT: Adventures in PharmaCity. Participant characteristics are described in Table 1. Notably, 92.5% (n=62) of them identified as female, 77.6% (n=52) of them identified as White, and the mean age was 46.03 (SD 5.75) years.

As depicted in Textbox 1 below, four major themes were identified: (1) participant gaming experience, (2) perception of game features, (3) educational purpose of the game, and (4) future use of the game. A detailed description of the themes and prevalent subthemes that emerged from the data analyses is described below.

Table 1. Participant demographics (N=67).

Characteristics	Values
Level of education, n (%)	
High school	3 (5)
Associates or trade school	8 (12)
Bachelor's degree	26 (39)
Master's or PhD	30 (45)
Age (years), mean (SD)	46.03 (6)
Sex[a], n (%)	
Female	62 (93)
Male	5 (8)
Race or ethnicity[b], n (%)	
White	52 (78)
Black or African American	7 (10)
Hispanic or Latinx	3 (5)
Asian	2 (3)
More than one selected	3 (5)
Other please specify	0 (0)
Income (US $), n (%)	
Under $25,000	2 (3)
$25,001-$50,000	8 (12)
$50,001-$100,000	23 (34)
$100,001-$250,000	32 (48)
$250,001-$500,000	2 (3)
Employment status, n (%)

Western Pacific	7 (10)

[a]Three options were presented to the participants to select for their sex assigned at birth: “male,” “female,” and “other: please specify.”
[b]If participants only selected 1 category, that was their defined race; all other combinations of selections were defined as “More than once selected.”
[c]Regions are generated from participant zip codes according to the United States Postal Service data.

Textbox 1. Summary of themes and subthemes.

Participant gaming experience

- Experience with board and card games
- Experience with video games
- Experience with educational games

Perception of game features

- Levels
- Characters
- Graphics
- Navigation
- Pace

Educational purpose of the game

- Perceived main idea of the game
- Reading level
- Target audience
- Participant learning experiences

Future use of game

- Suggested improvements
- Applications

Theme 1: Participant Gaming Experience

Overview

Parents had a wide range of experience with games. Overall, participants preferred games that required strategy and discrete tasks to accomplish. Study participants enjoyed games that foster family or social interaction. Most parents reported at least some experience with video games and favorable impressions of educational games.

Experience With Board and Card Games

Many participants (n=32, 48%), reported playing board games, and overall, participants listed 70 different board games that they had played in the past. Social interaction with family and friends was a frequent motivator for participants to play board games. A smaller number of participants (n=13, 19%), discussed playing card games.

> *I play them with my family so it's something fun to do with my family or with my friends. […] So, it's more of a social thing for me, it's not a sit on my phone or computer and do something by myself.* [Parent 152]

> *I'm not a competitive person, but I like having something to do while you're sitting around and talking with someone else.* [Parent 184]

Experience With Video Games

Most participants (n=56, 84%), stated they had at least some video gaming experience. A few participants (n=3, 4%), considered themselves frequent players, and nearly half of the participants (n=30, 45%), considered themselves infrequent players. Of some participants (n=11, 16%), reported minimal to no experience with video games. Participants had used a variety of gaming platforms and systems, but mobile gaming was most frequently reported. Participants listed a total of 132 unique video games played. Common types of video games played include word, puzzle, and matching games.

Motivations for playing video games included a desire to pass time when relaxing or bored, to have a mental challenge, and to socialize with others, especially participants' own children. Lack of time, preferences for other forms of entertainment, and avoidance of violent themes were the 3 most frequent reasons for not playing video games. Some participants (n=18, 27%), stated nothing could be changed about video games to entice them to play more. Furthermore, a few participants (n=5, 7%), reported easier navigation would increase appeal and 5 (7%) participants mentioned that including goals would motivate them to play.

> *Yes, I have experience playing. I mean, I'm not sitting there every day playing, but I do play with the kids here and there. I like to mostly use my phone for games, but we do have consoles like the Xbox 1.* [Parent 194]

> *I'm really busy and I like to do other things with my time. I spend a lot of time on the computer at work and so when I come home, it's like, the last thing I want to do is spend more time on the computer.* [Parent 144]

Experience With Educational Games

Most participants (n=44, 66%), reported previous experience playing an educational game. Some of these participants (n=11, 16%), reported playing an educational game with their child in the past, and other parents (n=11, 16%), stated that educational games were a part of their career. Participants listed 36 unique educational games that they had previously played, which commonly included math games, crossword puzzles, early learning games, and trivia games.

Most parents (n=43, 64%), had a positive perception of educational games. Study participants perceived game-based learning as an appealing modality that is more engaging than traditional learning methods. Features such as the ability to learn from mistakes within the game and entertainment features were important to parents. A few participants (n=7, 10%), stated that educational games would be more beneficial for youths than adults.

> *I think it's really good. I mean, obviously, depending on what you're being educated on. But I think is a great way to learn and also kind of keep your interest as opposed to just reading it on the Internet or reading a book about it. It's a way to, a different way to learn to kind of keep it a little spicy, I guess.* [Parent 163]

> *I feel like your kids and adults enjoy playing them and have fun with them without realizing that it's a learning process because sometimes if you're like, "hey, we're going to teach you something," or "this is going to be educational," people automatically go to like, "this is going to be really boring." Um, so the good educational games kind of distract you from the fact that you're learning something by making it mostly fun. For younger kids, that's especially good.* [Parent 161]

Theme 2: Perception of Game Features

Levels

The most frequent positive descriptors of game levels included "cute" and "engaging." Participants appreciated the variety of game levels, which they reported represented real life. Parents appreciated the responsive narrative format which allowed the player to choose from multiple available actions, learn the consequences of wrong (unsafe) actions, and replay scenes to discover the appropriate actions.

A total of 35 (52%) participants reported that game levels were realistic. Some participants (n=10, 15%), specifically stated that the levels were applicable to the lives of adolescents. Only 3 (4%) participants reported that game scenes were not realistic due to the severity of the consequences portrayed. Some parents expressed uncertainty about whether adolescents encountered opioid misuse frequently. A small number of 3 (4%) participants noted that in the game a child's character performs actions they would not have their own child perform, such as medication disposal.

In level 1, some participants reported uncertainty around the correct actions to take, though many benefited from the educational content of this level. Level 3 was well-received by participants due to its depiction of an opioid misuse scenario with peer pressure which they felt adolescents may encounter. Level 4 was sometimes viewed as being unlikely, as participants felt that a stranger would not ask for pain medication from another person.

> *We don't necessarily know what kids are thinking. […] The conversation between Stan and Tracy was very interesting because you would never think […] that another teenager would offer their friend opioids, trying to help them out, nothing nefarious about it. But it's very dangerous. I mean, I could see how it could happen.* [Parent 199]

> *I think there were good choices, especially with the things at home and then the potential at school with somebody else having other medications. I liked that they were more of like, situations that kids might find themselves in, not trying to so, like, not actually having that seeking behavior, or, like, trying to purchase them from somewhere, but just happening, especially like, with the friend offering.* [Parent 172]

> *I think it's kind of realistic, but I haven't experienced or heard like from my kids or my family and my friends, I never heard this sharing the high-dose painkiller opioid in some, this kind of things. So, I will be neutral. I don't say it's realistic or not realistic.* [Parent 188]

Characters

Parents responded positively to the game's characters. Parents' positive impressions of the characters were mentioned 166 times, whereas negative impressions of characters were noted only 38 times. Characters were described as cute, realistic, and sincere in their interactions. Some participants mentioned that the use of cartoon characters or animation-style graphics may be better suited for younger adolescents rather than older teenagers. Fifteen (22%) participants noted a preference for animal characters, while 4 (6%) participants preferred human characters. Participants appreciated that characters were gender-inclusive with neutral names and presentation. According to parents, animal characters contributed to this inclusivity.

> *And so, I think that it was, it was a good, you know, they had the things that the kids could find in common with them, you know. Common things in terms of like, for instance, being anxious about things at school, you know, and things like that, it was, it was a good thing. I liked the characters.* [Parent 150]

Graphics

Parents stated that the graphics were cute and interesting but may have been designed for younger children. Only 4 (6%) participants stated that the game graphics were outdated. Participants also stated that the graphics may be basic for adolescents who often play games with advanced graphics.

> *In comparison to games and apps that kids use right now. They're pretty, it was pretty basic. And the, the*

> *animals were- if you're looking for teenagers or adolescents- a bit juvenile.* [Parent 165]

Navigation

Some parents (n=38, 57%), had difficulties with navigation, especially in level 1. Eleven (16%) participants sought more in-game directions for navigation while playing and suggested that keyboard controls (W, A, S, D keys) were difficult to use. For most parents, the game navigation became easier as the participants continued to play the game. Some participants (n=10, 15%), suggested gameplay may be more intuitive for a child rather than a parent.

> *Like, I wasn't sure I was supposed to walk around and look for things, or if it was going to read me something, or if I was just waiting for things. So, I think at least at a time in the beginning, like, figuring that part out. And then when it had me redo a level a couple of times because I did something wrong. So, I knew I was looking for a key in the beginning, but I couldn't walk around the room and look for it.* [Parent 183]

> *It was a little hard to know how to use it at the very beginning because there weren't a lot of instructions, I wasn't sure exactly what I was supposed to do when it started. But I caught on after the end of the, by the end of the 1st scene.* [Parent 118]

Pace

Participants mentioned that the game had a slow pace with opportunities to repeat the game scene when the wrong action was selected. Time burden was reported due to the amount of dialogue the participant had to read throughout the game.

> *There was just too much to read. Instead of like, little blurbs, it was like, big passages to read. I mean, as far as getting people's attention, unfortunately, I felt like it was more like, I was reading it, but if I wasn't doing a survey for it, I'd just be clicking, clicking, like, waiting for it to ask me a question. That way I can answer it and move on to the next subject.* [Parent 155]

Theme 3: Educational Purpose of Game

Overview

Many participants expressed positive opinions about using a video game to educate their children on opioid medication safety. The parents reported that game-based learning would help their children remain engaged with the content. They also noted that the game would be a beneficial way for children to share what they learned with friends.

Perceived Main Idea of Game

When asked what they perceived to be the main educational point of the game, 23 (34%) participants reported the promotion of safe use of opioids and 13 (19%) stated prescription medications in general. Additional perceived goals of the game included education on proper opioid medication storage, which was reported by 9 (13%) participants while 22 (33%) participants reported that the overall goal of the game was medication storage in general. Encouragement to avoid sharing prescription medications was cited by 33 (49%) participants, and discussion of proper medication disposal techniques for opioids was suggested by 10 (15%) participants or medications overall was stated by 10 (15%). A portion of 17 (25%) participants further stated that the game accomplished the goals that they perceived.

> *The main goal of the game was to me, it was educating the public and, and people about, uh, using prescription medicine faithfully. And to me, the, the game did meet that goal. Especially like in that first part getting it, you know, securing it, locking it up. And not taking things that are, that do not have your name on it, that are not for, you. Um, and not offering it to people because you think it may help them. I think the game did- for what I played of the game- I think that did drive that point home.* [Parent 147]

Reading Level

Parents believed that the game's reading level was more appropriate for older adolescents than elementary-aged children.

> *And so, it seemed like it was designed for much younger than the characters in it, which was fine, but some of the things they were saying, I don't think the younger kids would be able to read.* [Parent 131]

Target Audience

Participants reported that children of elementary or middle school age would be the primary target audience. Participants thought children 5 to 15 years of age would benefit most from the game but mentioned that the educational points are important for all ages. Dialogue and game scenes were perceived as more appropriate for older teenagers than younger children. Parents stated that their older teens may think the game less engaging due to its slow pace. However, parents reported that their children would learn from the game and gain confidence in safe prescription opioid behaviors.

> *I think that it can be valuable and not just the game itself, but […] perhaps the kid and parents could play it together, or the parent could watch the child playing it and it could help fill in any missing pieces or answer questions that the kid might have. I think it's a nice way to introduce the topic for a family discussion in a way that could be more engaging and that could hold the kid's interest a bit more than just straight laying it out there.* [Parent 137]

> *I definitely would recommend it to others because it obviously is extremely important and needs to be, it needs to be brought up to anyone who will listen. But I would recommend it to a younger crowd, I think.* [Parent 143]

Participant Learning Experiences

Some (n=27, 40%), participants reported that the game confirmed their existing knowledge, while 22 (33%) others reported that the game did not provide novel educational points. Two frequently reported educational outcomes included medication storage recommendations and awareness of medication disposal options. Specifically, participants realized that they do not typically store medications in a locked area and do not have a locked area available in their homes. A substantial number of participants (n=15, 22%), were not aware of available pharmacy medication disposal drop boxes until playing the game. The game also emphasized the importance of parent-to-child medication safety education wherein participants discussed improved awareness of medication safety scenarios, such as when friends of their children visit the home. Parents were also motivated to increase communication about medication safety with their children after playing the game.

> *That opioids should be locked up. That's that got most to me because when, because my children were a little older when I was prescribe[d] codeine and, you know, you just assume they're not going to touch it. And the childproof caps, I didn't lock mine up. But now seeing that I probably should have, because you don't know who else is in your house and can get to your medication.* [Parent 199]

> *I had no idea that there were drop boxes for medicine or that you were supposed to take it back to the pharmacy.* [Parent 169]

Theme 4: Future Use of Game

Overview

Over half of participants (n=39, 58%), stated they would recommend MedSMARxT: Adventures in PharmaCity, and 17 (25%) other participants would provide a conditional recommendation. A small number of 5 (7%) participants mentioned that they would not recommend the game, 1 (1%) participant would conditionally not recommend it, 1 (1%) participant was indifferent, and 2 (3%) participants had mixed recommendations. Two (3%) participants did not provide a recommendation for or against the game.

Suggested Improvements

Improved navigation was cited as a future improvement 39 times. Participants recommended a tutorial, in the beginning, to explain navigation, pop-ups throughout the game to encourage exploring the scene, or adding a hint button. They also endorsed the use of keyboard arrow keys, a computer mouse, or touchscreens over current W, A, S, D keyboard controls.

> *I would have benefited from like, a little simple, like, practice round at the beginning, just a simple like, this is, I mean, this is how you move and how you jump and how you do these things.* [Parent 183]

To increase the pace of the game, participants desired an option to skip over dialogue especially if repeating a game scene. Participants would prefer less text dialogue and more direct questions to prompt user action. Participants recommended the incorporation of social media, live video clips, and customizable characters to increase engagement for older teens.

Participants sought additional educational content, including a scene in the beginning of the game where the main character discusses information and instructions about their medication with a physician or a parent. Participants suggested this scene could include exposure to the medication package insert, a display of warning labels found on the medication bottle, or background information on the character's injury. More education regarding the recognition and treatment of opioid overdose was requested. Participants emphasized the importance of all users being able to see the consequences of wrong actions, even if they choose the correct actions in the game.

> *I would say to ensure that all the scenarios, so, even if you didn't, you know, end up in a particular sort of side quest you still got that information. Um, so maybe creating additional scenarios that so you didn't miss certain information if you answered in a particular way, and you just didn't end up on that diversion.* [Parent 142]

Applications

Specific settings thought to be right for future use include health care settings (physician offices, pharmacies, and dental offices), particularly in waiting rooms and school settings (health classes, drug awareness programs, and use with sports injuries). Participants stated that the game would be effective as a kiosk within a pharmacy or as a mobile game linked via a QR code in a health care setting.

> *I can see this being a game for again, in the clinic, or a doctor's office, meant to be educational or in school. I'm not sure if anyone would, like, download this game to play it just to just to play a game about learning about opioids or, you know, how to use them correctly and stuff like that, but I could definitely see this being a way to educate kids where it doesn't seem like it's a chore for them where they can use it to have fun and play a game and learn something at the same time.* [Parent 167]

Discussion

Principal Findings

Parental feedback demonstrates the acceptability and appropriateness of MedSMARxT: Adventures in PharmaCity as evaluated through parent perceptions of game design, navigation, educational purpose, and future game applications. The study findings indicate that most parents support the use of educational games to teach adolescents about opioid medication safety, emphasizing that this approach is more appealing and engaging for youths as compared to traditional learning methods. Moreover, many parents stated that they would recommend the game to others, showing its appropriateness in engaging parents and garnering their support in using the game to educate their children. Despite being a serious game directed toward use by youths, MedSMARxT: Adventures in PharmaCity also taught parents of adolescents important opioid medication safety practices, including safe storage and disposal.

Comparison to Prior Work

Video games, specifically serious games, demonstrate the potential to improve key behavioral intentions and knowledge related to positive outcomes in various health conditions [31-33]. MedSMARxT is the first serious game to address opioid safety in adolescents [14]. As such, it is critical that the game be evaluated with relevant stakeholders to ensure key quality criteria [34-36]. Prior research has elucidated some key quality criteria in the development of serious games including the salience of the overarching goal of the game, appropriateness of the game content, enjoyment, and acceptable media presentation [37]. In order to best tailor the game to the target players, the study team has rigorously evaluated the game among groups of stakeholders. For example, the study team has conducted research with pharmacists to validate the educational content and their perceptions of using the game in pharmacies when opioid medications are dispensed. Pharmacists reported that the information presented in the MedSMARxT is accurate and age-appropriate while potentially useful for populations aside from adolescents such as parents or older adults [38].

Previous work by the study team has focused on the development of MedSMARxT wherein community-based participatory research was used to elucidate adolescent knowledge gaps and preferences for education on medication safety [39]. Adolescents most frequently reported web searches, parents, health care providers, and web-based videos as resources for medication safety information, which highlights the integral position of parents and health care professionals such as pharmacists in ensuring appropriate and correct education for adolescents [39]. In prior studies on adolescent receptiveness to using educational games to improve medication knowledge, nearly 80% of adolescent participants indicated they would be receptive to using an educational game [40]. Concordantly, this study demonstrates that parents are also receptive to the use of an educational game to educate their adolescents on opioid safety. Moreover, parents of adolescents in this study reported experience with video games at elevated levels (84%). In conjunction with previous studies, this study indicates sufficient receptiveness toward MedSMARxT for families with adolescents.

Existing research also indicates that serious games contain realistic scenarios that engage and motivate participants more than traditional learning approaches [41]. Parents in our study offered positive feedback on the game features including the media presentation (graphics) as well as the characters and individual gameplay levels. Coupled with the correct identification of the game's overarching goal, these findings describe the potential balance of serious and game elements in the MedSMARxT game.

Although the original, intended audience is adolescents, parents likewise reported new learnings. Parents most often reported newfound knowledge about proper disposal and storage. Research has demonstrated the importance of educating patients on safe disposal. When patients are taught the proper method of disposal, they are more likely to dispose of their medications in a safe manner [42,43]. Beyond the use of a serious game to provide education to adolescents, parental involvement in adolescent medication use practices has been a protective factor against prescription drug misuse [27]. Parents can act as useful resources for information about opioid safety and important models of proper opioid use when they themselves have the requisite education. Recognizing the vital role that the family plays in the development of medication use behaviors, the National Institutes of Health [44] recommends family-based prevention programs as an effective means to reduce rates of opioid misuse among youths. Parental exposure to topics their children are learning about can promote discussions foundational to future safe medication use behaviors. Parent responses suggest that this intervention could foster family conversations around opioid and prescription medication safety by providing parents with an educational resource for both them and their children.

This study of MedSMARxT: Adventures in PharmaCity showed a perceived educational benefit for adolescents and a reported gain in parental exposure to opioid medication safety topics. Parents were able to explore realistic scenarios that their child may experience. For example, through playing level 1, parents realized that proper opioid storage in the home is not only important for their child but also for their children's friends who may visit the home.

Future Directions

While overall perceptions of the MedSMARxT game were positive, findings from this study suggest further improvements including a navigation tutorial, an option to skip through dialogue when repeating scenes, and explicit hints or objectives. While iterative improvement of the game itself is vital to future uptake, implementation effectiveness studies are integral to determining the best location and means for implementing this novel educational technology. Future studies will work to evaluate the effectiveness of MedSMARxT in different health care and non-health care settings to determine fit and implementation.

Strengths and Limitations

Strengths of this study include sampling a significant parent population from across the United States, which provided a representation of many parenting opinions and styles. Second, the use of open-ended questions during the interview provided participants ample opportunity to discuss all aspects of MedSMARxT: Adventures in PharmaCity that they perceived were important. Third, analysis was carried out by 2 research team members for triangulation (GAN and LLS), guided by the principal investigator for reflexivity (OA), and validated through peer debriefing and an audit trail to support trustworthiness in terms of credibility, transferability, dependability, and confirmability.

There are limitations to this study. The first is that of self-selection bias in this sample. While this study uses a considerably large sample size for a qualitative study, parents' self-selected participation could be present in terms of those who favor the use of educational games being more likely to participate. Second, there are limitations surrounding demographic homogeneity in this sample. The format of study activities would exclude families without access to high-quality internet or those without a computer in the home. Therefore, our study sample, while a national sample, is homogenous in terms of socioeconomic status and education level. Hence, findings of acceptability may be less generalizable to those in more difficult socioeconomic situations and those who discontinued education after high school. Recruitment was carried out across multiple streams (Qualtrics panels, social media, listserves, snowball) across a few months in order to create a sample that was as robust as possible. The study team used practices such as investigator triangulation, peer debriefing, and reflexivity to improve the trustworthiness of the data collected.

Third, social desirability bias could play a role in the positive perceptions of the parents. It is possible that when asked about their perceptions, parents were more likely to offer a positive response than a negative response. To account for this potential, the interview guide was designed and piloted to ensure neutrality in questions and prompts. Future work could use anonymous surveys to remove the researcher from data collection and decrease social desirability. The findings of this study are trustworthy given that questions were tailored to touch on multiple parts of the intervention and questions regarding potentially threatening topics were not used.

Conclusions

The creation and use of serious educational games to teach adolescents about opioid medication safety could be an effective approach to improving youths' knowledge of opioid prescription safety. This study investigated parent perceptions of MedSMARxT: Adventures in PharmaCity and found that parents believe this game would be beneficial for youths. MedSMARxT: Adventures in PharmaCity could be used in various non-health care and health care settings in the future to educate adolescents and inspire meaningful parent-adolescent conversations about safe opioid use.

Acknowledgments

The authors would like to thank the CRoME Lab researchers who contributed to data collection. The authors would also like to thank Tyler McCarthy for reviewing and editing this study. No part of this paper used generative artificial intelligence technology. This study was supported by the University of Wisconsin-Madison Prevention Research Center Small Grant Award. The University of Wisconsin-Madison Prevention Research Center is a member of the Prevention Research Centers Program. It is supported by the Centers for Disease Control and Prevention cooperative agreement number 1U48DP006383. The study was also supported by KL2 grant KL2 TR002374-03 and grant UL1TR002373 to UW ICTR by the Clinical and Translational Science Award program, through the NIH National Center for Advancing Translational Sciences. Abstract

Background: Promoting healthy eating in children is key to preventing chronic diseases, and vegetable consumption is notably lower than recommended in this population. Among the interventions tested, gamification has shown promise in promoting familiarization, increasing knowledge, and potentially increasing vegetable intake.

Objective: This pilot study aimed first to translate the digital game “Veggies4myHeart” into French and to assess its influence on young children’s preferences and willingness to taste vegetables when combined with repeated tasting and education. We also aimed to investigate the acceptability and applicability of the game in 2 classrooms.

Methods: During 5 consecutive weekly sessions, children from 2 elementary classes played the digital game consisting of 5 mini games on different vegetables (lettuce, carrot, red cabbage, cucumber, and tomato) in pairs for 10-15 minutes. In addition, they discussed one of the vegetables and tasted the 5 vegetables in each session. Pretest and posttest food preferences and willingness to taste the vegetables were compared. Teachers participated in a semistructured interview.

Results: A total of 45 children aged 5 to 6 years tested the French version of the digital game. The children’s declared food preferences were already high for carrot, cucumber, and tomato, with scores higher than 4 out of a maximum of 5. The scores did not change significantly after the intervention, except for red cabbage (pretest: mean 2.52, SD 1.49; posttest: mean 3.29, SD 1.67; *P*=.006) and a composite score (pretest: mean 3.76, SD 1.06; posttest: mean 4.05, SD 1.03; *P*=.001). Before the intervention, 18 (44%), 30 (73%), 16 (39%), 29 (71%), and 26 (63%) children out of 41 were willing to taste lettuce, carrot, red cabbage, cucumber, and tomato, respectively. After the intervention, no significant statistical differences were observed, with 23 (51%), 36 (80%), 24 (53%), 33 (73%), and 29 (64%) children out of 45 willing to taste lettuce, carrot, red cabbage, cucumber, and tomato, respectively. Teachers supported this tool combined with repeated tasting and education and highlighted facilitators and barriers that should be anticipated to improve implementation in schools.

Conclusions: In this study, we translated an existing digital game applicable and acceptable to both children and teachers. A larger study is warranted to confirm the effectiveness of interventions using the digital game to promote vegetable preference, willingness to taste, and intake.

Introduction

Vegetable Consumption in Children

Healthy eating is recognized as a cornerstone of health promotion [1], yet there is a persistent gap that exists between dietary recommendations and actual intake [2]. This is particularly true for children, and especially with regard to fruit and vegetable consumption [3-5]. Establishing healthy eating habits during infancy and childhood is a widely shared public health goal [6], and the promotion of fruits and vegetables is often at the heart of such programs [7]. In fact, fruit and vegetable consumption is a protective factor for many health conditions [8]; however, children often begin to reject these foods during the developmental phase of neophobia [9]. Food neophobia is defined as the fear of eating new foods and appears around the age of 2 years, with a paroxysm between the ages of 2 and 6 years [10]. During this time, children tend to reject any new food or food presented in a novel way; this is especially true for vegetables, which is often explained by their low energy density and strong taste [10]. Evidence shows that the effects of food neophobia can be limited by increasing familiarity with the food and promoting exposure, associative learning, and tasting [11,12].

Serious Games to Promote Vegetable Intake

Gamification is an interesting new approach to engage children with vegetables in an attractive way. Moreover, this tool may be particularly suitable for highly neophobic children, as it works through visual exposure [13]. Some traditional games, such as memory or board games, have been shown to have a positive influence on eating behaviors [14,15], and the ability of digital games to improve health and food habits has also been tested, taking advantage of their ability to promote interactivity, provide fun, and attract attention [16]. The "Veggies4myHeart" digital game was developed in Portugal and consists of 5 mini games, each featuring a vegetable superhero. It was successfully tested with children aged 3-6 years and, when combined with exposure through vegetable tasting, led to an increase in vegetable consumption [17].

Challenges in Developing and Using Serious Games

Developing digital games is time-consuming and resource-intensive [16]. Using existing games is a solution to save resources; however, whether cultural specificities exist should be clarified before translating and using such games on a large scale. The question of how to use digital games more effectively also remains open. A digital game can be used as a stand-alone tool or integrated into a larger program and combined with other features.

Objectives

The aim of this pilot study was to translate the digital game Veggies4myHeart into French and to assess its influence on the preferences and willingness to taste vegetables of young Swiss children in combination with repeated tasting and education. As a second objective, we investigated teachers' opinions about the game and its acceptability and applicability in two classrooms.

Methods

Participants

This pilot study involved 45 children from two classes of an elementary school in the French-speaking part of Switzerland and their teachers. The children were between 5 and 6 years old and included 19 boys and 26 girls. The children from the two classes received the same intervention. The two teachers volunteered to participate in the study.

Ethical Considerations

Parents were informed about the intervention and could request that their child not participate in the study. No personal data were collected, so this pilot study did not fall under the Swiss Federal Human Research Act. However, it was submitted to and approved by the Service of Research in Education in Geneva, Switzerland (research number 584).

Veggies4myHeart Digital Game and Translation

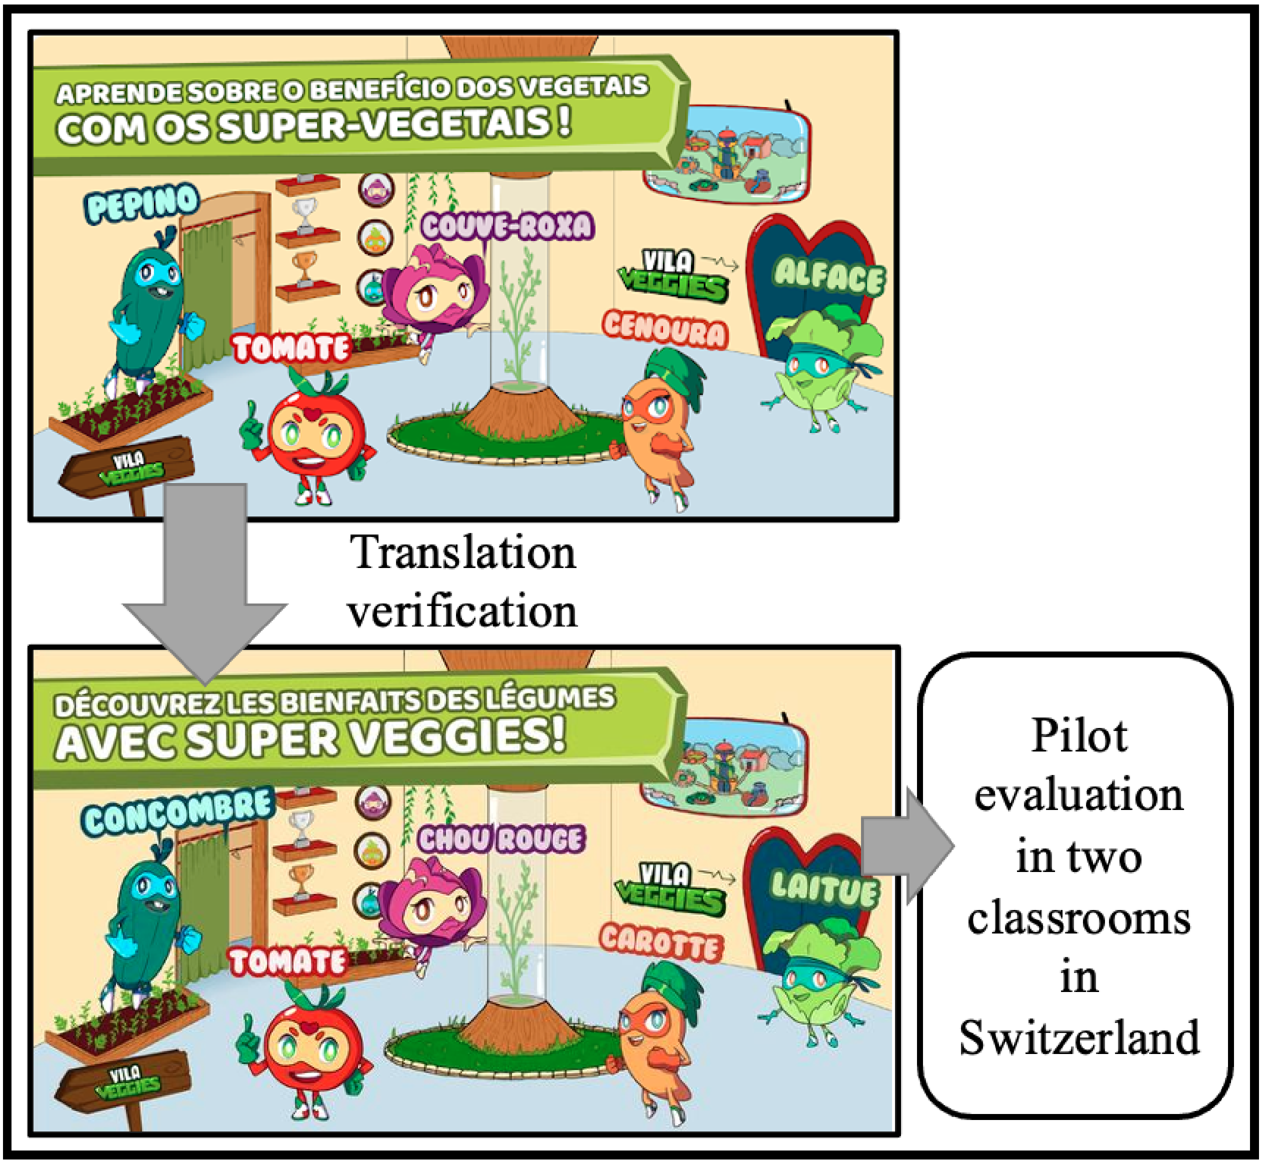
The Veggies4myHeart digital game was developed by a team of researchers at the Polytechnic of Leiria in Portugal [17]. The digital game was designed for preschool children aged 3-6 years and consists of 5 mini games, each related to one of the following vegetables: carrot, tomato, lettuce, cucumber, and red cabbage. For each vegetable, an introduction presents the vegetable, its characteristics, and health benefits and explains the goal of the task in the game.

The game setting is a farm. Children, through the vegetable superheroes, are involved in watering the fields, protecting the vegetables from pests, or picking the vegetables. In each mini game, children must race against the clock to collect as many points as possible, winning medallions at each step. Children can also customize their superheroes.

The Veggies4myHeart video game was developed to support the personal factors of motivation and knowledge that are necessary to improve the targeted behavior. Indeed, in a model based on social cognitive theory, Reynolds et al [18] show how environmental factors (availability, modeling, and nutrition education) and personal factors of motivation and knowledge can improve the specific behavior of fruit and vegetable consumption in young children. Specifically, the game enhances the following important determinants of vegetable consumption: (1) perceived self-efficacy through positive experiences with vegetables, persuasion, and by convincing the children of their ability to eat vegetables in different situations; (2) outcome expectations through age-appropriate persuasive communication and game stories that emphasize the positive effects of eating vegetables; and (3) food preferences by increasing familiarity with the vegetables. Knowledge about vegetables is also increased through the various messages delivered throughout the game. In addition, several known mechanisms involved in learning to eat vegetables underlie our intervention [19]. For example, the digital game allows nontaste exposure to vegetables. Previous studies have shown that it is possible to increase familiarity in the absence of real food through picture books, storybooks, and digital media [13,20]. Associating images of vegetables with a narrative or a character enhances the playful element of the learning experience and encourages a willingness to taste by enabling a positive affective experience during exposure [19]. Rewards, ranging from social praise to small nonfood gifts such as stickers, are another well-known strategy to increase learning and have been used to facilitate children's intake of fruits and vegetables and promote liking [21]. In digital games such as Veggies4myHeart, rewards are used differently: as participants progress through the game, they earn achievements, prizes, or rewards that encourage learning and increase extrinsic motivation to play the game [22,23].

The digital game was originally developed in Portuguese. A Portuguese French teacher translated the scripts into French, a Swiss researcher verified the French script, and two children recorded the texts in French, as illustrated in Figure 1.

Figure 1. Steps to translate Veggies4myHeart from Portuguese into French and to test it in Switzerland.



Procedures of the 5 Sessions

The research team visited each class for the intervention once a week for 5 consecutive weeks. Each session focused on one vegetable: carrot, red cabbage, lettuce, tomato, and then cucumber. The study took place in May and June 2021.

At the beginning of each session, the dietitian introduced the vegetable of the day and asked the children if they knew how to prepare or cook it. The characteristics and benefits of the vegetable were discussed. This short educational session was designed to complement the digital game.

The children then got into pairs and played the Veggies4myHeart digital game described below on an iPad-type tablet. Each child played the mini game related to the vegetable of the day for 10-15 minutes.

During each session, children were invited to taste the 5 vegetables presented raw and plain in small pieces and the investigator recorded the types of vegetables tasted. Repeated exposure was included in the intervention because it is a very simple yet powerful strategy to promote vegetable intake, as shown in a meta-analysis published in 2018 [24]. The authors found that intake was positively associated with the amount of taste exposure and was greater for unfamiliar vegetables and when they were presented in plain form [24]. Repeated exposure allows children to increase their familiarity with unknown vegetables and to learn about their safety, resulting in increased acceptance and liking [19].

At the end of the intervention, children received a booklet with recipes using the 5 vegetables in the game and information for parents on how to download the game for free if they wished. Throughout the whole process, the children were unaware of the objectives of the study.

Pre-Evaluation and Postevaluation of Preferences and Willingness to Taste

Two identical standardized assessment sessions were conducted by a team of dietitians. These sessions took place 1 week before the first session and 1 week after the last session. The assessment included an evaluation of the preferences of 10 food items, including 8 fruits and vegetables, and an assessment of the willingness to taste the 5 vegetables in the game as a way of evaluating behavioral neophobia [25].

To evaluate preferences, each child was asked to indicate his or her preference for each of the 10 photographed foods using a visual rating scale of 5 smileys (5: like it a lot; 4: rather like it; 3: neither like or dislike it; 2: rather dislike it; 1: dislike it a lot). The document used for this evaluation is provided in Multimedia Appendix 1. To assess the willingness to taste, each child was invited to taste the 5 vegetables from the digital game (ie, carrot, tomato, lettuce, cucumber, and red cabbage). The 5 vegetables were cut into small pieces and presented simultaneously on a table in front of the child, with a similar level of accessibility. The number of different vegetables tasted was counted.

Throughout the assessment, the children were assessed individually, and the dietitian remained neutral throughout the assessment (no help, praise, or encouragement). With the help of the teachers, a code corresponding to the child's number on the class list was used to identify the children. Thus, the investigators did not collect any personal data on the children.

Assessment of Acceptability and Applicability

To answer our second objective, the investigators observed and took notes on the process of each session. After the 5 sessions, they collected the teachers' opinions on the usefulness and acceptability of the digital game, potential adaptations, and the facilitators and barriers to its use in schools. Both teachers participated in a common semistructured interview based on open-ended questions (Multimedia Appendix 2). The interview was recorded and the teachers signed a consent form.

Data Analysis

Descriptive statistics are reported as means and SD, medians and IQR, frequencies, and percentages. Pre-post comparisons were performed using the Wilcoxon test for paired samples due to a lack of normal distribution. $P<.05$ was considered statistically significant. All analyses were performed using SPSS Statistics 27 (IBM Corp).

Regarding the teacher interviews, one researcher analyzed the data using a qualitative descriptive approach based on notes and recordings. The researcher identified dominant and relevant themes associated with the data and highlighted conceptual similarities and differences between the two teachers. Two other researchers reviewed the analysis and checked the themes for reliability. Themes were then synthesized, classified, and analyzed based on the interview grid and predefined research questions.

Results

Translation and Implementation

The Veggies4myHeart digital game, originally developed and accessible in Portuguese, was successfully translated into French. The narrative of the game and the messages about the 5 vegetables did not need to be changed, and no cultural adaptation was required. The main adaptation in game use related to the seasons in which the 5 vegetables are grown locally in Switzerland. Children and teachers did not report any problem with comprehension. The intervention was implemented as planned; however, a 45-minute period was necessary when taking into account the time needed for the children to settle into the classroom, wash their hands, and socialize with the dietitian.

Pre-Evaluation and Postevaluation of Preferences and Willingness to Taste

The pretest evaluation highlighted that some vegetables in the game already scored high in the children's food preferences, especially carrots. On a scale of 1-5 (5 being "I like it a lot"), the mean rating was >4 for carrots, cucumber, and tomato, as well as for apple, which was not part of the video game. The liking of carrots further improved by another 7%, but the greatest increase in preference was for red cabbage, which increased significantly by 31% to a mean score of 3.29 (SD 1.67; $P=.006$), as shown in Table 1. When combining the scores of the 5 vegetables in the game into a composite score, the children's liking improved post intervention. The preference for fruits and vegetables not present in the game did not change significantly in pre-post comparisons. Before the intervention, the mean score was 3.88 (SD 1.54) for apricots, 2.12 (SD 1.48) for fennel, and 4.31 (SD 1.35) for apples, and after the intervention, the mean scores were 4.09 (SD 1.31), 2.11 (SD 1.56), and 4.51 (SD 1.12), respectively.

A similar progression was seen in the willingness to taste task, with 24 (53%) children willing to taste red cabbage after the intervention compared to 16 (39%) before. However, none of the differences in willingness to taste were statistically significant (Table 2).

Table 1. Preintervention and postintervention mean score of preference of the five vegetables in the video game.[a]

	Pretest (n=42), mean (SD)	Posttest (n=45), mean (SD)	*P* value[b]
Lettuce	3.90 (1.46)	4.02 (1.47)	.37
Carrot	4.19 (1.40)	4.49 (0.99)	.16
Red cabbage	2.52 (1.49)	3.29 (1.67)	.006
Cucumber	4.10 (1.54)	4.31 (1.40)	.12
Tomato	4.07 (1.50)	4.13 (1.50)	.12
Composite score	3.76 (1.06)	4.05 (1.03)	.001

[a]Maximum score=5.

Table 2. Number and proportion of children who tasted each vegetable before and after the intervention.

	Pretest (n=41), n (%)	Posttest (n=45), n (%)	*P* value[a]
Lettuce	18 (44)	23 (51)	.25
Carrot	30 (73)	36 (80)	.23
Red cabbage	16 (39)	24 (53)	.09
Cucumber	29 (71)	33 (73)	.39
Tomato	26 (63)	29 (64)	.46

[a]Wilcoxon test for paired samples.

Teachers' Opinion on Acceptability and Applicability

Two teachers commented on the usefulness and acceptability of the digital game, the potential adaptations needed, and the facilitators and barriers to its use in schools.

Both teachers rated the game very positively and found it appropriate for children aged 4-6 years. They observed that the children were very interested and engaged in the activity. The teachers appreciated the progressive nature of the game, which allowed the children to start with easy levels and then move on to more complex games. In the teachers' view, the game helped to develop knowledge of the names of vegetables and familiarity with them. By remembering what they had to do in the game, the children were able to remember some functions of the vegetables (eg, watering the garden as an illustration of hydration).

The teachers appreciated that the children played in pairs, as this favored interesting interactions between the children. The initial 15 minutes of play was felt to be too long; 10 minutes per child was sufficient for the final sessions. In addition to the game, the teachers felt it was important to offer a tasting and a discussion about the different ways of consuming the vegetable in each session to give a concrete aspect to the activity.

To promote and facilitate the integration of the information, the teachers recommended systematically repeating the messages of the game during the conclusion of the activity following the game sequence. They also suggested developing visual material, such as pictograms for each vegetable or a laminated map of the game to facilitate navigation in the game.

Regarding the implementation of the activity in the classroom, the teachers stated that they could manage the sequence on their own, but this would require having tablets readily available.

Discussion

Principal Findings

In this study, a Portuguese digital game consisting of 5 mini games about vegetables was successfully translated into French and tested in two classrooms with children aged 5-6 years. No cultural adaptation was necessary, and the children played the digital game without any difficulties. The teachers confirmed their interest and the feasibility of integrating such a game into their teaching. In addition to the game, the children received information about the vegetables in the game and had the opportunity to taste them repeatedly. However, although the pre-post comparison of preferences and willingness to taste vegetables showed some promising trends, few differences were statistically significant.

Comparison With Prior Work

In the literature, eHealth interventions to promote fruit and vegetable intake consistently produce small but significant improvements. In a meta-analysis that included 19 studies (only 4 of which were in children), all showed a small effect size favoring eHealth interventions [26]. Tailored interventions and those using at least 7 behavior change techniques were the most effective [26]. Given the many factors that influence vegetable consumption, it is expected that no single tool or strategy will work for all children. Multicomponent interventions, on the other hand, combine several techniques, increasing the likelihood that all children will benefit from one strategy or another [19]. Interestingly, brief digital interventions can already be effective, although repeated exposure strengthens the effects [27]. The first study to test the Veggies4myHeart video game was conducted in Portugal. In a preschool, the video game combined with repeated tasting was compared with the use of a storybook and repeated tasting with or without sticker rewards and a control group [17]. After the intervention and at a 6-month follow-up, children in all groups, including the control group, had increased their vegetable consumption. In another study conducted in Taiwan with children aged 5-6 years, a 4-week intervention based on a computer game called "Healthy Rat King" resulted in increased nutritional knowledge among participants, but no differences in junk food consumption were observed compared to the control group [28]. Using a mobile app based on repeated visual exposure, modeling, and rewards, Farrow et al [29] showed an increase in the consumption and liking of vegetables displayed in the app compared to control group. Digital games raise a lot of interest and expectations to promote healthy eating in children, but studies evaluating them, including ours, often lack sufficient sample sizes and appropriate designs to demonstrate their effectiveness and to describe the mechanisms involved [30]. In addition, developing a digital game is expensive and requires a multidisciplinary team of experienced and skilled members [16]; therefore, to conserve resources, translating existing games is a rational and attractive option. In a previous study, an American digital game designed to reduce the risk of obesity and type 2 diabetes was translated and culturally adapted for Hong Kong Chinese children. As in our study, their evaluation, based on a survey and individual interviews, confirmed the acceptability and applicability of the game in the new context [31,32].

Digital Games as Prevention Tools

Serious games expand the range of learning tools available to promote balanced nutrition. We know that, in addition to experiential learning, playful activities enhance children's learning. Digital games appear to be an attractive complementary tool to promote vegetable intake while maintaining a balance between education and play and enjoyment, as an overemphasis on education risks reducing learning [16,19]. Indeed, both enjoyment and user experience have been shown to be positively correlated with learning, as measured by increased knowledge in children [33].

In addition to the game itself, implementation is a critical consideration for effective health promotion interventions. In this study, dietitians implemented the intervention. To scale up and sustain this type of intervention, teachers should be able to implement it by themselves. Following our experience, the two teachers confirmed that they thought the digital game could be used as an additional learning tool, as long as they had support for the logistical aspects, for example, from the school administration. In this respect, our game is easily accessible as a free application on common platforms. To further support teachers, some additional material would be useful, such as a teacher's guide with background information on the overall benefits of vegetables and the specifics of each vegetable, prompts and visuals for class discussions on each vegetable, and recipes. Because the Veggies4myHeart game is freely available, children can continue to play the game at home, potentially maintaining or increasing the impact of the intervention.

Strengths and Limitations

Despite the encouraging results, this pilot study has several limitations. First, the sample size was small and the study lacked a control group to isolate the effects of the intervention. Second, the design did not allow us to analyze the effect of the digital game separately from the effects of the discussions and tastings that were conducted concurrently, nor to identify which game elements were the more effective. Third, we did not measure the children's eating traits, such as fussiness. These factors should be taken into consideration in future analyses. However, based on a quantitative and qualitative evaluation, this study provides useful information for the development and implementation of future interventions that include a digital game to promote vegetable consumption in young children.

Future Directions

Future studies should include a larger sample size and a control group, ideally designed with multiple arms to allow a comparison between elements of combined interventions. Moreover, future samples should include children who do not especially like the vegetables to avoid or limit the ceiling effects observed in our study. Could digital games support food literacy through the development of functional and relational skills? This would be interesting to assess, as a digital game may promote basic nutrition knowledge and a healthy and positive relationship with food and encourage the experience of new and different foods, which are all important elements of food literacy [34]. More generally, larger studies including greater sample sizes are needed to assess the actual impact of digital games and to reach statistical significance.

Conclusions

Digital games are a useful and engaging tool for promoting vegetables to young children. In this study, an existing video game was translated into French and paired with repeated tasting and education to combine multiple strategies and increase the chance of reaching every child. Our experience shows that the digital game was easy for teachers to use in younger grades, but the logistical aspects should be very well prepared. Pre-post comparisons of preferences and willingness to taste vegetables showed some promising trends; however, confirmation with larger samples is warranted.

Using existing games and collaborating to translate them is a promising way to maximize development investments and increase the use and reach of such games. Future games should focus on unfamiliar vegetables and include in-game progression.

Acknowledgments

This study was supported by a grant, “Seed money for joint Swiss-Portuguese academic projects,” from the HES-SO University of Applied Sciences Western Switzerland and the Portuguese Polytechnics Coordinating Council. ML was supported by a PhD scholarship from Fundação para a Ciência e Tecnologia (2021.07673.BD). This work was supported by Portuguese national funds provided by Fundação para a Ciência e Tecnologia (FCT) (UI/05704/2020). MPG was funded by CEECINST/00051/2018.

We thank the two teachers and their students who participated in the study, as well as their school director who supported their involvement. We also thank Helena Frontini for her help translating the scripts of the digital game, as well as the 3 children who recorded them, Mathilde, Dinis, and Tyler. In Geneva, special thanks to Sara Hernandez Seco and Flavia Negro for their participation in intervention implementation and data collection, and to Erkal Altun and Oscar Martinez for their informatic and logistical support.

Data Availability

Abstract

Background: The increasing number of older adults with mental, behavioral, and memory challenges presents significant public health concerns. Reminiscence is one type of nonpharmacological intervention that can effectively evoke memories, stimulate mental activities, and improve psychological well-being in older adults through a series of discussions on previous experiences. Fully immersive virtual reality (FIVR) may be a useful tool for reminiscence interventions because it uses realistic virtual environments connected to a person's significant past stories.

Objective: This review aims to examine empirical evidence regarding the application of FIVR in reminiscence interventions, its usability and acceptability, and its effectiveness in assisting the intervention to achieve optimal outcomes.

Methods: We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) approach for scoping reviews. The PubMed, PsycINFO, Embase, CINAHL, Web of Science, ACM, and IEEE Xplore electronic databases were used for the search. We included peer-reviewed studies that used FIVR as an assistive tool for reminiscence interventions; were published between January 1, 2000, and August 1, 2022; reported empirical research; involved older adults as participants; and addressed health- and behavior-related outcomes or the feasibility and usability of FIVR. We used Endnote X9 to organize the search results and Microsoft Excel for data extraction and synthesis.

Results: Of the 806 articles collected from the databases and other resources, 11 were identified. Most of the studies involved participants aged between 70 and 90 years. Only 1 study did not involve those with cognitive impairments, whereas 3 specifically targeted people living with dementia. The results indicated that FIVR reminiscence interventions enhanced engagement and reduced fatigue. Although some studies have observed positive effects on anxiety, apathy, depression, cognitive functions, and caregiver burden reduction, these findings were inconsistent across other research. In addition, FIVR showed overall usability and acceptability with manageable side effects among older adults across various health conditions during reminiscence sessions. However, 1 study reported adverse feelings among participants, triggered by unpleasant memories evoked by the virtual reality content.

Conclusions: The role of FIVR in reminiscence interventions remains nascent, with limited studies evaluating its impacts on older adults. Many of the reviewed studies had notable limitations: small sample sizes, absence of rigorous research design, limited assessment of long-term effects, lack of measures for health and behavior outcomes, and quality of life. Beyond these limitations, this review identified a list of future research directions in 6 categories. On the basis of the review findings, we provide practical recommendations to enhance FIVR reminiscence interventions, covering topics such as virtual reality content, device choice, intervention types, and the role and responsibility of facilitators.

Introduction

Background

In recent years, there has been a surge in groundbreaking technologies and their applications in transforming care, therapies, treatments, and health prevention for older adults. Fully immersive virtual reality (FIVR) is one among these rapidly evolving technologies applied in diverse interventions, including poststroke rehabilitation [1], cognitive training for people with neurodegenerative diseases [2], mobility and balance training [3], and the reduction of depression [4]. This paper examines the application of FIVR in reminiscence interventions through a scoping literature review, with a particular focus on people living with dementia or mild cognitive impairments.

Reminiscence Interventions

Reminiscence intervention is a type of nonpharmacological therapy [5] that was developed in the 1960s and has gained popularity since the 1980s [6]. Reminiscence is an act of recalling or retelling past experiences or facts [7]. As an early advocate of this technique, Butler [8] argued that reminiscence was an older person's natural adaptive response to late-life developmental crises, with thoughts related to their approaching death. Used in life review therapy, reminiscence helps an older person reorganize past experiences, settle unresolved issues, bring new meaning to the present life, and better prepare for death [8]. Molinari [9] expanded on the notion proposed by Butler [8] and purported that reminiscence activities could take many forms, including storytelling, autobiography, music, reunions, and scrapbooks. He suggested that reminiscence could be conducted in community or clinical settings, with a person or group of people, by laypersons, or by trained professionals; with structured or unstructured methods; or in a formal or casual format [9]. However, many states in the United States, such as Texas, require counseling therapy to be delivered by licensed professionals [10]; interventions done by family members, friends, and noncertified personnel may be referred to as informal exercises or activities.

Pinquart and Forstmeier [11] and Woods et al [12] identified three main types of reminiscence interventions: (1) simple reminiscence, which involved the recall and sharing of positive memories and stories to increase positive feelings; (2) life review, which was conducted in a structured way with the whole-life story, seeking to integrate both negative and positive memories; and (3) life review therapy, which typically aimed at the reevaluation of negative memories, promoting a more positive view of life.

According to Molinari [9], reminiscence interventions help reshape a person's views of life experiences and stories toward positive and coherent outcomes, focusing on strength, success, and lessons learned. Therefore, reminiscence interventions have been used in diverse settings for various purposes: in dementia and Alzheimer care to lessen behavioral and psychological symptoms and enhance cognitive function, social interaction, self-esteem, and quality of life [12,13]; in end-of-life care, such as hospices and palliative care, to enhance life satisfaction and reduce feelings of regret [14]; in patients with cancer to lower anxiety and depression scales and increase hope, dignity, and quality of life [15]; and in rehabilitation to motivate patients to actively participate in the rehabilitation process, fostering a sense of identity and continuity in their life story [16]. Moreover, a literature review conducted by Shin et al [17] revealed that a reminiscence intervention was effective in improving the quality of life and life satisfaction among community-dwelling older adults with no dementia symptoms.

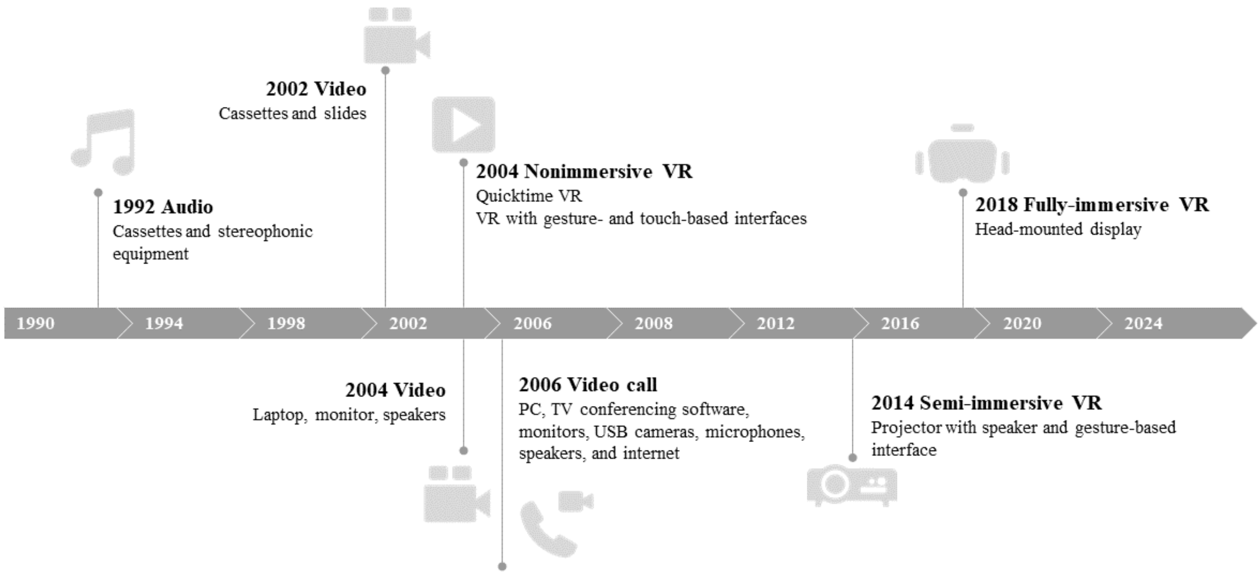
Cues for Reminiscence Interventions

Similar to other psychotherapeutic interventions, a reminiscence session is primarily carried out through conversations, with a provider guiding the person to recall past events, discuss their meanings and impacts, resolve past conflicts, and pave the way for more positive views of the present life. Various media or artifacts that provide visual or audio cues have been applied to stimulate memory and prompt conversations, especially for those with memory problems.

In a literature review, Lazar et al [18] reported that common media for reminiscence interventions included text, videos, photographs, images, music, audio, and personal objects and artifacts such as toys, which were closely related to the person's past experience. The authors also revealed that the technologies to present these media ranged from slide projectors and tape recorders from the 1990s to touchscreen tablets in the early 2010s [19-21]. Moreover, digital technologies have since created more innovative alternatives to aid reminiscence [22-25]. For example, personalized digital memory books and multisensory mobile multimedia environments delivered more content or multiple stimuli in convenient ways [26].

Figure 1 [19-25,27] shows the timeline of different technologies used in reminiscence interventions since 1992. It is worth noting that therapists may have used technologies to aid reminiscence activities in earlier years, but this was not documented in peer-reviewed publications.

Figure 1. Timeline of the technologies applied to reminiscence interventions documented in peer-reviewed publications. VR: virtual reality.



Virtual Reality as an Aid to Reminiscence

Virtual reality (VR) uses computer simulation to provide realistic visual and tactile experiences in a 3D virtual world. VR appears in many forms: (1) nonimmersive, in which a computer or television screen is used to display the content; (2) semi-immersive, in which multiple screens or a Cave Automatic Virtual Environment display present the virtual environment surrounding the participant [28]; and (3) fully immersive, in which the participant wears the VR head-mounted display or haptic devices to be fully immersed in the virtual world. According to Logan [29], VR possesses three main characteristics: (1) interactivity, whereby the user can interact with the virtual world through commands; (2) immersion, whereby the user should have similar authentic feelings, through different sensors, such as those in real environments; and (3) imagination, whereby the user should be able to imagine beyond the virtual world, finding new perspectives or new ways to solve problems.

VR has been applied in a variety of interventions for older adults. D'Cunha et al [30] conducted a literature review on the application of VR and augmented reality in nonpharmacological interventions, examining their effectiveness in promoting psychological health and users' experience. Three types of interventions were tested in the reviewed studies: (1) cognitive or memory training; (2) reminiscence; and (3) therapeutic activities, including physical exercises. The results showed that VR and augmented reality were preferred and well accepted by people living with dementia or mild cognitive impairment and that these technologies helped improve mood, apathy, and cognitive functions. However, some side effects raised concerns about negative feelings after the reminiscence sessions that triggered participants' unpleasant memories. Although immersive VR was used in some studies selected by the authors, most of them were semi-immersive but did not use a head-mounted display that would provide a fully immersive experience.

Although the first head-mounted VR display with 3D graphics and head tracking was invented in the 1960s [31], it was not until the last decade, marked by the introduction of the first consumer-grade VR headset (Oculus Rift) in 2011, that FIVR became more affordable, more technically accessible, and easier to use [32]. FIVR has been popular in a variety of fields such as gaming, education, professional training, medical practice, therapies, and research [33-37]. With its capability to promote interactivity, immersion, and imagination, FIVR may be an excellent aid for reminiscence interventions by stimulating or reactivating the past memories of older adults, especially those living with mild cognitive impairment or dementia.

Reminiscence Interventions for People Living With Dementia or Mild Cognitive Impairments

Population aging has brought about a rapid increase in the number of older adults with cognitive and behavioral problems. Rajan et al [38] estimated that 12.23 million Americans aged ≥65 years experienced mild cognitive impairments in 2020 and that this number would rise to 21.55 million in 2060. The Alzheimer's Association reported that 10% to 15% of people with mild cognitive impairment transitioned to dementia each year [39]. Furthermore, approximately 1 in 9 older adults (10.7%) in the United States had Alzheimer disease, accounting for 60% to 80% of people living with dementia. Cognitive impairment affecting memory, language, orientation, attention, and judgment leads to behavioral and psychological disturbances, dysfunction in activities of daily living, and instrumental activities of daily living [40-42]. Such functional disabilities and behavioral problems have added to caregivers' and family members' burdens and strained health care resources [43].

According to the Alzheimer's Association, pharmacological and nonpharmacological options may be available to treat cognitive impairments, depending on their causes [39]. However, pharmacological treatment options are limited, with only 6 drugs—specifically for Alzheimer disease—currently approved by the US Food and Drug Administration [39]. In addition, there is evidence that pharmacological treatments for behavioral and psychological symptoms of people living with dementia often come with adverse side effects, including an increased risk of falls and fractures, stroke, and even mortality and limited efficacy in symptom management [44]. Nonpharmacological therapies are safer options with manageable side effects for people with cognitive impairments than pharmacological treatments. These therapies can help reduce anxiety, depression, apathy, irritation, and other negative emotions and possibly decrease the need for pain and psychoactive medications by not inducing biological changes [45]. After reviewing the literature, Cammisuli et al [5] categorized nonpharmacological interventions into four main categories: (1) holistic techniques, including reality orientation that helps people living with dementia be aware of who and where they are and what time it is; cognitive stimulation therapy that uses a series of objects, themes, or activities, such as physical games, sounds, food, current affairs, scenes, word association, using money, and number games to stimulate cognitive functioning; and reminiscence; (2) brief psychotherapies, a type of psychodynamic therapy that emphasizes the identity of people living with dementia through a conversation about past experience, with the aim of reducing emotional distress and other behavioral problems; (3) cognitive methods, such as the space retrieval technique, which trains people living with dementia to regain the ability to associate names with human faces or with objects; and (4) alternative strategies, such as music therapy and bright light therapy [5].

As previously noted, Cammisuli et al [5] categorized reminiscence interventions as a holistic technique of nonpharmacological therapy. Evidence has shown that appropriate reminiscence interventions for older adults with cognitive impairment can effectively evoke memories, alleviate anxiety and depression, reduce stress, manage cognitive decline, increase self-esteem, and improve quality of life [11,46,47]. Importantly, these interventions may potentially lower caregivers' burden and stress due to the improvement in their care recipients' psychological, mental, and behavioral health [48], which is significant as the world is experiencing a serious shortage in the nursing workforce.

Research Aims

We found little collective knowledge on how FIVR works in reminiscence interventions. Therefore, this scoping review aimed to assess and synthesize existing evidence regarding the influence and effectiveness of FIVR as an aid in reminiscence interventions. We expected the findings to elucidate potential directions for future research, offer recommendations for practice, and address the critical needs of caring for frail older adults, particularly those living with dementia and mild cognitive impairments.

Methods

Overview

We adopted PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analysis extension for Scoping Reviews) to map the evidence for FIVR-based reminiscence interventions. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) is a minimum set of evidence-based items for reporting in systematic reviews and meta-analyses [49]. The PRISMA-ScR—with 20 essential reporting items and 2 optional items—was created to synthesize evidence and assess the scope of the literature on a topic [50]. The detailed descriptions of the 22 items are reported in Multimedia Appendix 1. Compared with systematic reviews, scoping reviews address a broader research question [51]. They allow researchers to identify the scope of the literature in a certain area, provide a clear indication of the available literature and an overview of its focus, and examine emerging evidence that informs field practice [51]. We adopted the scoping review approach because it perfectly aligns with our study's aims.

Search, Screening, and Selection

We applied the following inclusion and exclusion criteria for article selection: (1) the use of FIVR as an aid for reminiscence interventions; (2) the inclusion of adults aged ≥65 years; (3) reporting on empirical studies; (4) reporting on outcomes related to health and well-being and the feasibility or usability of FIVR; (5) publication in English; and (6) publication in peer-reviewed journals or peer-reviewed conference proceedings between January 1, 2000, and August 1, 2022. Electronic databases—PubMed, PsycINFO, Embase, CINAHL, Web of Science, ACM, and IEEE Xplore—were used for the literature search. The search terms included all possible synonyms and combinations of "Reminiscence Interventions and/or Therapies" (reminiscence, life story, reminisc* therapy*, and memory simulation) and "Virtual Reality" (VR, imagined 3D environment, and simulat* environment).

First, a researcher used a consistent set of keywords to search each database between March and August 2022. The search results were imported and organized using Endnote X9 (Clarivate), a computer reference management program. Second, 2 researchers scanned the titles and subsequently the abstracts of the retrieved articles. They then independently reviewed the full texts, collating all eligible articles. References from these articles were also scrutinized to capture any potentially overlooked information in the initial database search. Subsequently, the researchers deliberated each article in detail, deciding on its inclusion based on predetermined criteria and the study objectives. In case of any disagreements between the 2 researchers, a third researcher was ready to intervene with a final decision. However, this contingency was not triggered.

Data Extraction and Analysis

We continued to use Endnote X9 to manage the selected articles and Microsoft Excel spreadsheets for data extraction. The categories of the data included title, author, year of publication,

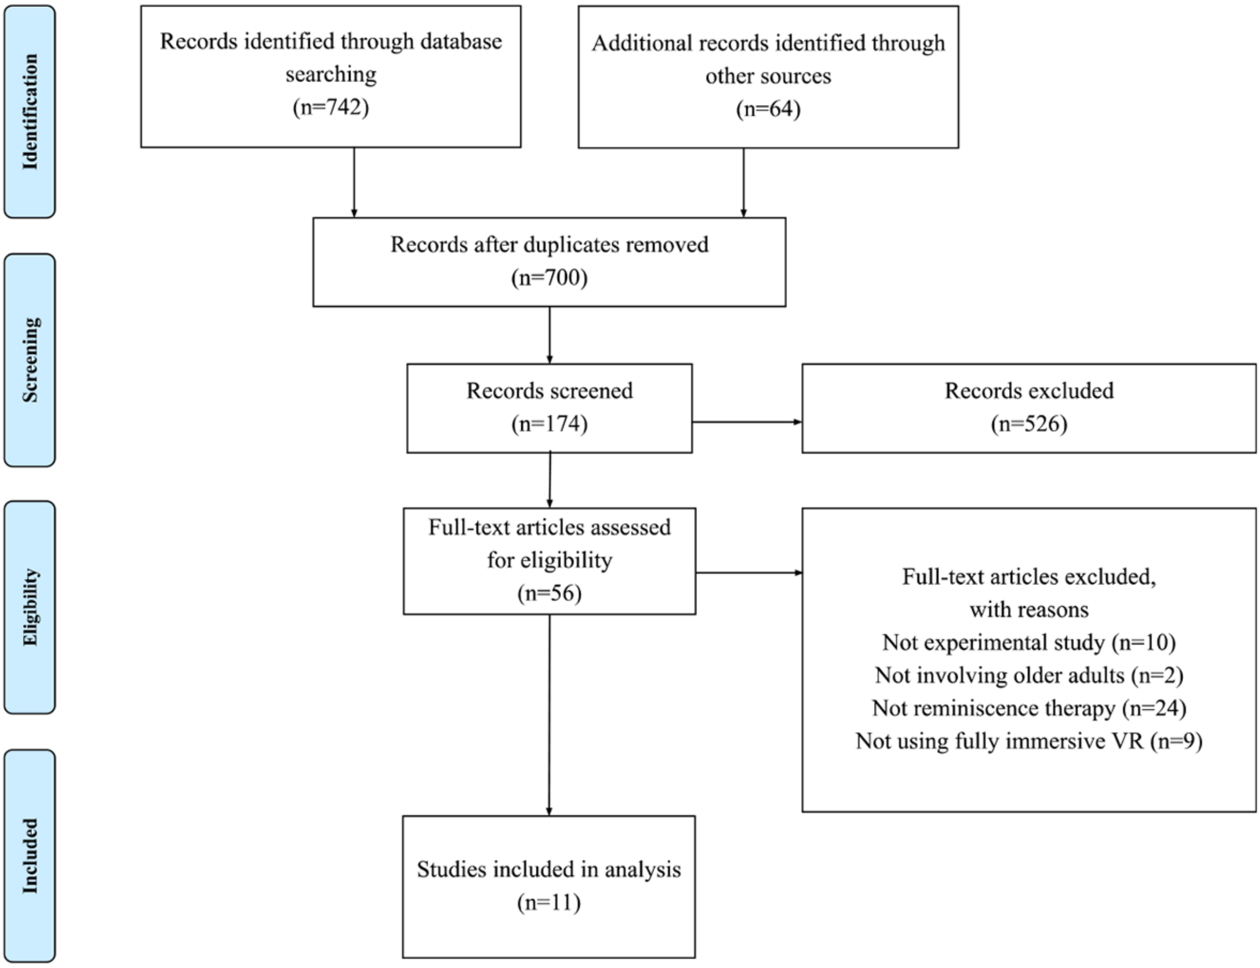
publication type such as journal or conference paper, research design, research questions, intervention information including reminiscence types, VR contents, VR types, and devices, and participant information, measurements, results, study limitations, and future research questions. One researcher charted the data into a spreadsheet, whereas another oversaw the process, critically assessed the extraction, and made necessary adjustments based on joint discussions when a disagreement arose. The charted data were further summarized and analyzed by both researchers.

Results

Search Results

The screening and selection process for eligible articles is shown in Figure 2. Additional details can be found in Multimedia Appendix 2. The first search resulted in 742 articles from the databases and 64 others from further sources such as references of selected articles. After removing the duplicates, 700 articles were retained. After the authors screened each article's title and abstract, 174 articles remained in the pool. We quickly scanned the full text and retained 56 articles for additional evaluation. Through the detailed full-text reviews, 45 studies were excluded according to the inclusion criteria, with specific reasons documented in Figure 2. Finally, 11 studies were identified for this scoping review [25,40,52-60].

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the literature search and screening process. VR: virtual reality.



Characteristics of the Selected Studies

Table 1 summarizes the general information of the selected studies, including basic article information such as authors, year of publication, and research design.

Nine articles were published in peer-reviewed journals and 2 in peer-reviewed conference proceedings. There were 4 studies that were conducted in Australia [53,56-58], 4 in Asia (China, Taiwan, and Japan) [54,55,59,60], 2 in Europe (Germany and Portugal) [25,40], and 1 in the United States [52]. The years of publication were between 2018 and 2022.

Table 1. General information summaries of selected studies.

Study, year	Publication type (study location)	Research design
Afifi et al [52], 2021	Journal paper (United States)	Mixed methods
Baker et al [53], 2021	Conference paper (Australia)	Qualitative research
Coelho et al [40], 2020	Journal paper (Portugal)	Mixed methods
Huang and Yang [54], 2022	Journal paper (Taiwan)	Quantitative research
Klein et al [25], 2018	Journal paper (Germany)	Qualitative research
Niki et al [55], 2020	Journal paper (Japan)	Quantitative research with randomized crossover research design
Saredakis et al [56], 2020	Journal paper (Australia)	Mixed methods
Saredakis et al [57], 2021	Journal paper (Australia)	Quantitative research with multisite nonrandomized controlled trial
Webber et al [58], 2021	Journal paper (Australia)	Qualitative research
Xu and Wang [59], 2020	Conference paper (China)	Randomized controlled trial
Yahara et al [60], 2021	Journal paper (Japan)	Case study

Participant Characteristics

Table 2 lists the participant characteristics of the included studies. All the studies involved older participants, with an average age between 80 and 90 years in 6 studies and 70 and 80 years in 3 studies. Two articles did not specify the participants' ages. All but one study included participants with cognitive impairments. Three studies specifically stated that they recruited people living with dementia [40,53,59]. Three studies reported other health problems in their participants, including depression, anxiety, heart diseases, mental health issues, mobility challenges, hearing difficulty, Parkinson disease, and stroke [54,56,57].

Table 2. General participant information.

Study, year	Sample size, gender, and age	Cognitive or dementia conditions	Other health conditions
Afifi et al [52], 2021	• 21 residents (female: n=18, male: n=3; mean age 83.1, SD 3.72 y) with their family members (female: n=9, male: n=12; mean age 59.86, SD 14.12 y)	• Mild cognitive impairment (n=9) • Mild dementia (n=4) • Moderate dementia (n=8)	• Not specified
Baker et al [53], 2021	• 16 older adults (female: n=5, male: n=11)	• Not specified	• Hearing difficulty (n=4) • Need mobility aid (n=2) • Mental health problem (n=1) • Parkinson disease with communication or movement problem (n=1)
Coelho et al [40], 2020	• 9 individuals (female: n=6, male: n=3; mean age 85.6, SD 7.4 y)	• Dementia (n=9) • Moderate cognitive decline (n=3) • Moderately severe cognitive decline (n=3) • Severe cognitive decline (n=3)	• Not specified
Huang and Yang [54], 2022	• 20 participants (female: n=11, male: n=9; mean age 79.0, SD 7.8 y) • Among the 20 participants, 7 were assessed 3-6 mo after the intervention	• Very mild dementia (n=2) • Mild dementia (n=15) • Moderate dementia (n=3)	• Not specified
Klein et al [25], 2018	• 6 participants (female: n=3, male: n=3; mean age 74.67, SD 1.31 y)	• Dementia (n=4) • Cognitive impairment without an unequivocal diagnosis of dementia (n=2)	• Not specified
Niki et al [55], 2020	• 10 individuals (female: n=6, male: n=4; mean age 87.1, SD 4.2 y)	• Normal cognition (n=9) • Suspected mild cognitive impairment (n=1)	• Not specified
Saredakis et al [56], 2020	• 17 participants (female: n=10, male: n=7; mean age 87.3, SD 6.3 y)	• No or minimal cognitive impairment (n=10) • Mild cognitive impairments (n=3) • Moderate cognitive impairments (n=4)	• Depressive symptoms (n=6)
Saredakis et al [57], 2021	• Experiment group: 15 participants (female: n=10, male: n=5; mean age 81.7, SD 6.6 y) • Active control: 14 participants (female: n=9, male: n=5; mean age 85.9, SD 8.1 y) • Passive control: 14 participants (female: n=9, male: n=5; mean age 87, SD 8.7 y) • Total: 43 participants (female: n=28, male: n=15; mean age 84.8, SD 8 y)	• Memory-related dementia or Parkinson disease (n=5) • Memory-related dementia or Parkinson disease (n=3) • Memory-related, dementia or Parkinson disease (n=3) • Memory-related dementia or Parkinson disease (n=11)	• Depression (n=5) • Anxiety (n=5) • Heart disease (n=8) • Stroke (n=2)
Webber et al [58], 2021	• 6 participants + 1 participant in pilot study	• With signs of cognitive impairment (n=4)	• Not specified
Xu and Wang [59], 2020	• Virtual reality–based group: 10 participants (female: n=5, male: n=5; mean age 76.7, SD 5.5 y) • Photo-based group: 10 participants (female: n=8, male: n=3; mean age 79.4, SD 2.0 y) • Blank group (verbally guided): 10 participants (mean age 78.5, SD 3.4 y)	• Mild to moderate dementia	• Not specified
Yahara et al [60], 2021	• 2 participants (female: n=1, male: n=1; age 80 and 92 y)	• Mild cognitive impairment (n=2)	• Not specified

Research Designs

There was 1 randomized crossover trial [55] and 1 randomized controlled trial [59]. Two quasi-experiments with pre-post comparisons were included [56,57], one of which had a control group. Another quasi-experiment was conducted with pre-post comparisons, wherein the intervention was offered twice a week over a 3-month period. Assessments were performed immediately and 3 to 6 months after the intervention [53]. The remaining studies included 3 qualitative studies [30,43,47], 2 mixed methods studies [40,52], and 1 case study [60]. The sample sizes ranged from 2 to 43.

FIVR Instruments and Stimuli

Tables 3 and 4 summarize the VR-related information of the selected studies, including VR types and visual contents, outcome measures, measurement methods, and results.

Table 3. Virtual reality (VR) types and visual contents used in the selected studies.

Study, year	VR type	Visual content
Afifi et al [52], 2021	• Photo based • Video based • Computer graphic based	• Virtual adventures • Virtual life story • Virtual photos and videos
Baker et al [53], 2021	• Computer graphic based	• School hall and classroom
Coelho et al [40], 2020	• Video based	• Specific streets, squares, gardens, churches, and historical landmarks that were meaningful to participants
Huang and Yang [54], 2022	• Computer graphic based (with customized narration and music that was significant to the person)	• Historical type of residence commonly found throughout Taiwan from 1960-1980 • Interactive features: the participant could use controller to hold rice to fee chickens
Klein et al [25], 2018	• Photo based • Video based	• Time travel (Berlin, 1949-1970; Paris, 20th century), movie stars (1950-1960), Germany television shows (later 20th century), or handicraft images
Niki et al [55], 2021	• Photo based • Computer graphic based	• A theme park with 6 familiar situations to those aged ≥75 y
Saredakis et al [56], 2020	• Photo based	• Personal tailored content
Saredakis et al [57], 2021	• Photo based	• Personal tailored content (not specified)
Webber et al [58], 2021	• Photo based	• Personal nominated content
Xu and Wang [59], 2020	• Computer graphic based	• A Chinese rural cottage in the 1970s with an area of 30 m2
Yahara et al [60], 2021	• Photo based	• Personal memorable places (not specified)

Table 4. Measures, measurement instruments, and results.

Study, year	Measure	Measurement instruments	Results
Afifi et al [52], 2021	• User satisfaction and perceptions • Conversational and behavioral engagement • Kinesics engagement	• Self-report questionnaire • Coding analysis of video recording • Coding analysis of video recording	• VR[a] deemed to be safe, extremely enjoyable, and easy to use by residents and family members • Residents being more conversationally and behaviorally engaged with their family members in VR sessions than in the baseline telephone calls • Residents with dementia reporting greater immersion in the VR than residents with MCI[b] • Residents with MCI being more kinetically engaged while using the VR than residents with dementia.
Baker et al [53], 2021	• Older adults' ability to participate	• Questionnaire, interviews, screen-captured video, observation notes, photographs, and short video recordings	• The virtual environment playing an effective role in surfacing memories and scaffolding reminiscence
Coelho et al [40], 2020	• Engagement and behavior • Manifestation of psychological and behavioral symptoms • Specific symptoms associated with simulation experiences • Psychological and behavioral symptomatology and the quality of life • Caregivers' opinion	• Coding analysis of observation • Coding analysis of observation • Self-report questionnaire • Structured interview with a knowledgeable informant • Semistructured interview	• Participants being very interested in exploring the immersive virtual environment and addressing positive or happy memories with frequently spontaneous communications and without simulator sickness in most cases • No significant differences found in psychological and behavioral symptomatology and the quality of life • Potentially beneficial experience for most participants reported by caregivers
Huang and Yang [54], 2022	• Overall cognitive function • Cognitive impairment • Dementia status • Depression • Caregiver burden	• CASI[c] • MMSE[d] • CDR[e] and its CDR-SB[f] • CESD[g] • ZBI[h]	• No significant differences in cognition (MMSE and CASI), global status of dementia (CDR-SB), and caregiver burden (ZBI) scores before and immediately after the intervention • No significant differences in MMSE, global status of dementia (CDR-SB), and caregiver burden (ZBI) scores immediately after the intervention and 3-6 mo after the intervention • Significantly decreased cognitive abilities (CASI) 3-6 mo after the intervention compared with those immediately after the intervention • Significantly improved depression (CESD) symptom immediately after the intervention • Significantly improved depression (CESD) symptom 3-6 mo after the intervention, compared with those immediately after the intervention
Klein et al [25], 2018	• "Destructive" and "supportive" behaviors • Usability • Caregivers' recommendations and assessment of feasibility	• Rating with a qualitative behavioral protocol • Rating with ISO 9241-110 criteria • Semistructured interview	• The prototype fostering conversations between participants and caregivers, positive interactions, and more "supportive" behaviors (eg, recognition, celebration, relaxation, validation, and facilitation) than "destructive" behaviors (eg, outpacing, ignoring, and imposition). • The prototype deemed to be suitable for daily care but being needed to be more fluently and with a bigger angle by caregivers

Study, year	Measure	Measurement instruments	Results
Niki et al [55], 2020	• Anxiety • Satisfaction and side effects	• Self-report questionnaire • Self-report questionnaire	• VR reminiscence reducing anxiety without causing serious side effects. • VR with live-action images being preferred by participants than computer graphics images
Saredakis et al [56], 2020	• Apathy; side effect; realistic experience • Verbal fluency • Expectations or enjoyment • Debriefing	• Self-report questionnaire • Task • Self-report questionnaire	• Enjoyable and acceptable experience with some negative symptoms or side effects reported by all study particiapnts • Improved semantic scores but not phonemic fluency scores found in participants • Greatest cognitive improvements after a VR reminiscence experience found in participants with higher levels of apathy
Saredakis et al [57], 2021	• Apathy • Cognition • Depression; quality of life; loneliness; side effect • Staff's opinions • Attendance and responses	• Questionnaire • Examination • Self-report questionnaire • Staff questionnaire • Coding analysis of recordings	• Most participants in the VR group preferring to watch content in VR than on a flat screen. • Participants enjoying the process of reminiscence • Participants reporting their willingness to do reminiscence again. • No significant results observed for cognition, depression, quality of life, and loneliness after therapy • No reported significant side effects or discomfort
Webber et al [58], 2021	• Perceived value; varied forms of reminiscence; challenges • Motivation and expectation	• Observation, semistructured interviews, and questionnaire • Interviews with family members	• Various past memories being elicited for all participants with mixed feelings expressed by several participants. • Virtual visits prompting various forms of reminiscence without noticeably differences compared with tablet computers. • Diverse expectations about the potential value of virtual visits revealed by families
Xu and Wang [59], 2020	• Acceptability (motivation, presence, and VR sickness) • Autobiographical memory	• Self-report questionnaire • Rating with video recording	• The VR group and the photo group with higher scores in recalling autobiographical memory than the blank group, with no significant difference between the VR group and the photo group • Higher levels of interest, motivation and perceived security, and lower levels of anxiety and fatigue in participants in both the VR group and the photo group than those in the blank group • Significantly higher level of pleasure reported in the VR group than those in the photo group. • High levels of presence with negligible sickness symptoms in the VR group
Yahara et al [60], 2021	• Anxiety; side effect and satisfaction; motivation • The burden of care • Attitude toward participation in the study	• Self-report questionnaire • Questionnaire by family members • Coding analysis of observations and videos	• Reduced anxiety and the burden of care without serious side effects by IVR[i] reminiscence • Similar effectiveness found between remote IVR reminiscence and the face-to-face session

[a]VR: virtual reality.

[b]MCI: mild cognitive impairment.

[c]CASI: Cognitive Abilities Screening Instrument.

[d]MMSE: Mini-Mental State Examination.

[e]CDR: Clinical Dementia Rating.

[f]CDR-SB: Clinical Dementia Rating–Sum of Boxes.

[g]CESD: Center for Epidemiological Studies Depression.

[h]ZBI: Zarit Caregiver Burden Interview.

[i]IVR: immersive virtual reality.

The VR goggles developed by Oculus were used in most studies (n=8): Oculus Go in 5 studies [52,55,56,58,60], Oculus Rift in 2 studies [40,54], and Oculus Quest in 1 study [57]. Coelho et al [40] used Samsung Gear VR as a head-mounted display in addition to the Oculus Rift. Xu and Wang [59] adopted the HTC VIVE Focus headset. Huang and Yang [53] used the HTC VIVE Pro version. Klein et al [30] developed a VR goggle—the "Binoculars" prototype—for their own project.

We divided FIVR stimuli into three categories: (1) photo based, which used 360° photos of real environments; (2) video based, which used 360° videos of real environments; and (3) computer graphic based, which used 360° images or animations of virtual environments generated by computer 3D modeling programs. Seven studies used photo-based VR stimuli [25,52,55-58,60]. Five studies used computer graphics–based VR, one of which incorporated recorded customized narrative and simple interactive functions via VR handles [52-55,59]. Two studies applied video-based VR [3,30], whereas 3 adopted ≥2 types of VR stimuli [25,52,55].

Types of Reminiscence Interventions

Only the study conducted by Saredakis et al [57] specified the type of reminiscence intervention used: a semistructured simple reminiscence approach emphasizing positive memories. The 2 other possible approaches, "life review" and "life story review," were not found in the rest of the articles.

Reminiscence interventions in the selected studies can be categorized based on the way they were conducted (group or individual) and the people involved (certified therapists, caregivers, or researchers). Eight studies were conducted using an individual format. Only the study by Baker et al [54] investigated how VR applications facilitated group reminiscence, in which participants communicated with each other and with a facilitator who was determined before the conversation started. During the interventions, 5 studies used researchers as facilitators [40,53,56-58]. One study used a professional team comprising pharmacists, an occupational therapist, a clinical psychologist, a certified psychologist, and a pharmacy student [60]. Interventions in 2 studies were conducted by researchers accompanied by caregivers or nursing staff [55,59]. All but 2 were conducted only through face-to-face meetings [52,60]. Participants in the study by Afifi et al [52] experienced the FIVR scenarios simultaneously with their family members who lived at a distance, interacting with each other remotely.

Health-Related and Behavior-Related Outcomes

All studies reported health- and behavior-related outcomes after reminiscence interventions. For the participants, we identified seven types of health- and behavior-related outcomes reported in the studies: (1) anxiety, (2) apathy, (3) cognitive functions or dementia status, (4) engagement, (5) depression, (6) loneliness, and (7) fatigue.

Anxiety

Three studies examined the effect of FIVR reminiscence on anxiety [40,55,60]. Instruments for measuring anxiety included the State-Trait Anxiety Inventory Self-Report Questionnaire [55,60], the Cornell Scale for Depression in Dementia, and the Neuropsychiatric Inventory [40]. Niki et al [55] found that FIVR reminiscence interventions reduced anxiety in older adults after the first session, maintaining effectiveness after the second [55]. They discovered that 360° photos are more effective than computer-generated graphics. Yahara et al [60] compared face-to-face and remote FIVR reminiscence sessions in 2 participants with mild cognitive impairments. Both participants experienced significantly decreased anxiety after the face-to-face sessions. However, after shifting to the remote session, 1 participant displayed a slight increase in anxiety, possibly due to the difficulty in remote communication, whereas the other participant's anxiety level continued to decrease. In the study by Coelho et al [40], some participants exhibited mild or intermittent anxiety and agitated behaviors during VR reminiscence sessions, which might have been caused by the disruption of participants' daily routines and unfamiliarity with the experiment environment [40].

Apathy

Apathy is defined as a "lack of feeling or emotion" or a "lack of interest or concern" [61]. Four studies assessed participants' changes in apathy after FIVR reminiscence interventions [40,56,57,60]. Saredakis et al [56,57] evaluated the effect of FIVR reminiscence therapy on apathy through verbal fluency and the Apathy Evaluation Scale. Verbal fluency, as noted by the authors, demonstrates the capability for executive control and initiation. The decline in these executive functions was associated with decreased apathy. They found that participants had improved semantic scores—the ability to name as many words as possible, starting with specific letters but not phonemic fluency scores and the ability to list more words in the category of either animals or fruit or vegetables—after the reminiscence session [56]. In another study conducted by the same team, there was an improvement in participants' apathy scale scores after reminiscence interventions [57]. Using the Cornell Scale for Depression in Dementia and the Neuropsychiatric Inventory, Coelho et al [40] found no significant improvement of apathy. Yahara et al [60] assessed participants' motivations and found that the effects of FIVR reminiscence on participants' apathy levels were mixed.

Cognitive Functions and Dementia Status

Three studies assessed the effects of the FIVR reminiscence intervention on participants' cognitive functions or dementia status, using measurement tools including the Cognitive Abilities Screening Instrument, the Mini-Mental State Examination, the Clinical Dementia Rating, the Addenbrooke Cognitive Examination III, and the Psychogeriatric Assessment Scales [53,56,57]. Two studies reported nonsignificant findings [56,57].

Huang and Yang [53] noted no significant cognitive ability differences before and immediately after the intervention, but the scores significantly declined 3 to 6 months later, implicating that the intervention might help sustain participants' cognitive functions [53]. In addition, Saredakis et al [56] observed that participants with higher apathy levels showed greater cognitive improvement after the intervention.

Engagement

Engagement was evaluated in 3 studies through observations [25,40,52]. Afifi et al [52] stated that participants were more engaged in conversations and behaviors with their family after FIVR reminiscence sessions. Those with mild cognitive impairments exhibited more kinetic engagement than people living with dementia [52]. Coelho et al [40] and Klein et al [25] found that FIVR reminiscence interventions encouraged conversation and positive participant-caregiver interactions.

Depression

Depression was measured using the Center for Epidemiological Studies Depression and the Geriatric Depression Scale (Short Form) in 2 studies [53,57]. Huang and Yang [53] noted that participants experienced significant depression improvements immediately and 3 to 6 months after the intervention. In contrast, Saredakis et al [57] reported no significant influence on depression.

Loneliness

One study assessed intervention effects on loneliness using the Three-Item Loneliness Scale, finding no significant outcomes [57].

Fatigue

One study reported less fatigue in the reminiscence sessions supported by FIVR and photos, compared with the control group with no visual aids [59].

Quality of Life

Two studies concluded that FIVR reminiscence interventions did not significantly affect participants' perceived quality of life, as assessed by the European Health Interview Survey–Quality of Life (EUROHIS-QOL) 8-item Index and the Quality of Life in Alzheimer Disease 13-item Scale [40,57].

Caregivers' Burdens

Caregivers' burdens were examined in 2 studies. Yahara et al [60] found that the FIVR reminiscence intervention reduced caregivers' burdens, but Huang and Yang [53] reported no significant differences in the caregiver burden scores before and after the intervention.

Usability and Acceptability

The usability and acceptability of FIVR in reminiscence sessions were evaluated using various methods such as a self-report questionnaire [55], behavior observation and analysis [25,40,52], and interviews [58]. Most participants indicated that FIVR reminiscence effectively evoked their past memories and was both enjoyable and acceptable. However, 1 study reported that FIVR triggered unpleasant memories in several participants [58].

Of the 4 studies addressing adverse effects, Saredakis et al [56] reported "some" negative symptoms or side effects. In contrast, the other 3 studies found "no simulator sickness" [40], "no significant side effects/discomfort" [57], and "negligible sickness symptoms" [59].

Four studies included caregivers and family members as participants [25,40,58,60]. Both Coelho et al [40] and Webber et al [58] observed that caregivers and family members viewed the FIVR reminiscence experience as potentially beneficial and valuable. However, 1 study [25] noted that caregivers found the reminiscence intervention impractical in an ambulant daycare setting because of the lack of staff for individual sessions.

Comparison Between FIVR and Other Technologies

Three studies compared different effects between the applications of FIVR and other technologies in reminiscence sessions [57-59]. Two studies found that the use of FIVR and a flat screen for reminiscence did not result in noticeable differences among participants [57,58], although participants in the study by Saredakis et al [57] preferred the FIVR experience over a flat screen. Xu and Wang [59] reported that both FIVR and printed photos could elicit the recall of autobiographical memory with no significant difference. However, the participants experienced greater pleasure in FIVR than in printed photos. In addition, Yahara et al [60] compared remote and in-person FIVR sessions and found no significant differences in terms of effectiveness.

Study Limitations

All selected articles but one discussed their study limitations. Common limitations across multiple studies were (1) small sample size [40,52,53,55,57,60], (2) the absence of a control or comparison group [40,52,53,56], and (3) participant selection bias [53,57,58]. Other limitations were related to self-report errors [56,60], the lack of long-term or follow-up assessment [40,52], the unavailability of validated assessment tools for specific components [40], being affected by the COVID-19 pandemic [57,60], exclusion of participants with severe cognitive impairments [57,59], and imperfect FIVR contents [53,55].

Future Research Directions

The authors advocated for a well-designed study with control or comparison groups, an adequate sample size, and follow-up or long-term assessment for future research on FIVR reminiscence interventions [25,40,55,56,59,60].

They also identified an extensive range of future research directions, encompassing 16 directions across 6 aspects:

1. Caregiver aspect
   - Investigating training for family caregivers to safely use FIVR for reminiscence sessions [52]
   - Examining the effects of the caregiver in charge [25]
2. Health and behavioral improvement aspect
   - Further investigation of the effects of FIVR reminiscence on psychological or behavioral symptoms, cognitive functions, and quality of life [40,53]
3. Social or engagement aspect

- Examining the social aspect of FIVR and its application in older adult care settings, at home, or with family members [52,54]
- Examining how to improve participants' engagement and adherence to the FIVR intervention [40]
- Exploring how to develop remote options for FIVR reminiscence interventions to promote use among the individual, caregiver, and family members [60]

4. Operation, implementation, or ethical aspect
    - Establishing a metric to assure successful operation of the FIVR intervention [25]
    - Investigating the barriers for the FIVR implementation and related solutions [40]
    - Identifying ethical ramifications of applying the FIVR intervention to individuals with severe dementia [40]
5. Technical aspect
    - Exploring the possibility of using log data, eye-tracking data, machine learning, and artificial intelligence to assist in the design of future FIVR reminiscence intervention prototype [25,55]
    - Understanding the added value of FIVR in reminiscence interventions [40]
    - Comparing FIVR with traditional forms of reminiscence interventions [53]
    - Investigating the method to combine FIVR reminiscence interventions with the digital mapping of media from public sources or family archives [55]
6. Human–FIVR environment interaction aspect
    - Observing participants' limb movements during the session to analyze their movements in FIVR [53]
    - Investigate how people living with dementia interact with the FIVR environment [59]
    - Exploring how the FIVR environment can create charming experiences with specific therapeutic effects [59]

Discussion

Principal Findings

In total, 11 articles [25,40,52-60] detailing empirical studies on FIVR reminiscence interventions in older adults were selected for this review. All but 1 study focused on individuals with cognitive impairments or dementia. The results showed that the intervention enhanced engagement and reduced fatigue. Although some studies reported positive effects of FIVR reminiscence sessions on participants' anxiety, apathy, depression, cognitive functions, and caregiver burden reduction, the results were not consistent across all studies. Moreover, FIVR showed overall usability and acceptability with manageable side effects among older adults.

Effectiveness of FIVR-Assisted Reminiscence Interventions in Older Adults

Overall, the review results demonstrated that FIVR-assisted reminiscence interventions, as a nonpharmacological option, were effective in improving some health- and behavior-related outcomes such as engagement and fatigue in older adults. Their effects on depression, anxiety, and apathy were not consistent. There were no significant impacts on other measures such as cognitive functions or dementia status, quality of life, and loneliness. However, it may be too soon to conclude that FIVR may not help induce further health benefits through reminiscence activities, as only 11 studies with small sample sizes and limited time frames were included in this review. Additional studies are required to provide a clearer understanding of this topic.

Usability and Acceptability

Most participants in the selected studies felt that the FIVR technology was acceptable and enjoyable. However, a study reported that reminiscence interventions may induce negative memories leading to undesirable feelings or undesirable health results [58], which raised the alarm about the selection of visual content. Otherwise, the side effects of FIVR were deemed manageable, with only a few cases reporting motion sickness. According to Chang et al [62], VR motion sickness includes symptoms such as eye fatigue, disorientation, and nausea, which are often caused by viewing dynamic content. The authors contended that motion sickness usually occurred when a person is immersed in moving VR scenes that yields an illusory perception of self-motion but their body is still in a static (standing or sitting) state. Other causes of motion sickness may be related to the fidelity of the VR stimuli and human factors [62]. Although human factors such as genetics and brain reactions may not be easy to change, the fidelity of VR stimuli can be improved, for example, by increasing the resolution or realistic sense of the visual content. There are many web-based platforms offering rich VR resources such as YouTube and Google Street Views, which were adopted by some selected studies. However, this type of content may not be ideal considering some quality problems such as distortion, glare, and low resolution. Several studies selected for this review used this content as stimuli but did not discuss quality issues in their articles.

Impact on Caregivers' Burden

Globally, there is a serious shortage in the nursing workforce; consequently, people living with dementia or mild cognitive impairments or other chronic diseases are usually cared for by informal caregivers, most of whom are family members. The care time was approximately 27.1 hours per week per person in 2021 [39], which is a burden on caregivers, especially those who provide informal care but still need to work for a living. This burden may be exacerbated as the person experiences further decline in cognitive functions along with an increase in behavioral problems and the loss of independent living. The selected studies revealed that caregivers viewed FIVR-assisted reminiscence as beneficial and valuable for people living with mild cognitive impairments and dementia. The effects of such interventions on anxiety and apathy may potentially lower caregivers' burden and companion time. Additional functions that link other people with the people living with dementia remotely through web-based platforms can better involve more family members or friends in reminiscence, which also helps reduce caregiving burden. However, as the hardware and the activity need to be set up and a facilitator is often required during the process, the reminiscence intervention may instead become an additional burden to caregivers, especially those serving in institutional care facilities where a nursing staff member provides care to multiple people.

FIVR Versus Other Technologies

In the previous section, we outlined the timeline for the different technical aids used in reminiscence interventions. Since the mid-2010s, VR has gradually become a viable option for facilitating the recall of past experiences in older adults. This evolution began with nonimmersive VR [21,27,63], displaying the virtual world through an electronic screen such as a tablet, television, or computer screen. Semi-immersive VR emerged later as another option [23,24], offering a more realistic experience by using multiple large screens or a VR Cave Automatic Virtual Environment that forms an enclosed or semienclosed environment in which to display VR content. FIVR has been considered more effective in evoking memories and is therefore more favorable for reminiscence compared with other aids, because of its fully immersive features. However, this assumption was not fully supported by evidence from the selected studies. It was noted that the results were mixed when comparing FIVR with other technical aids. For example, Saredakis et al [57] and Xu and Wang [59] found that participants preferred using FIVR for visual content over a flat screen or printed photos, whereas participants in another study reported that FIVR did not provide richer reminiscence experiences than those from an iPad [47]. In addition, FIVR may present some challenges for the participant or caregiver in controlling and manipulating the technology [58]. Nevertheless, FIVR is a relatively new technology and its application in reminiscence interventions is still in its infancy. Therefore, it may be too soon to conclude that FIVR is superior or inferior to the other traditional aids. The suitability of using FIVR may depend on the type of reminiscence intervention, content of the visual stimuli, and specific person in the session.

FIVR for People With Mild Cognitive Impairments and People Living With Dementia

Most of the selected studies focused on individuals with mild cognitive impairments or people living with dementia, making their results applicable to these groups. Only 1 study compared the FIVR effects between the population with mild cognitive impairment and that living with dementia [52]. The results indicated that people living with dementia were more immersed in VR, possibly because the realistic environment captured their attention better than it did for those with mild cognitive impairment. This is important because a higher level of immersion may lead to more emotional engagement, which would trigger unpleasant memories or emotions, resulting in adverse outcomes. Moreover, individuals with mild cognitive impairments displayed greater kinetic engagement during FIVR sessions, potentially owing to better physical health and mobility. However, the exact reasons remain unclear. Notably, there's a scarcity of studies comparing patients with mild cognitive impairments or dementia with noncognitively impaired groups. Further research comparing multiple user groups, such as young adults, healthy older adults, patients with mild cognitive impairments, and people living with dementia, is essential.

Types of FIVR Reminiscence Interventions

Only 1 study specified its intervention type as semistructured simple reminiscence. The other 2 types of reminiscence, life review and life story review, were not examined in the selected studies. Our speculations are as follows: (1) life review and life story review require professionally trained staff, posing challenges for research teams; (2) these approaches might demand more time (≥45 min), and using VR goggles for over 20 minutes could induce negative side effects; and (3) most research teams were led by design or computer science professionals, focusing on developing and testing the FIVR prototype. Life review and life story review are vital for end-of-life care, particularly for patients with cancer [15]. Consequently, further research on FIVR-supported life review is critical to address this gap.

Limitations

The limitations of this literature review are related to the characteristics of the studies and the nature of the scoping review. As noted earlier, the selected studies had some common limitations. First, the sample sizes were relatively small, ranging from 2 to 43 participants (mean 17). Only 4 studies had 20 or more participants. A small sample size has been a common issue in studies involving older adults with cognitive impairment, possibly because of the difficulties in recruitment and retention. Second, most studies were quasi-experiments, case studies, or qualitative research. Only 2 studies used control groups. Third, most studies evaluated the short-term but not the long-term effects of the interventions. Fourth, because most of the studies were conducted by the teams that created the FIVR tools, the study foci were largely on usability aspects but not on health outcomes, although these were also measured.

We attempted to identify related articles through different databases; however, the number of included studies was small (N=11). Possible reasons were that FIVR was a relatively new technology that took some time to be developed and evaluated in this field and that some studies may have been published in non–English language journals. Furthermore, there may have been publication bias; studies that did not find any significant results may not have been published. In addition, the selected studies used various research designs, sample sizes, and measurements, which presented challenges for a systematic, rigorous review, or meta-analysis.

Implications

Additional Future Research Directions

In addition to the research directions raised in the selected articles, we identified the following topics, based on this scoping review results, to further address current research gaps: (1) evaluating the impacts of FIVR quality in terms of fidelity and resolution on the effectiveness of reminiscence sessions; (2) identifying the most effective types of FIVR content, including events, locations, objects, people, sounds, and music; (3) developing and testing feasible strategies to lower caregiver burden through FIVR reminiscence interventions; (4) evaluating a specific type of FIVR reminiscence (simple reminiscence, life review, or life review therapy); and (5) comparing the effects of FIVR reminiscence on multiple user groups, such as young adults, healthy older adults, people with mild cognitive impairments, and people living with dementia. Attention to these research topics would advance our knowledge in this field.

Recommendations for Practice

Overview

FIVR has become more affordable and accessible over the last decade and therefore could be used in any reminiscence activities led by therapists, certified professionals, caregivers, and family members. It is a relatively safe therapeutic option if developed and implemented appropriately. On the basis of the review results and what we learned from our ongoing pilot studies, we provide a list of recommendations for those who would like to create FIVR stimuli to be used in reminiscence activities:

FIVR Content

Content can come from a variety of resources including web-based video sharing platforms such as YouTube and Vimeo, self-produced VR media including photos and videos, and Google Street View images. VR content can be location or event based. These locations can be childhood homes, hometowns, churches, and neighborhoods, whereas events can be weddings, birthday parties, and anniversary ceremonies. The literature suggests that selecting the most familiar places or events or those with pleasurable memories may help maximize positive outcomes. The most recent models of 360° camera allow people to produce high-quality (4K+ resolution) VR photos and videos on their own. Common camera brands include Instra360, GoPro, and Ricoh, with prices ranging from US $200 to US $800 in 2022. To reduce the possibility of motion sickness, we recommend using a fixed camera, which means that the camera is not moving around while taking videos. Once 360° photos and videos are taken, they can be uploaded to YouTube or Vimeo with minimal editing effort. Another type of VR stimulus, computer graphic–based animations or images, is not recommended for public use because it requires well-trained professionals and considerable time to build the content.

FIVR Device

We recommend consumer-grade VR goggles for reminiscence interventions because they require minimal technical support and have a less steep learning curve compared with professional goggles. As shown in the selected studies, Oculus was the go-to brand for FIVR reminiscence. The newest model in 2022 is the Oculus Quest 2, which offers its own operating system and can be used independently without connecting to computers or game consoles. It provides easy access to different websites and apps, including YouTube, and VR videos stored in video memory cards.

Types of Reminiscence Intervention

Among the 3 types of reminiscence interventions introduced in this paper, simple reminiscence is the least structured and the easiest to carry out, whereas life review and life review therapy may require specific training for the facilitator. Depending on the goals of the intervention and the facilitator’s ability, a decision about the type of intervention to be used should be made collectively by the person and the person’s caregiver, family members, and health care providers for maximal benefit.

Facilitators

We support the claim by Molinari [9] that reminiscence interventions can be conducted by both laypersons and trained professionals. In addition to providing cues during the activity, the facilitator should be able to set up the device, assist the person with accessing the VR scene, provide surveillance to avoid possible side effects including motion sickness and negative emotions, and evaluate the effectiveness of the intervention.

It should be noted that users should double-check existing practices or patient safety guidelines before applying these recommendations.

Conclusions

The growing number of older adults living with dementia or mild cognitive impairments has amplified the crises of caregiver shortage and continuously rising health care costs. We reviewed existing empirical studies that evaluated FIVR reminiscence interventions. The results indicated that such interventions, if delivered appropriately, may help improve the user’s psychological and mental health and potentially decrease the burden on caregivers. The studies also revealed a positive experience with FIVR technology, which most participants found acceptable and enjoyable. On the basis of the literature review, we identified directions for future research and provided recommendations for practice in FIVR reminiscence interventions.

Data Availability

The original data are available in Multimedia Appendix 3 [25,40,52-60].

Authors' Contributions

All authors contributed significantly to this manuscript in terms of conception, research design, data extraction and analysis, and interpretation of the review results. ZL raised the initial research questions, led the review process, critically reviewed the selected articles, and interpreted the results. WW led the article search and screening process and data analysis. ZL and WW drafted the manuscript. WY and JHS edited the technology-related content. CLK and MO edited the sections related to public health issues, the practice of reminiscence therapies or interventions, and the interpretation and implications of the findings.

Conflicts of Interest

Abstract

Background: Needle phobia, which affects 19% of children aged 4 to 6 years, prevents many children from receiving necessary or preventive medical treatments. Digital interventions have been made to target needle phobia but currently rely on distraction rather than evidence-based exposure.

Objective: We designed and evaluated a serious exposure-based mobile game called Dr. Zoo to reduce the fear of needles in children aged 3 to 6 years, where players administered shots to cartoon animals.

Methods: We conducted a mixed methods study with 30 parents (mean age 35.87, SD 4.39 years) and their 36 children (mean age 4.44, SD 1.11 years) who played the game for 5 days leading to a scheduled appointment that included an injection (eg, influenza vaccination). After the study, parents completed exit surveys and participated in semistructured interviews to evaluate ease of use, acceptability, and preliminary effectiveness of the game and to provide insights on their experience with the game to inform future developments. Interview transcripts were analyzed by 3 independent coders following an open coding process and subsequently coded and discussed to reach consensus.

Results: Parents rated their child's difficulty in completing the game as very low on average (scale 1-5; mean 1.76, SD 0.82) and were highly likely to recommend Dr. Zoo to other parents (scale 1-5; mean 4.41, SD 0.87), suggesting Dr. Zoo's strong ease of use and high acceptability. In the exit survey, parents rated their child's fear as significantly lower after participating in the study (scale 1-5; mean 3.09, SD 1.17) compared with that before participating (scale 1-5; mean 4.37, SD 0.81; z score=−4.638; P<.001). Furthermore, 74% (26/35) of the parents reported that the game had a positive impact on their child's fear or perception of needles (only 2 parents reported a negative impact). Qualitative analysis of the interview transcripts revealed potentially important features of the game in this positive impact, such as the game's interactive design, as observed in 69% (24/35) of our participants.

Conclusions: The results suggest that an evidence-based serious mobile game can be an easy-to-use, acceptable, and potentially effective intervention for changing young children's fear and perceptions of needles. Leveraging digital interventions may be a potential solution to needle anxiety as a public health concern.

Introduction

Background

The fear of needles is a critical health barrier for millions of children worldwide, with approximately 19% of children aged 4 to 6 years experiencing needle or injection phobia [1]. Needle phobia in children is also associated with distress and avoidance of medical care for chronic pediatric conditions that require routine injections, such as cystic fibrosis [2] and diabetes [3]. Needle phobia typically begins in childhood, and if left untreated, can follow into adulthood [4], which can result in the reduced uptake of vaccines, such as the influenza vaccine [5] and COVID-19 vaccine [6], as well as avoidance of other routine procedures such as blood tests, pain relief measures, and blood donation in adults [7]. Therefore, there is a pressing public health need for acceptable, scalable, accessible, and lasting approaches to treating needle phobia in children.

Although cognitive behavioral therapies (CBTs) are considered highly effective in treating needle phobias [8-11], it is neither cost-effective nor feasible to engage every patient with a mental health professional to undergo CBT. In recent years, video games and other game-like digital interventions that leverage CBT, such as virtual reality exposure therapy (VRET), have been shown to be effective in treating a variety of anxiety disorders [12,13], but no digital interventions using CBT have specifically focused on needle anxiety. Designing a similar intervention to reduce needle anxiety in young children offers numerous advantages, including scalability, cost, reduced number of office visits, and entertainment value [14-16].

Our goal is to leverage these benefits of digital intervention to improve the design and to evaluate the ease of use, acceptability, and preliminary effectiveness of an engaging and scalable digital game called "Dr. Zoo" to reduce the fear of needles and injections in children aged 3 to 6 years. We have developed a pilot version of the game, which presents children with scenarios in which the players must deliver a needle injection to a sick animal to make it feel better. We hypothesized that through repeated exposure to the in-game needle, the players (ie, children) will become more comfortable with needles and shots, which in turn will reduce needle-related anxiety. We have pilot-tested a preliminary mobile version of this game with children and their families in the Greater Pittsburgh region. The goal of this paper is to describe the development process of Dr. Zoo, including the rationale for the design, game mechanics, and presentation modality decisions. Furthermore, we report the preliminary results of several user studies and a pilot feasibility study with 36 children.

Related Works

In recent years, video games using CBT approaches have been developed with the purpose of combating anxiety as an inexpensive alternative to more conventional therapeutic methods. For example, Carlier et al [17] created a video game (New Horizon) to reduce anxiety in children with autism through relaxation techniques pulled from CBT [17], and Heng [18] created ReWIND, a role-playing video game that embeds an antecedent-belief consequence model from CBT into gameplay to treat patients with generalized anxiety disorder [18]. In these 2 examples, we see support for the application of CBT strategies in serious games that target anxiety in children.

For our problem domain of needle anxiety in children, virtual reality (VR) games that distract patients during the injection process have recently become a popular intervention, although there is little support for their long-term effects on anxiety reduction. A systematic review and meta-analysis of 10 randomized controlled trials found that overall, VR as a distraction significantly reduced children's fear of needles while undergoing needle procedures compared with children who did not receive the VR distraction [19]. However, there is no empirical evidence supporting the effectiveness of distraction-based games in producing long-term changes in children's fear of needles beyond the immediate experience itself. This suggests that a child who fears needles would need to undergo the distraction intervention for each future needle procedure because their underlying anxiety is not being resolved.

Our study departs from this distraction approach, instead focusing on exposure, which has empirical support for decreasing anxiety in the long term. Unlike distraction, exposures aim to modify a child's perception of needles to reduce fear in the long term rather than merely providing an in-the-moment solution. Exposure is a core element of CBT for child anxiety, which has been shown to be particularly effective in treating needle phobia [20]. Exposure involves presenting a child with their feared stimulus, in this case a needle, in repeated trials until the child no longer has a fear response to the stimulus. Furthermore, a gradual exposure approach where a less-feared version of the stimulus is presented first (eg, a needle in a video game) before the actual feared stimulus (eg, an actual needle during a medical appointment) can make treatment more palatable to the patient and prevent treatment dropout [21]. Through habituation to the feared stimulus (ie, a needle), a child's fear of the stimulus decreases and they learn that they can manage the situation. Therefore, they no longer need to engage in behaviors to avoid the feared stimulus (ie, a needle) to see a decrease in fear. A cognitive shift follows exposures, altering a child's perceived threat of the stimulus and their ability to cope with the threat [21,22].

Although there is no established literature on games that leverage exposure to tackle needle anxiety, there is substantial prior work in VRET games that leverage exposure to combat other forms of anxiety. Our study does not concern itself with VR directly, because we developed a *normal* or *pancake* game (as in a video game that is not VR), but this body of work in VR is necessary to discuss because it is the typical modality of digital interventions that leverage exposure. As discussed by Walkom [23], VRET is a uniquely effective and safe form of exposure therapy because of the precise control the designer has on the appearance and intensity of the stimulus and the ability of the participant to quickly abandon the simulation if the stimulus becomes overwhelming [23]. A review of 23 studies comparing VRET approaches to classical face-to-face evidence-based treatments in treating anxiety disorders found that VRET was superior to the waitlist control and comparable to traditional methods in terms of efficacy, impact, and stability of results [11].

However, little is known about the effect of less-immersive, exposure-based games (ie, non-VR) on anxiety. Exposure-based serious games that are neither VR games nor augmented reality games are exceptionally rare. In our review of the literature, we found only 1 example: a game named Lumi Nova, which was developed to address a wide range of anxiety issues (generalized anxiety, separation anxiety, social anxiety, panic disorder, and agoraphobia) in children aged 7 to 12 years [12]. Given its broader approach to helping children address a wider range of anxieties, this game does not primarily focus on exposing players to visual stimuli that resemble the object of their anxieties, as in the VRET examples discussed, but instead delivers a narrative where the player engages in puzzles to help in-game characters overcome their anxieties and facilitate goal-setting for exposure activities the player engages in outside the game [12]. In a user study of Lumi Nova (n=30), Lockwood et al [12] found that the game led children to a small but statistically significant decrease in overall anxiety after 8 weeks of play, as assessed by the player's parent or guardian using the Spence Child Anxiety Scale [12].

Our game, Dr. Zoo, has a "flat" modality, which lends itself to two core advantages over VRET: (1) it is less expensive and (2) it is more scalable, not requiring any special VR hardware outside of a mobile device. The strengths of VRET over conventional therapies may also apply to the "flat" modality of conventional mobile games, such as the designer's ability to precisely control the intensity and duration of the stimulus, the safety that comes with the player's ability to abandon the game at any point if the stimulus becomes overwhelming, and the added dimension of empathetic experiences between the patient and nonplayer characters. The impact of "flat" exposure-based games on anxiety in clinical settings will be further explored in this study. Furthermore, unlike the distraction methodology that provides only a short-term remedy in serious games for needle anxiety [24], we opted for an exposure therapy approach to create a more sustained effect by altering patients' responses to, perceptions of, and ability to cope with needles.

Objectives

In this paper, we present (1) insights into the design of a digital game to change perceptions of needles and injections in children aged 3 to 6 years and (2) insights into the ease of use, acceptability, and preliminary effectiveness of a serious game based on feedback from the players' parents.

Methods

Design Approach

We designed Dr. Zoo, a 3D adventure game for mobile devices (tablets and smartphones), as a single-player serious game to assist children in reducing their fear of needles. Above all else, our goal was exposure therapy: we wanted to create a game that requires its players to observe and interact with needles. Therefore, we decided that the game should focus on repeating a scenario in which the player must administer a vaccine to a patient. This scenario would be free of distraction, with only minimal visual elements outside of the syringe and patient, compelling the player to directly engage with the syringe for the duration of the scene. After multiple informal unstructured interviews with parents and children in our prospective age group, we decided to represent in-game virtual patients as cartoon animals. On the basis of which animals were popular among these children and which 3D animated assets we had access to, we decided that the game should center around a dragon, a dog, a penguin, a polar bear, and an orca.

We anticipated that the game would be more successful in addressing needle anxiety if the player empathized with their "patients." Our goal was to show animals in distress, have the player comfort these animals to calm them down before injecting a medication, administer the injection, and see a positive effect of the injection.

We had originally conceptualized the game as a series of injection-focused scenarios, which meant a constant presence of needles in every scene. However, in early playtests, we noticed that if the needle was always on the screen and the player was coming into the experience with especially high needle anxiety, the presence of a needle prevented players from becoming emotionally invested in interactions with the animals. This insight led us to a design decision to alternate needle and nonneedle scenes. For each animal, the player first engages in an animal-specific minigame with no needles present to build a connection and empathy between the player and the animal; these scenes do not necessarily contain therapeutically relevant content directly, instead they focus primarily on building their relationship with the character. Once the player has familiarized themselves with the animal, the scene changes to a scenario in which the animal becomes sick, and the player must administer an injection to make the animal feel better.

Dr. Zoo

Dr. Zoo is a 3D adventure game we developed in Unity for mobile devices (Android and iOS smartphones and tablets). In a series of independent chapters, the player is introduced to an animal, plays a brief minigame to solve some problem that this animal is facing, and concludes the interaction by administering an injection to the animal. The version of the game deployed for the pilot study includes 4 chapters. Although the chapters were presented to players in a specific order (by animal; Figure 1), the players were free to select and play chapters in any order they liked.

The first 2 chapters present players with a patient (a dragon named Dominic, shown in Figure 2, and a dog named Max, shown in Figure 3) who is experiencing anxiety about their scheduled vaccination. In the first chapter, Dominic the dragon is anxiously flying around the game environment, and the player must use the microphone on their device to gently talk to him until he calms down. In the second chapter, the player must play fetch with Max to help him calm down, tapping the screen to toss a ball in a backyard environment.

Figure 1. The character-select screen of Dr. Zoo. This is the screen where players choose which animal they will help next.

Figure 2. The end of the Dominic the dragon chapter.

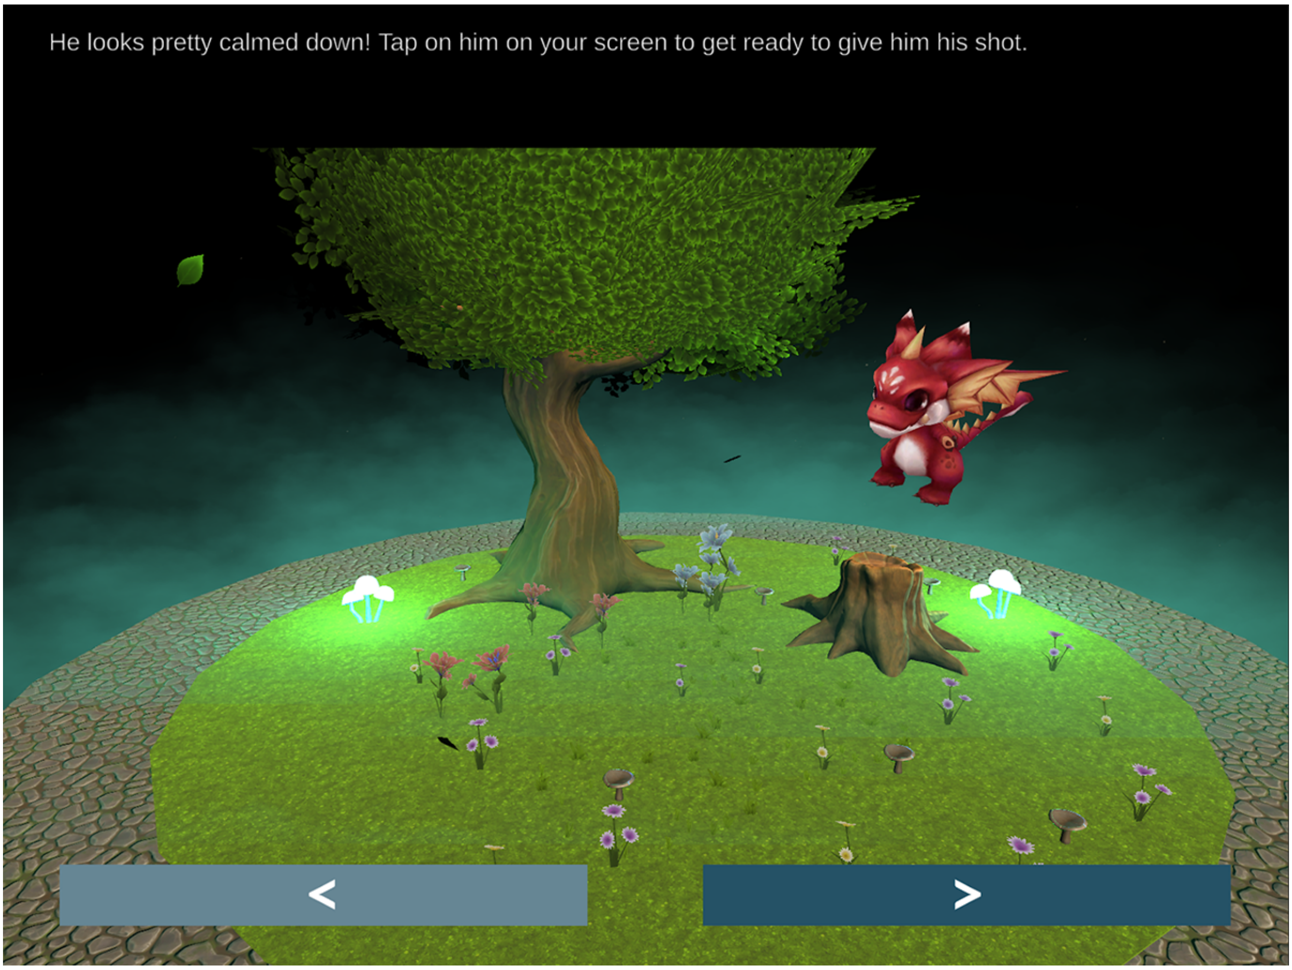

Figure 3. The player must play fetch with Max the dog in the second chapter.

The third chapter features a penguin named Penny, who lost track of her friend, a polar bear named Becky. The player must guide Penny along a short path to find Becky. The player indirectly moves Penny by tapping the ground to place fish, which Penny will walk toward and eat, as shown in Figure 4. Upon guiding Penny to Becky, Becky falls ill and requires an injection.

Figure 4. In the Penny the penguin chapter, the player must tap the screen to place the orange fish on the ground, which Penny will follow.

The fourth and final chapter features an orca named Sami, who cannot come to her appointment because her part of the ocean is full of trash. The player must search the game environment for pieces of trash among fish and other wildlife and tap on them to pick them up until all the trash has been collected, as shown in Figure 5.

Figure 5. In the Sami the orca chapter, the player must search through the small ocean environment to tap on trash objects.

The diverse set of animal-specific minigames that make up most of the content in all 4 chapters of Dr. Zoo was designed to offer an opportunity to grow fondness for the animal characters by having the player help them solve "health" problems with slightly different empathetic mechanisms. With Dominic the dragon, the player must engage verbally with the character to assist them in overcoming their anxiety. With Max the dog, the player must engage in open-ended play with a physical object (the ball), which looks to put both the player and, in the fiction of the game, the dog together in a flow state. With Becky the polar bear, the player's emotional connection is cultivated with a design strategy unique to games: searching for the character is a gameplay goal. Finally, Sami the orca's chapter takes a similar approach, pushing the player to empathize with the character through a simplified appeal to environmentalism, such that Sami only makes her triumphantly animated entrance after the player has cleaned up ocean trash. Therefore, we have 4 distinct modes of engagement with our animal patients: verbal conversation, flow-inspiring action, searching, and service.

This progression in the modes of engagement mirrors the progression in the player's relationship with the animal character, because the player experiences a wide range of character interactions from direct emotional support as if the player is a caregiver (dragon) to incidental emotional support through play (dog), to indirect care through a friend of the character (controlling the penguin to reach the polar bear), and to action that appears to have only mild relation to the character (orca). Overall, Dr. Zoo presents a useful spectrum of player and nonplayer character interactions in this context, allowing both an exploratory case study to further understand, through our feasibility study, which kinds of interactions may resonate most often in this context and, assuming players may individually differ in which interactions they prefer, crafting an experience where most players enjoy at least one of the nonplayer character interactions, even if that choice is not universal.

Our design was motivated by the idea that once a fondness for a given character is established, the player will become more invested in the impact of the injection on the animal's well-being, therefore encouraging the player to role-play as an advocate for the injection, both for their patient and, by extension, themselves. This hypothesized mechanism resembles prior work in the world of "identification," in which players self-identify with the characteristics of nonplayer characters [25]. In our game, we may see players self-identify with the courage of our virtual patients in the face of injections.

In addition, this mechanism is supported by social learning theory, which conceptualizes social behaviors as learned in part through observation and imitation [26]. In the case of Dominic the dragon's chapter, for example, the player is observing the nonplayer character's changing behavior as it manages its anxiety, so that the player may imitate that reduction of anxiety in their own conduct.

Each chapter concludes with the player administering an injection to their animal patient, as shown in Figure 6. In these scenes, the player must tap and drag a syringe into the animal's arm and hold it there for about 3.5 seconds. As the syringe is held in this position, a circular loading icon is filled, indicating progress. When the circle is filled, the syringe is removed from the screen and the patient becomes visibly more energized and does a celebratory dance with an audible cheering sound effect and confetti, as shown in Figure 7. From social learning theory, we can understand this celebration as a kind of vicarious reinforcement [26], as the player has watched the nonplayer character accept the injection and be rewarded with a celebration for being a good patient. Upon completing 1 chapter, the player is returned to a chapter-select screen to choose their next patient. The player cannot replay any chapters before completing all the 4 chapters, which triggers a finale sequence where all the animals celebrate the player's success and the game automatically restarts itself.

Figure 6. Characters in Dr. Zoo receiving an injection administered by the player.

Figure 7. A celebration sequence that occurs after the player has administered an injection.

Research Design

The pilot feasibility study followed a within-subjects design and compared parent report of child participants' fear ratings after the initial game session and final game session. The study also compared parent retrospective reports of their child's fear of needles and distress (eg, screaming, kicking, and crying) during needle-related activities in the past years before participating in the study and parent reports of their child's fear and distress during needle-related activities after participating in the study. Qualitative exit surveys were conducted to gain insights into the ease of use, acceptability, and preliminary effectiveness of the game. Furthermore, qualitative interviews were conducted to gain insight into parents' and children's experiences with the game, to inform changes for future development.

Participants

Participants were 36 children aged 3 to 6 years (mean age 4.44, SD 1.11 years) and 30 parents (mean age 35.87, SD 4.39 years). A total of 6 parents in the study enrolled 2 children to participate. Children were considered eligible for participation if they (1) were aged between 3 and 6 years; (2) previously experienced an injection, intravenous therapy, or any other activities involving syringes or needles as part of a medical treatment; (3) experienced needle anxiety based on parent report; and (4) had an upcoming medical appointment that involved syringes or needles (eg, influenza vaccination).

Children were excluded from participation if they either (1) had a fear of animals that were present in the game (ie, orca whales, penguins, polar bears, dogs, or dragons) or (2) had any seizure disorder, because some scientific literature suggests that video games could trigger seizures [27]. The demographic information of the participants is presented in Tables 1 and 2.

Table 1. Overview of participant demographics (children; n=36).

Variables	Values, n (%)
Sex	
Female	22 (61)
Male	14 (39)
Race	
White	28 (78)
White and Asian	2 (6)
White and Black or African American	1 (3)
Biracial other	3 (8)
Prefer not to answer	2 (6)
Ethnicity	
Non-Hispanic	28 (78)
Hispanic	8 (22)

Table 2. Overview of participant demographics (parents; n=30).

Variables	Values, n (%)
Sex	
Female	29 (97)
Male	1 (3)
Race	
Black or African American	1 (3)
White	26 (87)
White and Asian	1 (3)
White and Black or African American	1 (3)
Ethnicity	
Non-Hispanic	28 (93)
Hispanic	2 (7)
Income (US $)	
<24,999	1 (3)
25,000-49,999	2 (7)
50,000-74,999	4 (13)
75,000-99,999	3 (10)
>100,000	20 (67)

Ethics Approval

All research procedures were approved by the University of Pittsburgh's Institutional Review Board (STUDY20090225).

Procedures

Recruitment and Screening

Participants were recruited between May and November 2021 through a web-based university-sponsored research registry for families interested in participating in behavioral health research studies. Participants who indicated an interest in the study through the research registry were sent a prescreening Qualtrics (Qualtrics International Inc) survey to complete. Screening was performed in 2 phases. In phase 1, if the participants indicated that their child met the inclusion criteria, the research staff contacted the potential participant to schedule a web-based consent visit. A research assistant conducted the virtual consent visit either through phone or video call through Microsoft Teams, a videoconferencing platform, explaining the purpose of the study, overall procedures of the study, and risks and benefits of participation and answering any questions the parent had about the study. Parent participants then completed a web-based consent form via Qualtrics. In phase 2 of screening, following consent, participants were sent baseline surveys to complete, including a demographics survey and the Fear Survey Schedule for Children–Revised (FSSC-R) [28]. Final eligibility criteria were met based on parents reporting that their child had at least "some" fear on the FSSC-R needle phobia item.

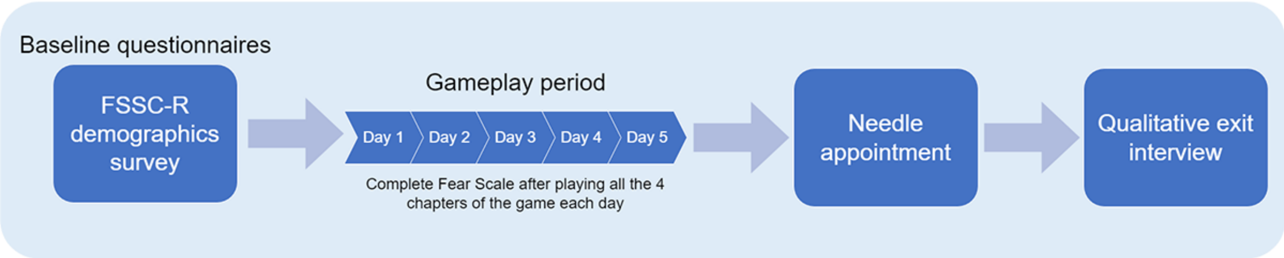
Gameplay

Approximately 2 weeks before the scheduled medical appointment involving needles or syringes, research staff instructed parents on how to download Dr. Zoo onto their smartphone or tablet device. Dr. Zoo is compatible with both Android and iOS devices. Given its low-polygon style and limited action, it does not require new or powerful hardware to run (it was tested with acceptable performance on an inexpensive Android tablet during development). Participants using an Android device were required to download and install an Android Package Kit file manually, whereas iOS users received the app through Apple's TestFlight platform. Parents were instructed to have their child complete all 4 chapters of Dr. Zoo each day for at least 5 days in a row, leading to their child's medical appointment. When their child finished playing for the day, parents completed the Children's Fear Scale [29] via a Qualtrics link embedded into the game to indicate their child's fear level while playing Dr. Zoo. No other instructions were given to parents on how to determine their child's fear level during the game. Parents also received daily SMS text message reminders to have their child play the game and complete the survey during their scheduled gameplay period.

Qualitative Exit Interview

Upon completing the medical appointment, the research staff scheduled and later completed an exit survey and interview using a semistructured interview guide with the parents (refer to Figure 8 for the timeline of assessments). Exit interviews were conducted and audio recorded on Microsoft Teams, with all but one parent (final sample of parent interviews, n=29) because the research staff were no longer able to reach the parent. The interviews lasted between 9.73 and 30.60 (mean 17.53, SD 5.38) minutes. For parents who enrolled 2 children in the study, the exit interview was conducted once with the parent while probing experiences for each child separately. The Microsoft Teams application autogenerated transcripts of the interviews, which research assistants later checked and revised manually for accuracy. Families were compensated US $20 for each child that participated in the study following the completion of the exit interview.

Figure 8. A flowchart depicting the timeline of assessments in the study. FSSC-R: Fear Survey Schedule for Children–Revised.



Protection of Health Information

Participant health information was protected using several methods. All data were stored in the university-managed OneDrive (Microsoft) database, which required research staff to log in using their university credentials to gain access. Participant data were tracked using password-protected Microsoft Excel sheets that only approved research staff had access to. Participant data were kept separate from their identifiable information, such as name, date of birth, or contact information. Furthermore, research assistants deidentified and then saved the qualitative exit interview transcripts by removing information such as name or date of birth.

Instruments and Measures

The Fear Survey Schedule for Children–Revised

The FSSC-R [28] was used to determine eligibility for the study. The measure is a widely used questionnaire that measures the number of fears and the overall level of fearfulness in children. The item used to determine eligibility for this study assesses children's fear of "Getting a shot from the nurse or doctor," on a 3-point Likert scale (0="none," 1="some," and 2="a lot"). Parents had to report that their child had at least "some" fear to be eligible for participation.

Demographics

Parents reported on demographic variables such as parent and child age, sex, race, ethnicity, and household income.

Children's Fear Scale

Parents completed the Children's Fear Scale [29] to measure children's fear levels while playing the game. This measure is a 5-point visual scale that presents 5 human faces with expressions showing different fear intensities (0: leftmost face="not scared at all" to 4: rightmost face="most scared possible"). Parents were asked to choose the face that best represented their child's response while playing Dr. Zoo. The Children's Fear Scale was used to measure the child's fear while playing the game each day.

Exit Interview

The exit interview consisted of a semistructured interview guide that asked participants about a combination of scaled questions (ie, exit survey) and open-ended questions. This allowed participants to elaborate and contextualize their responses to the scaled questions. The semistructured interview guide was developed with specific guiding questions to elicit feedback on (1) parents' and children's favorite aspects of the game, (2) parents' and children's least favorite aspects of the game, (3) parents' perceived impact of the game on their child's fear of needles or distress, and (4) suggestions for future development.

A semistructured interview guide consists of guiding questions and suggested probing questions to evoke more details from the participant, if needed. Questions can be asked in different orders to match the flow of the conversation based on the participants' responses.

To assess ease of use, we asked parents to rate how difficult it was for their child to understand how to play the game on a 5-point Likert sale (1="extremely easy" to 5="extremely difficult"). To assess acceptability, parents were asked how likely they were to recommend the game to other parents on a 5-point Likert scale (1="absolutely not" to 5="definitely yes") as well as how helpful they thought the game was in reducing their child's fear of needles on a 5-point Likert scale (1="did not help at all" to 5="helped a lot").

Finally, to assess preliminary effectiveness, parents were also asked to retrospectively rate their child's fear of needles during needle-related activities in the years before participating in the study and after participating in the study on a 5-point Likert scale (1="no fear at all" to 5="extreme fear"). Similarly, parents were asked to retrospectively rate their child's distress during needle-related activities (eg, kicking, screaming, and crying) in past years before participating in the study and after participating in the study on a 5-point Likert scale (1="completely calm" to 5="extremely agitated").

Data Collection and Analysis

Baseline and fear scale surveys were administered using Qualtrics.

Coding

A total of 3 coders—one of the first authors (postbaccalaureate) and 2 collaborators (1 master's student and 1 PhD graduate student)—were involved in the qualitative analysis process. To guide our qualitative coding process, we used a combination of deductive and inductive coding. As part of a deductive coding approach, we used the framework of the interview script to develop four distinct categories that potential codes could fall under: (1) facilitators of use, (2) barriers to use, (3) impact of the game, and (4) suggestions for future development. Then, coders used an open coding process, as described by Strauss and Corbin [30], and independently reviewed the same 6 transcripts, identifying important or repeated concepts in the transcripts, while placing them into 1 of the 4 categories. An initial codebook was then developed and used on 3 other transcripts, wherein each coder coded 1 transcript. The 3 coders met to discuss any concepts that the initial codebook failed to capture and revised the codebook to include new codes and changes to code definitions accordingly.

In the next phase, the 2 collaborators independently coded all transcripts using the revised codebook. Each transcript was coded by 2 coders, and the first coder of each transcript was responsible for segmenting the transcript into excerpts to facilitate the coding process. The coders were instructed to apply only 1 code to each excerpt. After all transcripts were double-coded, the 3 coders met to engage in an open discussion [31] to resolve any discrepancies between codes. Each coder explained their rationale for applying a specific code to an excerpt while the others listened. A final code was determined once the group reached a consensus on which code best suited the excerpt after hearing each other's rationale. Changes to the codebook were made as necessary to capture the codes better. All coding was performed using Microsoft Word and Excel.

Quantitative Analysis and Triangulation

Quantitative data were analyzed using SPSS 28 (IBM Corp). Logistic regressions were conducted to identify the relationships between participants' age and endorsement of certain qualitative codes. Triangulation of the data sources strengthened the validity of our findings and provided a more comprehensive depiction of participants' experiences with the game.

Results

Overview

In the following section, we describe quantitative, qualitative, and mixed methods findings that focus on the following aspects of the game: (1) facilitators of use (including ease of use and acceptability), (2) barriers to use, (3) impact of the game (ie, preliminary effectiveness), and (4) suggestions for future development.

Missing Data

We were unable to contact 1 parent participant after they completed their medical appointment, who did not complete the exit interview. One parent participant did not complete the fear scale survey for their child during their scheduled gameplay period. Finally, 1 parent participant was not asked to rate the difficulty in understanding because of researcher error.

Descriptive Statistics

The average scores for the FSSC-R needle phobia item were very high (scale 0-2; mean 1.89, SD 0.32), indicating a high level of baseline needle anxiety among the children in the sample. Participants completed the game on average for 5.11 (SD 1.21) days.

Transcripts were segmented into 360 excerpts in total. The codebook consisted of 17 codes, separated into 4 categories. Overall interrater reliability, as measured by Cohen κ [32], was high across all codes (pooled κ=0.86), ranging from moderate agreement to near-perfect agreement (0.59-0.98). Table 3 presents the frequency of codes, the percentage of participants who endorsed the code, and the respective κ statistic scores for each code.

Table 3. Frequency and κ statistic scores for qualitative codes by category.

Category and code	Frequency of code, n	Participants who endorsed code (n=35), n (%)	Cohen κ[a]
Facilitators to use			
Ease of use	8	8 (23)	0.93
Excitement to play game	24	18 (51)	0.98
Dominic the Dragon	22	15 (42)	0.98
Interactive	42	24 (69)	0.92
Barriers to use			
Difficulty navigating space	25	18 (51)	0.94
Injection sequence	24	14 (40)	0.93
Loss of interest	14	10 (29)	0.85

Facilitators of Use

Quantitative Results

A summary of all quantitative findings is displayed in Tables 4 and 5. The ease of use was high, with parents rating the difficulty of their children's understanding how to play the game as relatively low (scale 1-5; mean 1.76, SD 0.82). The acceptability of the game was relatively high, with parent participants being very likely to recommend Dr. Zoo to other parents (scale 1-5; mean 4.41, SD 0.87). In addition, parents rated the helpfulness of the game in reducing their child's fear of needles as moderately high (scale 1-5; mean 3.49, SD 1.27).

Table 4. Summary of descriptive statistics.

Item	Values, mean (SD)	Values, median (range)	Values (n=36), n (%)
FSSC-R[a] needle phobia item	1.89 (0.32)	2 (1)	36 (100)
Children's Fear Scale ratings across all days	0.867 (1.24)	0 (4)	35 (97)
Game difficulty	1.76 (0.82)	2 (3)	34 (94)
Likeliness to recommend game to other parents	4.41 (0.87)	5 (3)	29 (97)
Helpfulness of game	3.49 (1.27)	3 (4)	35 (97)

Table 5. Summary of Wilcoxon signed rank tests.

Variables	Median values before and after the study (range)	*z* score	*P* value
Children's Fear Scale ratings	1-0 (4-4)	−1.624	.10
Fear ratings from the exit survey	5-3 (2-4)	−4.638	<.001
Distress ratings from the exit survey	5-3 (3-4)	−4.313	<.001

Qualitative Results

Parent participants reported many aspects of the game that they and their children found enjoyable. For example, 8 (23%) out of 35 children could "figure out what to do on their own" and that the game was "simple" for them to play. In addition, 18 (51%) out of 35 children were excited to play Dr. Zoo each day, either reminding their parents that they had not yet played the game for the day or even asking them to continue to play the game past the study play period.

Each of the chapters were favored by at least some of the parents and children, though the Dominic the dragon chapter was a clear standout, with 15 (43%) out of 35 children indicating that this chapter was their favorite aspect of the game. Parents felt that this chapter was the most helpful for their children and enjoyed hearing their children comforting the dragon by "mirroring" the phrases they would often use to calm down their children, such as the following:

> *It's gonna be okay. This will help you stay safe. It'll only hurt for a second.*

Furthermore, 24 (69%) out of 35 children enjoyed that the game was interactive, for example, by being able to choose the first animal in the beginning or being the one to give the animal a vaccination. Another interactive aspect of the game that children particularly enjoyed was the celebration sequence that occurs after administering the injection to an animal, which includes confetti and characters in the game exclaiming "Yay!" Parents felt that this sequence helped their children create a positive association with vaccines.

Barriers to Use

Quantitative Results

Though ease of use was rated overall as high as explained in the *Facilitators of Use* section, an ordinal regression revealed that an increase in age (expressed in years) was associated with a decrease in the odds of rating difficulty of understanding how to play the game as high, with an odds ratio of −0.794 (95% CI −1.464 to −0.124; Wald $^{2}_{1}$=5.389; *P*=.02). In summary, parents of younger children reported that their child had more difficulty understanding the game compared with parents of older children.

Qualitative and Mixed Methods Findings

Parents reported aspects of the game that proved to be unengaging, frustrating, or unappealing for themselves or their children. Although logistic regressions revealed that age was not associated with reporting any 1 barrier code in particular (all *P* values >.05; refer to Multimedia Appendix 1 for details), 1 notable barrier reported by 18 (51%) out of 35 participants included struggling to navigate the spaces in the Penny the penguin and Sami the orca chapters. Parents reported that their children became frustrated when "they couldn't figure out how to get to the polar bear, that you had to use those arrows to get around to see the polar bear." In these instances, parents would often help their child with this sequence to continue with the rest of the chapter. Similarly, some of the children became frustrated during the Sami the orca chapter because the pieces of trash to pick up were "too tiny" and they "didn't really get the whole rotating [the screen]." This issue was most prominent when families used a smartphone for the game rather than a tablet with a larger screen.

Another aspect of the game that 14 (40%) out of 35 participants had an issue with was the injection sequence. Parents reported that their child felt uncomfortable with the length of the injection sequence and were worried that their own vaccination experience would last as long as it did in the game. In addition, parents expressed concern over the "suction noise" sound effect that was paired with the injection and described it as "off-putting." Parents also reported that their child had difficulties using their finger to move the needle into place to start the injection sequence. Furthermore, 10 (29%) out of 35 children's engagement tapered off over the course of the study gameplay period "since it was this same exact thing every day." Other barriers experienced by 4 (11%) out of 35 children included thinking the game was "too loud" or there being technical difficulties where the sound did not play at all.

Impact of the Game

Quantitative Results

Quantitative and qualitative findings demonstrated that support for the game positively affected children's fears and physical reactions to needles. On the basis of retrospective reports in the exit survey, Wilcoxon signed rank tests revealed that parents rated their child's fear as significantly lower during needle-related activities after participating in the study (median 3; mean 3.09, SD 1.17) compared with their retrospective report of their child's fear in previous years before participating in the study (median 5; mean 4.37, SD 0.81; *z*=−4.638; *P*<.001). Similarly, parents rated their children's distress (eg, crying, screaming, and kicking) during needle-related activities as significantly lower after participating in the study (median 3; mean 2.97, SD 1.42) compared with their retrospective report of their children's fear in previous years before participating in the study (median 5; mean 4.37, SD 0.88; *z*=−4.313; *P*<.001). However, there was no significant difference between the initial fear scale ratings (median 1; mean 0.97, SD 1.18) and the final fear scale ratings (median 0; mean 0.69, SD 1.13; *z*=−1.624; *P*=.10).

Qualitative Results

Qualitative results further supported the positive impact the game had on children's experience with needles, with 26 (74%) out of 35 children experiencing a reduction in fear of needles (21/35, 60%) or physical reactions (17/35, 49%) at the time of the medical appointment involving needles (as reported by their parents). However, the extent of the reduction varied. Some parents described a drastic improvement in their children's fear and physical reactions after playing Dr. Zoo compared with their previous needle appointment before participating in the study:

> *Last year during [child's] checkup for her vaccines, she hid under the table and was crying. We also had to wrestle her out of her clothes, hold her legs down. [This time], she got up on the table, she got her arm out, and then she leaned into me... and she said, 'I'm ready, Mama... It's, it's just gonna be a pinch.' And she just took a deep breath, and it was done. And she*

> *looked at me and she said, 'That was easy.' And I was shocked. But it was amazing. And I think a big part of it was playing the game.*

For other children, they showed little fear before the appointment, but were "still screaming and kicking" when the time came for the actual injection. In contrast, some parents felt that their child was "still fretting a decent amount" about their needle appointment, but there was "no crying" this time around.

Parents of 21 (60%) out of 35 children also appreciated that the game provided an opportunity to mentally prepare their child for the vaccine appointment, making their child "less nervous when it comes to [the appointment] because it gives them time to sit down and talk about it every single night leading up to it." However, 1 parent described that she disliked when her son "repeatedly" asked why he was "playing this game and if that meant that he was going to get a shot himself." Furthermore, having the game opened up the conversation with their children about the purpose and health impact of vaccines, as reported by the parents of 21 (60%) out of 35 children. One parent recounted what she would say to her child after having them play the game:

> *There are times when we need it, and they help us. Just like our dog gets shots. They make us healthy. Sometimes if we're sick, we need them. And needles are not bad, they are just to help us.*

Nonetheless, the parents of 10 (29%) out of 35 children felt that the game had no impact on either their child's fear of needles or their physical reactions to needles. Furthermore, parents of only 2 (6%) out of 35 children in the study felt that the game potentially made their child's fear surrounding needles worse because the "anticipation" of knowing that their needle appointment was around the corner made them more anxious.

Suggestions for Future Development

Parents of 25 (71%) out of 35 children gave suggestions to add features to the game to be more realistic of their child's actual needle experience. For example, parents suggested having the child place a bandage on the animal after the injection sequence to make the animal feel better, because their children felt a level of comfort after receiving a bandage after their vaccination. In accordance with some participants' discomfort with the length and sound of the injection sequence, parents suggested reducing the duration of the injection sequence and changing the sound to a short click or having no sound at all. Another suggestion was to have the animals show some apprehension surrounding the vaccination but ultimately overcome their fear. Other suggestions included adding different medical procedures, such as blood draws and being able to place the needle in different areas of the body other than the arm. Parents of 18 (51%) out of 35 children also suggested including new animal chapters to "maintain the engagement level" throughout the gameplay period. Finally, parents of 11 (31%) out of 35 children suggested some technical improvements to the game, such as adding instructions on how to move the screen around using the arrows or being more explicit in how to interact with the animals in each chapter.

Discussion

Principal Findings

Overall, Dr. Zoo demonstrated strong acceptability, ease of use, and potential preliminary effectiveness in this pilot feasibility study. Parent participants provided insightful feedback on the facilitators of and barriers to use, which will be helpful in the future development of the game.

Both quantitative and qualitative results showed that participants' satisfaction with the game was high, with many children being excited to play the game each day. In addition, parents reported that the game was easy for their children to use, although younger children had a more difficult time using the game. In addition, the chapters that required greater input from the player proved to be a barrier for some players. In particular, players had issues with both the Penny the penguin and Sami the orca chapters, which required greater game literacy to navigate 3D spaces.

Dr. Zoo also demonstrated potential preliminary effectiveness in decreasing needle anxiety, although concurrent and retrospective data appear to be conflicting. Exit surveys and interviews indicated overwhelmingly that parents found the game successful, suggesting perceived decreases in fear of needles and improvements in distress to needles during appointments. However, fear scale ratings completed by parents at the end of individual play sessions indicated no decrease in children's anxiety. A possible explanation for these contradictory results could be that the fear scale rating questionnaires captured players' fear of the game itself rather than their fear of actual needles. Another potential reason for this result could be that the fear scale ratings demonstrated a floor effect, which could have prevented the detection of statistical significance. Low fear scale ratings after play sessions indicated that players did not experience high levels of fear while playing Dr. Zoo throughout the gameplay period.

Parents used Dr. Zoo as an opportunity to educate their child about the importance of vaccines to their health and prepare them for their needle appointment. Doing so may have helped normalize the experience of receiving a vaccination, provided context for the vaccination experience, and encouraged the child to communicate their fears with their parents, all of which may have contributed to Dr. Zoo's effectiveness, despite these experiences lying outside the gameplay itself. In contrast, being reminded of their needle appointment each day while playing the game had the opposite effect for 2 children, making them more nervous in anticipation of their appointment.

Dr. Zoo's success is especially notable given its uniqueness, when compared with prior work, as a serious game that applies in-game exposure therapy techniques without augmented reality or VR. Limitations in our fear measurements made our primary analysis qualitative, which made it difficult to directly compare the effectiveness of our intervention to the body of literature with more rigorous and quantitative support for the effectiveness of VRET solutions [11]. Parent-reported fear of needles in exit interviews changed from a mean rating of 4.37 to 3.09, exhibiting a 29% reduction in fear over the course of our study.

Garcia-Palacios et al [33], in their study with the largest effect size as summarized by Opriş et al [11], found that a VRET app reduced self-reported fear of spiders, from a spider fear questionnaire [34], from 97.42 on average to 57.42, or about a 41% reduction, which is superior to Dr. Zoo. Although burdened by similar limitations, we can roughly compare our results to the state-of-the-art interventions specific to needle anxiety in children. Compared with 2 VR distractions by Özalp Gerçeker et al [35], which reported approximately 25% fear reduction on average, Dr. Zoo appears comparable in effect while having the advantage of not changing procedures of the medical appointment itself.

The Dominic the dragon chapter was a standout favorite of the 4 chapters, despite it being the most limited of the chapters in terms of opportunities for interaction with meaningful gameplay consequences. It is noteworthy that the Dominic the dragon chapter is on the leftmost point in the chapter selection screen (refer to Figure 1) and therefore may have regularly been chosen as a player's first interaction with the game, suggesting that players may have been biased toward it as a result of sequencing rather than particular content. However, it is perhaps more compelling that, at odds with the frustration found in the Penny the penguin chapter, Dominic the dragon's chapter has comparatively little opportunity to frustrate the player with difficult verbs. In terms of how the software reacts to input, the player can only (1) rotate the game environment to better view Dominic and (2) speaking into their microphone could decrease the time it takes for Dominic to calm down from 30 seconds to a minimum of 15 seconds.

Neither of these inputs create opportunities for agency comparable to the direct manipulation of objects found in the other 3 chapters (ie, throwing a ball to make Max fetch, placing a fish to make Penny walk, or tapping on trash objects to make them disappear). However, the fiction of the interaction with Dominic proved very powerful. Exit interviews indicated that players took the opportunity to engage in an emotional mirroring dialogue with the character that fundamentally aligns with our proposed empathetic mechanism. Dr. Zoo bears some similarity to Lumi Nova [12], mentioned earlier in the *Related Works* section, in that it requires the player to help nonplayer characters through anxiety issues that may resemble the player's issues. This intersection suggests that the narrative premise of the player acting in a supportive role toward others with anxiety is a therapeutic design feature worth further deployment and study.

Limitations

While discussing this work, it is important to acknowledge its limitations. The children who participated in this study were overwhelmingly White and non-Hispanic. The parents of these children were overwhelmingly White, non-Hispanic, women participants, and of the highest income category (>US $100,000/y). Children in households with higher socioeconomic status have less weekly screentime on average (including specifically video gameplay) than children in households with lower socioeconomic status [36]. This means that our game had novelty with this particular audience that may not be generalizable to children of lower socioeconomic backgrounds. In addition, although this often differs by specific vaccine, high-income White mothers are a highly vaccine-hesitant demographic, being the most likely to refuse vaccines for their children [37]. Therefore, there may be a recruitment bias, where our sample is overrepresented by the even more specific demographic of high-income White mothers who are *not* vaccine hesitant, potentially inflating the acceptability of the game compared to the general population's attitudes.

Given our interpretation of the fear scale questionnaires, we are left with little rigorous means to quantify how much the game improved anxiety over time. Our only measure of children's needle anxiety comes from the FSSC-R needle phobia item assessed at baseline to determine eligibility and their parent's retrospective assessment in exit surveys and interviews, which one may criticize as an improper proxy.

Because this was a pilot feasibility study, we did not have a control group to compare children's fear of needles between those who played the game and those who did not. Although parents provided varied feedback on the game, it is possible that receiving compensation for participating in the study biased their feedback. In addition, variability in how much parents encouraged their child to play the game or whether they let their child know about the upcoming needle appointment was not systematically assessed or controlled. Therefore, parents' impact on their child's experience with the game could not be measured. Furthermore, the children's previous experience with other games was not assessed and therefore could not be controlled for in the analyses.

Future Work

Further iterations of Dr. Zoo will focus on integrating opportunities for emotional mirroring, as seen in the Dominic the dragon chapter, into other chapters. Similarly, rewrites of the game's narrative and dialogue may be necessary to further facilitate the prospective empathetic mechanism. Exit interviews indicated a pattern of confusion particularly around the Penny the penguin chapter, which focuses on Penny trying to search for Becky the polar bear, despite them standing next to each other in the main menu screen. In addition, none of the characters have any facial animation. Especially considering that we believe the player's empathy for these characters plays an important role in the effectiveness of this game as a treatment for needle anxiety, the narrative and animation of these characters should come under closer scrutiny in future iterations.

Future evaluation of Dr. Zoo should use more rigorous assessments of the game experience, such as the Game Experience Questionnaire [38], and the impact of the game on children's fear and perception of needles. A randomized controlled trial comparing needle anxiety in children who underwent the intervention to those who did not would clarify Dr. Zoo's effectiveness. In addition, standardized measures should be used both before and after playing the game to assess the reduction in fear more accurately. Furthermore, parents' involvement and children's previous experience with games should be assessed and controlled in future studies.

Conclusions

Dr. Zoo is one of the first exposure-based mobile games designed to reduce needle anxiety in young children aged 3 to

6 years. The results of this pilot feasibility study demonstrated that Dr. Zoo had high ease of use, acceptability, and potential preliminary effectiveness. Qualitative findings provided context for the quantitative findings and revealed that children had little difficulty playing the game and were excited to play the game each day. Furthermore, parents found the game to positively impact their child's fear of and distress toward needles. Taken together, these results suggest that an evidence-based serious mobile game can be an acceptable and potentially effective intervention for changing young children's fear and perceptions of needles. Exit interviews with parent participants revealed helpful suggestions for future iterations of the game, such as opportunities for children to display emotional mirroring with the animals and changes in ease of use. Leveraging digital interventions may be a potential solution to needle anxiety as a public health concern. As more mobile games are being developed to combat anxiety, it is imperative to integrate both evidence-based components and user input to achieve the highest impact.

Acknowledgments

This research was supported by the Center for Enhancing Treatment and Utilization for Depression and Emergent Suicidality in Pediatric Primary Care, funded by the National Institution for Health (grant). The authors would like to thank the parents and children who participated in this study. Generative artificial intelligence was not used in any part of this manuscript. Article processing charges for this paper were fully paid by the University Library System, University of Pittsburgh.

Abstract

Background: The application of virtual reality (VR) in health care has grown rapidly in China, where approximately half of the population is directly exposed to secondhand smoke (SHS). As VR headsets have become increasingly popular and short video platforms have incorporated 360° videos in China, new formats and opportunities for health campaigns about SHS have emerged.

Objective: In a simulated environment of exposure to SHS, this study aims to explore the emotional and behavioral responses to enhanced social presence brought about by VR in contrast to flat-screen videos. It also aims to examine whether and to what extent video modality (360° video vs flat-screen video) and contextual cues (high threat vs low threat) influence psychometric and intentional variables among viewers.

Methods: A total of 245 undergraduate and graduate students who were nonsmokers and from a large university in China participated in this study between October 2020 and January 2021. This study created 4 different versions of a SHS experience in a café with a 2 (360° video on a head-mounted display vs flat-screen display) × 2 (high threat vs low threat) experimental design. It developed and tested a path model examining the effects of experience modality and threat levels on social presence, emotions (anger and disgust), and eventually behavioral intentions (staying away and asking for help).

Results: We found that both video modality ($P<.001$) and threat level ($P=.005$) significantly influenced social presence, whereas the interaction of video modality and threat level did not have a statistically significant effect on social presence ($P=.55$). Negative emotions mediated the relationships between social presence and SHS-related self-protective behaviors. Specifically, anger positively predicted the intention to ask smokers to stop smoking through the waitress ($P<.001$). Disgust and fear both positively predicted the intention to stay away from the SHS environment ($P<.001$ for disgust; $P=.002$ for fear).

Conclusions: This study explored the potential mediating mechanisms that influence individuals' responses to the risks of SHS in public areas. The results demonstrated that social presence and negative emotions are 2 important mediators that underlie the relationship between video modality and behavioral intention regarding SHS in a VR setting. These findings suggest that an immersive environment could be a better stimulator of anti-SHS emotions and behaviors than flat-screen videos.

virtual reality; VR; social presence; emotions; secondhand smoking

Introduction

Background

Secondhand smoke (SHS) is a severe yet understudied health issue in China. SHS could cause an increased risk of respiratory illness, heart disease, lung cancer, and asthma and worsen chronic obstructive pulmonary disease [1]. According to the Global Adult Tobacco Survey China, more than half of the Chinese people reported that they were exposed to SHS in the workplace and 44.9% of the respondents were exposed to SHS at home [2]. Data from the World Health Organization revealed that >700 million nonsmokers are exposed to SHS at least once a day in a typical week, and exposure to SHS causes 100,000 deaths annually in China [3]. Even though smoke-free policies prohibiting smoking in indoor public places came into force in certain metropolitan areas such as Beijing and Shanghai, SHS is still not rare in many restaurants, bars, and workplaces. The lack of implementation resources, together with a collectivist culture, makes it difficult to implement the smoking-free policies. The rate of exposure to SHS in public places is higher in China than in many other countries [4].

Antismoking mass media campaigns can effectively change smoking attitudes and beliefs, promote smoking cessation, and reduce adult smoking prevalence [5]. The 2006 Surgeon General's report indicated that the only way to protect nonsmokers from SHS was to eliminate exposure from smoking [6]. However, there are insufficient health campaigns targeting the SHS problem in China, and the message effect of these health campaigns has not been extensively examined and evaluated. Moreover, current SHS control programs have been mainly targeted at smokers such as male smokers [7] and smoking parents [8,9], whereas less effort has been made to encourage SHS self-protective behaviors of nonsmokers. Considering the high prevalence of SHS in indoor public places in China, interventions that target motivating SHS self-protective behaviors in nonsmokers are worth investigating. The purpose of this study was to explore the delivery channel and the content of health messages that could influence individuals' responses to SHS in public places.

Health Campaigns in Virtual Reality: The Role of Presence and Context

Virtual reality (VR) is broadly defined as a computer-generated environment that allows users to sense and interact with other objects and people as if they are in the real world [10]. Among the various types of VR technology applications, immersive virtual environments (IVEs) can be experienced by users through head-mounted displays (HMDs) such as Oculus Rift, HTC Vive, or Pico Pro. As one of the modalities of IVEs, 360° videos have become a new health communication tool and have been increasingly incorporated into health education and health promotion campaigns [11-13]. In the context of health education, a meta-analysis revealed that an IVE is more effective than other types of digital education in increasing health professionals' knowledge and cognitive skills [14]. Media messages that incorporate VR technologies can have a great impact on audiences' personal risk perceptions and thus motivate healthy behaviors. The study by Ahn et al [11] found that 1 week after exposure, a pamphlet coupled with an IVE led to less soft drink consumption than the noncoupled message (just a pamphlet). An IVE has also been used as a mode of cue presentation in smoking cessation programs [15]. However, the underlying mechanism by which VR technologies promote specific health behaviors has received scant attention.

The application of IVEs in health-related campaigns was found to be effective when the viewer is situated as a first-person *participant*. For users of an IVE, different person perspectives (ie, observer, partaker, and victim) provide distinct levels of social interactability for the intradiegetic actors. As a third person, the avatar in the virtual environment usually lacks the ability to socially interact with characters and objects. However, a first-person "victim" perspective could provide the user with an experience similar to an extrafictional victim's lived experience [16]. This study focuses on this first-person perspective of "victim" as it could most effectively position the user into the fictional experience of being harassed by SHS, where objects such as exhaled smoke or tossed cigarette butts could be oriented toward the user directly. As the study will review later, these fictional social interactions, along with the users' feeling of being forcefully engaged with socially undesirable interactions, are critical in arousing negative emotions.

Social presence, simply defined as the "sense of being with another" [17], is essential in creating effective first-person IVEs. Social presence as an inherent consequence of the modalities with varying levels of immersion has been well accepted in the VR literature [18]. Conceptually, immersion can be a technological affordance of virtual environments that works as a catalyst for the enhancement of psychological presence [19]. Although others have conceptualized immersion as a subcomponent of a larger presence construct [20], the effect brought by modality change on presence is well established. In the current case, 360° videos experienced in HMDs can arguably create a higher level of isolation for the user from the external world. More importantly, health behavior experiments using 360° videos are theoretically more interested in how the intentions of social interactive behaviors are influenced. Hence, this study focuses on social presence as a key theoretical nexus, instead of adopting a multidimensional focus on the larger concept of presence [21].

Previous studies have shown that individuals in 3D model–based and 360° video–based immersive environments experience a higher level of social presence than individuals who use flat-screen displays [22,23] because the VR setup could provide a wider range of sensory channels [24]. Apart from technological modality, contextual properties such as social cues and agency also influence social presence [18]. Social presence could be influenced by the psychological processes through which individuals interpret available social cues in a positive or negative way [18]. Studies have suggested that cues that indicate the social context (eg, the number of people) could lead to a higher level of social presence [25,26]. Similarly, the study by Lombard and Ditton [27] suggested that content variables such as human and nonhuman characters influence presence. Attentional bias toward threat suggests that people are more prone to direct their attention to threatening stimuli than to neutral stimuli [28]. Empirical research has shown that a higher level of threat could induce a prevention focus [29]. According to the explication of social presence by Cummings and Wertz [30], involvement, which manifests as focus or attention, is an important dimension of social presence. In this study, we propose that threat level is a contextual cue that influences the level of social presence. A high level of threat is expected to elicit a higher level of social presence. Thus, we propose the following hypotheses:

- Hypothesis 1: participants viewing the content in 360° video format with HMD (vs flat-screen display) feel more social presence.
- Hypothesis 2: participants viewing the content with high threat feel more social presence than those viewing the content with low threat.

However, the interaction between video modality and threat level is less certain. Studies have shown that immersive media forms could enhance the effectiveness of risk communication [31,32]. In addition, health messages with a higher level of threat are generally more persuasive than those with a lower level of threat [33]. One study found that modality (immersive VR vs flat-screen display) modulated different types of threats [34]. The study by Jin and Brown-Devlin [35] found that perceived threat is a moderator that can maximize the effects of social presence. In summary, threat emerges as an important contextual factor that influences the effect of modality on social presence. To our knowledge, there is no extant research that directly examines the interaction effect between modality and threat level on social presence. Therefore, we propose the following research question: Is there an interaction effect between video modality and threat level on social presence?

Social Presence and Emotion in the VR Setting

Generally, it has been found that IVEs have a stronger effect on eliciting emotions than the traditional flat 2D screen. The study by Jimenez et al [36] compared the player's responses to emotional content displayed on VR and flat screens. It has been found that after experiencing both conditions, VR provides a more intense and frightening experience than playing on a traditional monitor. The study by Susindar et al [37] found that emotionally charged stimuli in IVEs can effectively elicit anger and fear. Social presence, as a crucial component in creating realistic IVE experiences, is a key mechanism that produces the effect of modalities on individuals' emotional responses. Social presence is intrinsically linked to emotion. According to the study by Garrison et al [38], emotion is an indicator of social presence. The association between social presence and emotion has been demonstrated abundantly in VR research. A systematic review conducted by Diemer et al [39] showed that the association between presence and emotion has mainly been examined by means of correlations between these 2 measures. For example, 1 study found that socially anxious participants reported higher social presence than their peers in an interactive virtual environment [40]. Another study found a correlation between presence and fear in the text-anxious group in IVE [41]. Recent research has begun to explore the causal effect of social presence on emotional responses [42,43]. For example, it is found that social presence positively influenced empathy by making the user feel more comfortable in a virtual environment [44]. In health settings, the portrayal of the same antismoking message using spatial augmented reality statistically significantly influenced negative emotions through its effect on spatial presence compared with a 2D screen display [45]. On the basis of the previous literature, the following hypothesis is proposed:

- Hypothesis 3: social presence positively predicts negative emotions including anger (hypothesis 3a), fear (hypothesis 3b), and disgust (hypothesis 3c).

Effects of Emotions on Behavior in SHS Scenarios

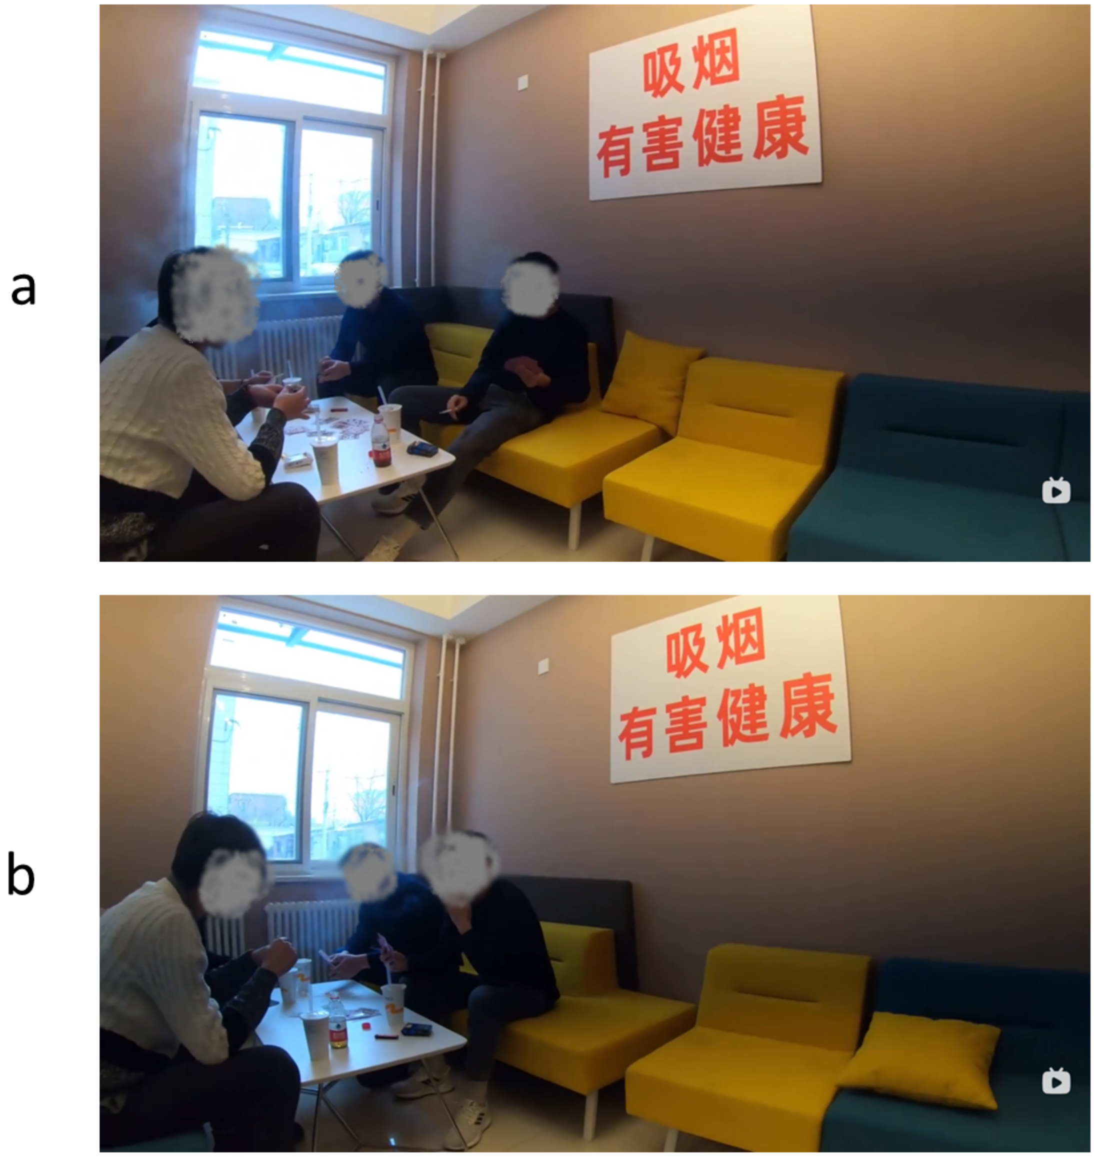
Emotion could trigger a set of responses (physiological, behavioral, experiential, and communication) that prompts individuals to address encountered problems quickly [46]. Negative emotions play a powerful role in influencing individuals' self-protective behaviors [47-50]. Eliciting negative emotional responses has been increasingly used as an effective strategy in persuasive health messages. An ample number of prior studies have demonstrated that emotionally charged information about the adverse effects of smoking could effectively promote positive behavioral change. Research has shown that emotionally arousing antismoking advertising is more likely to be recalled and promote high-order cognitive processing [51,52]. The antismoking information that aroused the strong negative emotions of fear and sadness was rated as more effective by youth participants [53].

Emotion has its action tendency. Generally, emotions can be categorized based on approach and avoidance tendencies. The approach or avoidance motivation model of emotions provides a theoretical foundation for the causal effects of emotions on behavior [54]. In this study, we focused on 3 distinct negative emotions, including anger, fear, and disgust, which are often associated with exposure to SHS or viewing antismoking messages [55-58]. Anger, characterized by approach or agonistic motivation, is often elicited by negative or offensive stimuli [59,60]. Research has suggested that anger has a motivational tendency to subdue offending stimulus [61]. Fear is associated with avoidance tendencies and inhibition [60]. In media effect research, fear is often induced by threat appeal [62]. Fear has the function of motivating efforts for self-protection [61]. Similar to fear, disgust is an avoidance or withdrawal emotion. Disgust is often associated with the appraisal theme of being too close to a potentially contaminating object [63]. Disgust is characterized by motivating physical avoidance of a disgusted object or behavior [64].

Previous research has examined the effects of personal traits and behavioral factors on SHS avoidance behavior [65]. In this study, we focused on the emotional antecedents of SHS avoidance behaviors. On the basis of a previous theoretical framework, anger, as a negative approach emotion, is hypothesized to predict the intention to ask smokers not to smoke through the waitress. Fear and disgust, both avoidance emotions, were hypothesized to predict the intention to stay away from SHS. The conceptual models are depicted in Figure 1A (model 1) and Figure 1B (model 2).

- Hypothesis 4: anger positively predicts the behavioral intention of asking smokers to stop smoking through the waitress.
- Hypothesis 5: fear and disgust positively predict behavioral intention to stay away from the SHS environment.

Figure 1. Screenshot of stimulus videos for flat-screen conditions: (A) high threat × flat-screen condition and (B) low threat × flat-screen condition.



Methods

Participants and Design

A total of 245 undergraduate and graduate students who are nonsmokers and from a large university in China participated in this study between October 2020 and January 2021 (mean age 22.16, SD 13.08 y). Individuals with a history of smoking, even if they were currently nonsmokers, were excluded from this study. The design and conduct of the experiment were preapproved and foreseen by the research ethics review board at the institution. The research recruitment flyer was distributed through the most popular Chinese social app, WeChat. Female students accounted for 166 (67.8%) out of 245 participants, whereas male students accounted for 79 (32.3%) of the participants.

A 2 (360° video in HMD vs flat-screen display) × 2 (high threat vs low threat) factorial experiment was conducted on the web and in the laboratory setting. All the participants were randomly assigned to 1 of the 4 experimental conditions. The HMD conditions included 122 participants, with 58 and 64 participants in the high-threat and low-threat condition, respectively. The flat-screen conditions included 123 participants, with 60 and 63 participants in the high-threat and low-threat condition, respectively.

Participants assigned to the flat-screen condition were asked to complete a questionnaire on the Qualtrics (Qualtrics International Inc) website using a computer, and those assigned to the VR condition (360° video in HMD) were asked to come to the laboratory. To ensure that all the participants in the flat-screen condition watched the video using a computer, we disabled the mobile function on Qualtrics and added highlighted instructions that the videos should be viewed in full-screen mode. Before the experiment, the participants electronically signed a consent form. The Pico Goblin 2 headset was used to present stimuli in the VR condition. The participants could look around in the virtual environment for the VR conditions of the study. In the VR condition, the participants were debriefed upon completing the survey. All participants who completed the study were rewarded with approximately US $5.

Power analysis assuming an α level of .05 and a power of 95% suggested that a sample size of 212 was sufficient to detect a medium effect size of *f*=0.25.

Message Manipulation

The experimental stimuli consisted of four 2-minute short videos created by the authors. The flat-screen stimulus was shot using a GoPro-4 camera, whereas the VR stimuli were shot using Insta 360 One X. All the videos were shot from the first-person perspective. Figure 1A depicts the mise-en-scène of the high-threat, flat-screen condition, and Figure 1B depicts the low-threat, flat-screen condition. The 360° videos were created using the same settings but with a 360° video camera. The HMD allowed viewers to view 360° videos under VR HMD conditions. At the beginning of the videos, the main character (the participant) was sitting in a café, where 4 men playing poker cards can be seen across the participant. In the high-threat condition, 4 smokers were smoking at the same time while playing poker cards. In the low-threat condition, there were 4 people playing poker cards but only 1 person was smoking in the video. Both the high-threat and low-threat stimuli were approximately equal in length. To ensure that the message content is the same across the 2 delivery channels, the experiment stimuli that had the same threat level were shot simultaneously.

Measures

Behavioral Intentions Toward SHS

A total of 2 SHS-related behavioral intentions were measured in this study: asking smokers to stop smoking through the waitress (mean 3.73, SD 1.03) and leaving the SHS environment (mean 2.89, SD 0.69).

Negative Emotions

Negative emotions, including anger, fear, and disgust, were measured using a self-report measure of discrete emotions [66]. Disgust was measured by 3 items: disgusted, sickened, and grossed out (mean 4.12, SD 0.68; α=.69). Fear was measured using 3 items: fearful, afraid, and scared (mean 2.89, SD 0.86; α=.73). Anger was measured using 4 items: irritated, angry, annoyed, and aggravated (mean 3.87, SD 0.87; α=.85). Participants were asked, “While you were in the virtual reality environment/watching the video, to what extent did you experience each of the following emotions?” (0=“none of this feeling”; 4=“a great deal of this feeling”).

Social Presence

Social presence was measured using the social presence–actor scale, originally developed by Lombard et al [21]. A total of 4 items from the scale were adapted in a study examining first-person social presence, of which 1 example item asked, “How often did you have the sensation that people you saw/heard and also see/hear you?” (1=“never”; 7=“always”) [12]. We used the same items whose scores were then averaged to form an overall measure (mean 3.15, SD 1.31; α=.87).

Control Variables

To determine whether any control variable should be included in the path model, we performed a randomization check on the distribution of age (continuous), gender (dichotomous), family income (categorical), and whether the participant was living with a smoker (dichotomous) across experimental conditions. Results of chi-square tests (on gender, family income, and living with a smoker) and an ANOVA test (on age) showed that there were no distributional differences in these demographic variables for age, family income, and living with a smoker. Thus, no control variables were included in the path model.

Manipulation Check

Perceived threat level was assessed by 1 question, “How much risk do you think is associated with SHS in the video you just watched?” (mean 3.95, SD 0.95).

Analysis Strategy

Path analysis based on the maximum likelihood estimation was conducted using Stata (version 15; StataCorp). Model fit was assessed based on conventional criteria, including chi-square test, root mean square error of approximation (RMSEA), standardized root mean square residual (SRMR), and comparative fit index (CFI). A value of ≤0.06 for RMSEA, <0.09 for SRMR, and ≥0.95 for CFI can be considered as a good fit [67]; we performed path analysis based on 5000 bootstrap samples.

Ethics Approval

The study was approved by the institutional review board of the School of Journalism and Communication at Beijing Normal University (protocol code BNUJ&C20200706001; July 6, 2020).

Results

Effect of Modality on Social Presence

The manipulation check was successful. A 2-way ANOVA was used to assess the effect of threat level on perceived risk. The threat levels induced statistically significantly different levels of perceived risk ($F_{1,244}$=4.87; *P*=.02). Participants in the high-threat condition were more likely to perceive the environment to be riskier (mean=4.08, SE=0.08) than those who were in the low-threat condition (mean=3.82, SE=0.09). Table 1 shows the bivariate correlations between all the variables included in the path model. The proposed models depicted in Figure 2A and Figure 2B were tested using path analysis.

Model 1 fit the data well (χ^2_7=11.1, *P*=.13; CFI=0.91, RMSEA=0.049, and SRMR=0.040). For model 2, the initial hypothesized path model did not fit the data well (χ^2_{11}=37.3, *P*<.001; CFI=0.71, RMSEA=0.099, and SRMR=0.077). On the basis of the fit indices of the hypothetical model and modification indices, we revised the model by correlating the error terms of disgust and fear. Finally, all the fit indices of model 2 were satisfied with the conservative criterion (final model: χ^2_{10}=14.4, *P*=.16; CFI=0.962, RMSEA=0.042, and SRMR=0.050). Figure 3A and 3B show the path diagrams with a standardized estimation of the final models.

Consistent with hypothesis 1, video modality was a statistically significant predictor of social presence (β=.87, SE=.23; *P*<.001). VR induced a higher level of social presence (mean 3.40, SD 1.23) than flat-screen displays (mean 2.85, SD 1.31). The threat level also positively predicted social presence (β=.34, SE=.16; *P*=.005). Participants in the high-threat condition perceived higher social presence (mean 3.29, SD 1.28) than those in the low-threat condition (mean 2.95, SD 1.30). Hypothesis 2 was supported.

Table 1. Zero-order correlations used in the path analyses[a] (N=245).

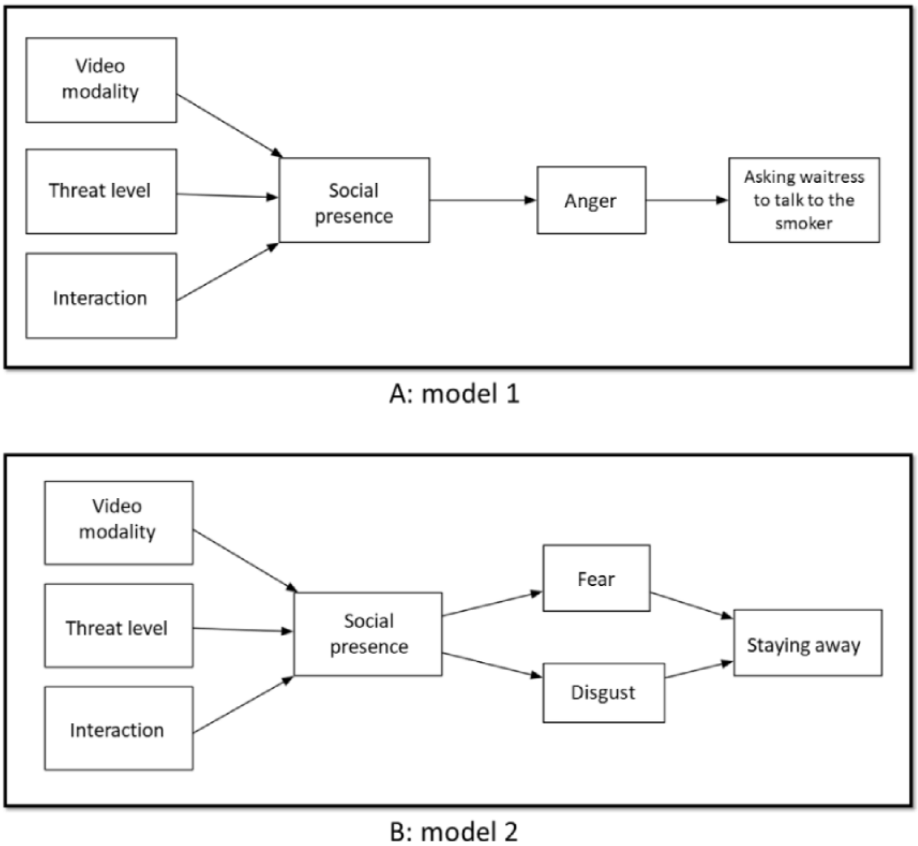

Figure 3. Proposed path models: (A) model 1 with path coefficients and (B) model 2 (adjusted) with path coefficients. ***P*<.01 and ****P*<.001.

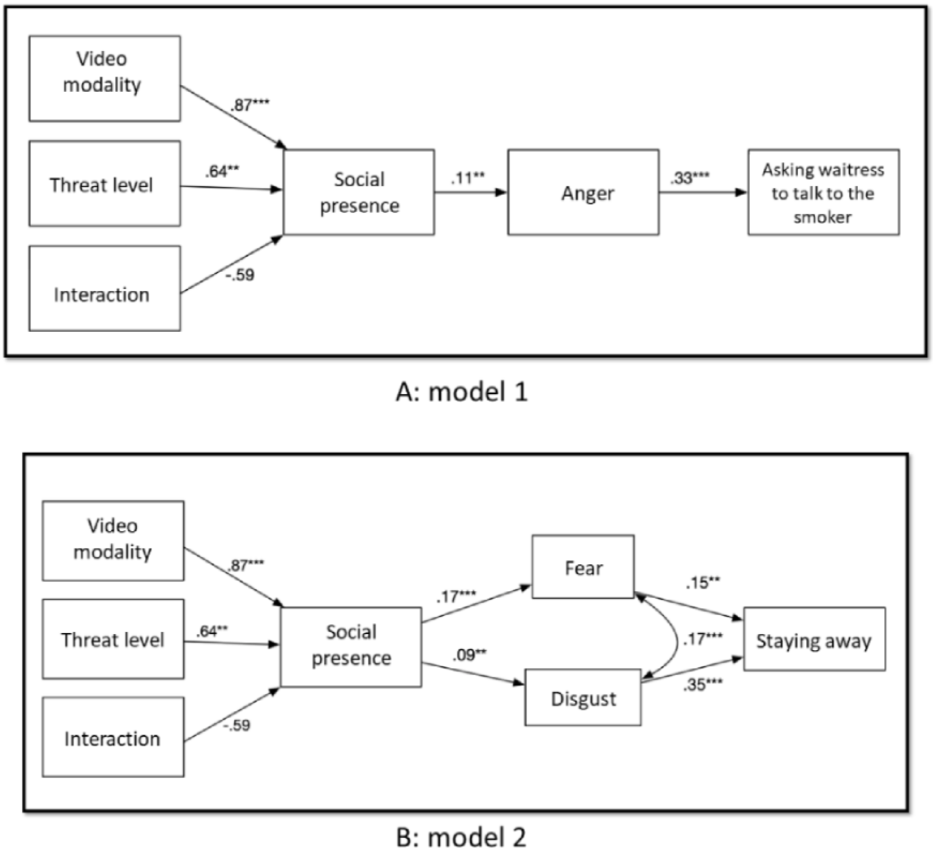

Effect of Social Presence on Emotions

In terms of research question 1, the interaction between video modality and threat level was not associated with social presence (β=−.59, SE=.32; *P*=.06). Hypothesis 3 stated that social presence positively predicts negative emotions. Consistent with our hypotheses, social presence had a direct influence on anger (β=.11, SE=.03; *P*=.008), disgust (β=.09, SE=.03; *P*=.007), and fear (β=.17, SE=.04; *P*<.001).

Effect of Emotions on SHS-Related Behaviors

As stated in hypothesis 4, anger positively predicted the intention of asking smokers to stop smoking through the waitress (β=.33, SE=.07; *P*<.001). Disgust and fear both positively predicted the intention to stay away (β=.35, SE=.06; *P*<.001 for disgust; β=.15, SE=.07; *P*=.002 for fear), supporting hypothesis 5. For model 1, the conditional indirect effect of video modality on asking smokers to stop smoking through the waitress was statistically insignificant (95% CI −0.0002 to 0.0632), and the conditional indirect effect of the threat level of asking smokers to stop smoking was statistically insignificant (95% CI −0.002 to 0.049).

Consideration on Alternative Models

For model 2, the conditional indirect effect of video modality on the intention to stay away was 0.05 (95% CI 0.01-0.09) and the conditional indirect effect of threat level of asking smokers to stop smoking was 0.04 (95% CI –0.004 to 0.067). Because we were unable to confirm the causal relationship between emotion and social presence using cross-sectional data, we also tested the 2 alternative models to further validate the results. To test an alternative model 1, anger was tested as the predictor of social presence. Such an alternative model did not fit the data well (χ^2_7=40.9, *P*<.001; CFI=0.238, RMSEA=0.141, and SRMR=0.086). The second alternative model treats fear and disgust as the predictors of social presence. The second model also did not fit the data very well (χ^2_9=98.2, *P*<.001; CFI=0.222, RMSEA=0.201, and SRMR=0.120). To test for an alternative model 2, we then correlated the error term of disgust and fear for model 2, and the fit indices were not satisfactory either (χ^2_8=73.3, *P*<.001; CFI=0.431, RMSEA=0.183, and SRMR=0.104). As both alternative models did not fit the data well, we can conclude that the proposed models in Figure 2 are more theoretically solid.

Discussion

Summary of Findings

Despite the high prevalence of SHS in China, research that focuses on public reactions to SHS in public areas remains scarce. This study explored the potential mediating mechanisms that influence individuals' responses to SHS risks in public areas based on a college student sample. To our knowledge, this is the first study to explore the health message effect of VR on SHS-related behavioral intentions of nonsmokers. Overall, we found that compared with flat-screen stimuli, the VR stimuli statistically significantly increased participants' social presence, which in turn influenced negative emotions, and negative emotions statistically significantly mediated the relationships between social presence and SHS-related self-protective behaviors. However, there was no statistically significant interaction effect between threat and video modality on social presence, despite the fact that both threat and video modality had a statistically significant individual effect on social presence. The results of this study suggest that VR is a promising channel for delivering effective health campaigns to motivate nonsmokers' self-protective behaviors in the SHS environment.

Principal Findings

This study contributes uniquely to the evidence on the persuasive effects of VR messages on self-protective behaviors related to SHS. We found that the VR-based stimulus induced a higher level of social presence than the flat-screen stimulus. Moreover, threat level, as a contextual factor, also statistically significantly influences social presence. Smoke in this study serves as an important contextual cue that creates an immersive illusion. Therefore, 1 possible explanation for the link between threat level and social presence is that the more smoke is blown by the smokers, the more likely the participants feel they are physically in the SHS environment.

This study also demonstrates the influence of social presence on negative emotions. With a higher level of social presence, participants experienced more negative emotions. This finding supports the relationship between social presence and emotions, as has been confirmed in various contexts. This study also adds to the literature by showing that different negative emotions lead to different behavioral intentions regarding SHS. More specifically, fear and disgust, as avoidance emotions, positively predicted the intention to stay away from the SHS environment, and anger, which is characterized by approach tendency, positively predicted the intention to stop others from smoking through the waitress in public places. When it comes to persuasive health messages, negative emotions could influence viewers' perception of their future personal risk, and consequently, increase their motivation to adopt self-protective behaviors.

This study has theoretical and practical implications. Theoretically, the results of this study confirm the effect of social presence on negative emotions. We developed a coherent model of SHS-related self-protection behaviors by examining the underlying mechanism linking video modality and threat level to SHS-related self-protection behaviors. We also demonstrated the effectiveness of VR in presenting highly emotionally provocative information. Practically, the findings suggest that VR could be used as an effective tool to facilitate public health campaigns that aim to encourage self-protection behaviors in SHS environments. As the study by Guixeres et al [68] suggested, VR technology provides controllable, multisensory, and interactive 3D computer-generated stimulus environments that offers intervention options that are not possible using traditional methods. By providing an immersive and interactive experience, VR can deepen one's understanding of the importance and urgency of a particular social issue [44]. VR-based health messages targeting a specific health issue thus merit further research. VR could be strategically used in health communication campaign planning to promote nonsmokers' self-protective behaviors.

Comparison With Prior Work

Consistent with the previous literature, social presence is an essential factor that influences individuals' experiences in a virtual environment. The participants who watched the VR were more likely to feel that they were in the SHS environment than those who watched a video on a computer. This study builds on this immersive effect by adding contextual smoking cues.

Previous literature shows that anger is an emotion that reflects the motivation to respond directly to immediate social threat [69]. On the basis of the results of this study, we concluded that negative emotions play an important role in controlling the adverse effects of SHS. It is recommended that public health message designers consider message features that could effectively induce negative emotions, thereby promoting health behaviors. Our study also calls for the development of culturally tailored health intervention programs in China. In collectivist cultures, it is generally considered impolite or socially inappropriate to stop others smoking directly in public places. As previous research has suggested, collectivists generally prefer maintaining harmony and a nonconfrontational conflict style [70]. Our study highlights the potential of encouraging nonsmokers to ask others for help to communicate with smokers in a collectivist cultural setting. Further research on culturally oriented communication strategies for SHS prevention is needed.

Limitations

This study had several limitations. First, only participants in VR conditions completed the survey in the laboratory setting, whereas the rest of the participants in the flat-screen conditions completed the web-based experiment. Compared with laboratory experiments, web-based experiments have more environmental variabilities, such as noise, lighting, and technical aspects of the equipment [71] (eg, although the survey cannot be accessed on phones, the variance of the screen size among participants potentially exists, and we cannot ensure the same eye distance from the screen and body posture), which may influence the level of immersion as a predictor of the model.

Second, student samples are generally more homogenous than the general public. Female college students, who constitute a large proportion of the sample, are more likely to have a higher level of knowledge about SHS [72], as it has been found in previous literature that female individuals with at least college education or nonsmokers were more likely to choose restaurants and bars with restrictions on smoking [73]. College students are also less likely to be exposed to SHS, as Chinese college students are required to live on campus, and college students are generally nonsmokers or lighter smokers.

Third, we did not measure whether the participants have gambling disorder problems. Because the experiment stimuli contain the scene of smokers playing poker cards, it is possible that participants who are addictive to gambling are less sensitive to smoking in the VR environment. Finally, there could be unmeasured variables and other confounding factors, such as participants' previous VR use and attitude toward smoking, which could have influenced the results. Future studies should also consider these factors.

Future Directions

Further research is needed to determine whether the results of this study can be replicated in other age groups. As demonstrated in this study, VR could be an effective way to enhance the behavioral intention of stopping others smoking in public areas among college students. However, it is unknown whether these results can be replicated using different sampling frames. More augmented reality–based and VR-based health interventions that target specific populations are needed. Prospective studies examining the effect of VR on health behavioral outcomes and providing conclusive evidence of the mediating mechanisms are also recommended. In addition, future research can be built from this study by examining the effects of different message delivery methods.

Conclusions

In conclusion, our study demonstrates that social presence and negative emotions are 2 important mediators underlying the relationship between video modality and behavioral intention regarding SHS in a 360°-video VR setting. More specifically, we found that (1) smoke as a contextual risk factor increases social presence alongside video modality and (2) negative emotion can be a key factor relating to behavioral intention. Health practitioners are recommended to incorporate VR technologies into more public health strategies and practices.

Abstract

Background: Opioid misuse and mental disorders are highly comorbid conditions. The ongoing substance misuse and mental health crises among adolescents in the United States underscores the importance of widely scalable substance misuse preventive interventions that also address mental health risks. Serious video games offer an engaging, widely scalable method for delivering and implementing preventive interventions. However, there are no video game interventions that focus on preventing opioid misuse among older adolescents, and there are limited existing video game interventions that address mental health.

Objective: This study aims to develop and conduct a formative evaluation of a video game intervention to prevent opioid misuse and promote mental health among adolescents aged 16-19 years (*PlaySmart*). We conducted formative work in preparation for a subsequent randomized controlled trial.

Methods: We conducted development and formative evaluation of *PlaySmart* in 3 phases (development, playtesting, and preimplementation) through individual interviews and focus groups with multiple stakeholders (adolescents: n=103; school-based health care providers: n=51; and addiction treatment providers: n=6). *PlaySmart* content development was informed by the health belief model, the theory of planned behavior, and social cognitive theory. User-centered design principles informed the approach to development and play testing. The Exploration, Preparation, Implementation, and Sustainability framework informed preimplementation activities. Thematic analysis was used to identify themes from interviews and focus groups that informed *PlaySmart* game content and approaches to future implementation of *PlaySmart*.

Results: We developed a novel video game *PlaySmart* for older adolescents that addresses the risk and protective factors for opioid misuse and mental health. Nine themes emerged from the focus groups that provided information regarding game content. Playtesting revealed areas of the game that required improvement, which were modified for the final game. Preimplementation focus groups identified potential barriers and facilitators for implementing *PlaySmart* in school settings.

Conclusions: *PlaySmart* offers a promising digital intervention to address the current opioid and mental health crises among adolescents in a scalable manner.

Introduction

Background

The opioid crisis in the United States has affected many individuals and families. Although opioid misuse among adolescents and young adults has been declining in the past few years, death from opioids among this age group has been on the rise [1]. As a result of the COVID-19 pandemic, the mortality rate from drug overdose among adolescents aged 14-18 years has increased by 94% between 2020 and 2021 [1] and again by 20% between 2021 and 2022. The total number of fatal overdoses for 2022 was 1146 [1]. Opioid-related deaths accounted for up to 85% of drug-related deaths among adolescents between 2020 and 2022 [1].

In 2020 alone, 1.4 million young adults aged 18-25 years and 396,000 adolescents aged 12-17 years misused opioids [2]. Opioid misuse is “the unhealthy use of opioids to alter reality, bring about pleasure or relieve stress” [3]. It includes the use of heroin and prescription opioids in a different way than prescribed by a physician [2,4]. Opioid misuse among adolescents increases the risk of developing an opioid use disorder (OUD) and the risk of dying from opioids [5]. Opioid misuse can also increase the risk of negative mental health outcomes and lead to suicidal thoughts and behaviors [6]. Conversely, preexisting behavioral disorders, such as depression [7], anxiety [8], adverse childhood experiences [9] and posttraumatic stress disorder [10], and misuse of cannabis [11] and alcohol [12] increase the risk of opioid misuse. Approximately 65% of youth with substance use disorder have a co-occurring mental health disorder, and adolescents with these dual diagnoses are at an increased risk of adverse medical outcomes, suicide, incarceration, and interpersonal difficulties at school and at home [13,14]. This dire situation underscores the urgency for targeted preventive interventions that are easily accessible to adolescents and that address the intersection between opioid misuse and mental health.

Opioid misuse typically starts during mid- to late adolescence [15], suggesting that this is a crucial period for targeted and accessible preventive interventions. However, widely implemented interventions for adolescents that focus on opioid misuse prevention with mental health components are lacking [16]. As over 90% of adolescents are enrolled in schools and prior school-based interventions have demonstrated feasibility for substance misuse prevention [17,18], educational institutions offer a prime setting to meet adolescents where they are [19,20]. However, existing preventive interventions directed at opioid misuse among adolescents and young adults have either been conducted outside of the school setting [21,22], such as the emergency department [22], or require the involvement of trained clinicians [23-27], both of which can limit wide scalability.

Digital interventions, such as serious video games, have shown promise for targeting health outcomes among adolescents and young adults [17,18,28-30]. Given the near ubiquity of mobile device ownership in this population, over 90% of adolescents and young adults own mobile devices [31]. Digital interventions are also widely scalable and can reach more adolescents than would be possible with in-person interventions, particularly in light of the limited availability of trained personnel [32]. Serious video games—video games designed for a primary purpose other than entertainment [17,18,28-30,33]—are effective as interventions for adolescent substance misuse [34] and are a popular medium for adolescents, as over 95% of adolescents play video games [35]. Through simulated role-playing, which is a highly effective method used for learning purposes [36], serious video games allow individuals to practice behavioral skills in a safe and entertaining manner [37,38], increasing the likelihood of translating these practiced skills into real-life situations [39,40]. Because the same content is delivered to all adolescents in the same format, video games can allow for fidelity of the intervention content [41], allow for precise monitoring of how much content each adolescent has accessed [42], and may be more cost-effective [43]. Video game interventions have demonstrated efficacy in affecting behaviors related to health promotion and disease management in many areas, including chronic diseases, healthy lifestyles, and mental well-being [17,29,30,44-50]. Existing video game interventions that target opioid misuse among adolescents are limited [51,52], have not focused specifically on older adolescents [52], are not widely implemented, have yet to be rigorously evaluated in the school setting, and do not specifically address mental health risks [51,52].

In this paper, we describe the formative work of developing a serious video game intervention, *PlaySmart*, to prevent the initiation of opioid misuse among 16- to 19-year-olds at a higher risk for substance misuse. These efforts build on previous work at the play2PREVENT Lab, which developed and evaluated evidence-based video games for prevention among children, adolescents, and young adults [17,18,29,53,54]. *PlaySmart* is funded through the National Institute of Health Helping to End Addiction Long-Term Prevention Cooperative (HPC) Initiative. The National Institute on Drug Abuse ’s primary call for HPC was to address the opioid crisis among those who experienced greater risk among youth and young adults aged 16 to 30 years. HPC consists of a coordinating center and 10 research projects funded to test and implement evidence-based interventions designed to prevent the onset or escalation of opioid misuse among at-risk groups of youth and young adults.

Aims

The aims of the formative research were to (1) conduct focus groups and interviews to inform the content and storylines of the video game, *PlaySmart*, designed to prevent the initiation of opioid misuse among adolescents aged 16-19 years; (2) develop and conduct a preliminary evaluation (playtesting) of a video game, *PlaySmart*, in partnership with Schell Games and the National School-Based Health Alliance (SBHA) to be evaluated in a subsequent large-scale randomized controlled trial (RCT); and (3) conduct focus groups and interviews among key stakeholders to understand facilitators and barriers to implementing *PlaySmart* in school settings. An RCT is currently underway to evaluate the efficacy of this video game.

Methods

Theoretical Frameworks

A total of 3 phases of formative research (development, playtesting, and preimplementation) were guided by specific evidence-based theoretical frameworks.

Frameworks That Informed Development of Game Content

PlaySmart development was informed by 3 established theories: the health belief model [55], the theory of planned behavior, and social cognitive theory [56]. These theories describe how various ecological (individual, interpersonal, and environmental) factors influence the risk of engaging in substance misuse. The health belief model suggests that the likelihood that an individual will partake in a particular behavior (opioid misuse) is driven by their belief in how susceptible they are to its negative consequences and how effective they think a behavior will diminish their susceptibility to these impacts [55,57]. The health belief model consists of 6 constructs: perceived susceptibility, perceived severity, perceived benefits, perceived barriers, cues to action, and self-efficacy [57,58]. The theory of planned behavior posits that an individual's behavior (opioid misuse) is driven by intentions that are influenced by attitudes, subjective norms, and perceived behavioral control (self-efficacy, external factors, and resources) [59-61]. Attitudes toward drug use and intentions to misuse are strongly influenced by the perception of the risk of harm [62]. As such, effective prevention interventions target these antecedent factors [28,30] to prevent eventual misuse. Social cognitive theory posits that learning occurs within a social context through an individual's interaction with their environment [63] and that the likelihood that an individual will engage in a behavior (opioid misuse) is driven by the individual's past experiences (reinforcement) and how the individual is influenced by internal factors (capability, self-efficacy) and their external environment (expectations, modeling) [63]. Social cognitive theory consists of 6 constructs: reciprocal determinism, behavioral capability, observational learning, reinforcement, expectations, and self-efficacy [63]. Improving self-efficacy is informed by the health belief model, the theory of planned action, and social cognitive theory and has been used in other video game interventions [28,30,34,64,65] targeting behavior change [65,66] such as substance misuse among adolescents [34] and found to be effective [67].

PlaySmart video game development was grounded in these theories with focus group and interview guides informed by them, and theoretical components are reflected in the game content (see focus group guide in Multimedia Appendix 1). *PlaySmart* aims to increase the perceived risk of harm from opioid misuse (primary outcome), as it has been shown to be inversely related to actual drug use [16,68,69]. Prior studies have demonstrated that older adolescents with low perception of the risk of harm from opioids are significantly more likely to misuse opioids [68,70]. The game provides opportunities to practice skills such as refusing misuse of opioids that bolster self-efficacy, model adaptive behaviors by observing the actions of other nonplayer characters in the game, and highlight avenues for resources that the player can relate to in their own life.

Framework That Informed Approach to Game Development

To guide our approach to game development, we used user-centered design principles. User-centered design is an iterative process that prioritizes the end user throughout the design and development phases [71,72]. It begins by identifying the needs of the end user and recognizing that their goals will ultimately determine the effectiveness and usefulness of the game. This is followed by the actual development of the game and its evaluation. A user-centered approach typically includes the use of multiple modalities, including focus groups, interviews, surveys, and user testing. Evidence has demonstrated that user-centered design increases the likelihood that interventions will be used by the end user [64,71,72] and has been used in the development of other digital interventions. A user-centered design has been used in the development of other digital interventions for substance use prevention among adults [73,74] and adolescents [75].

Framework That Informed Preimplementation

To inform the future implementation of *PlaySmart* in school settings, we conducted preimplementation focus groups to assist in understanding potential anticipated facilitators and barriers that could affect future implementation of *PlaySmart* in school-based settings. Preimplementation activities were informed by the Exploration, Preparation, Implementation, and Sustainment (EPIS) framework [76]. The EPIS framework is an evidence-based tool that guides and facilitates its successful implementation. During the Exploration phase, the needs of the target end user are identified to determine the best practices that would ensure that those needs are met by the new product [76]. The Preparation phase allows potential barriers and facilitators to be successfully implemented and a plan for implementation to be developed [76]. During the Implementation phase, the developed plan is conducted with ongoing monitoring [76]. During the Sustainability phase, progress is monitored on an ongoing basis to identify when adaptation might be needed [76]. The EPIS framework has been successfully used in implementation programs for youth prevention [77]. During this formative work, we conducted activities in the Exploration and Preparation phases.

Design

Formative work for the *PlaySmart* video game intervention consisted of 3 phases spanning 2 years, from early 2020 to late 2021 (Table 1). Phase 1 consisted of focus groups and interviews with a variety of stakeholders to inform the development of video game intervention. During phase 2, pilot playtesting and focus groups with adolescents were conducted to gather feedback on game content and experience, which informed the finalization of the video game. Phase 3 consisted of focus groups with school-based providers to better understand the factors to consider for successful future implementation of *PlaySmart* (preimplementation).

Table 1. Overview of aims and participant activities by phase.

Phase, primary aims, and group description	Number of focus groups or interviews	Participants (N=166), n (%)
Phase 1 (2020)		
Develop content for *PlaySmart* video game		
Youth from 4 high schools in Connecticut	7 focus groups	37 (22.3)
SBHA[a]-established YAC[b]	3 focus groups	15 (9)
SBHA personnel	5 focus groups	25 (15.1)
OUD[c] treatment providers	6 interviews	6 (3.6)
Individual in treatment for OUD	1 interview	1 (0.6)
FCD[d] prevention specialists	1 focus group	6 (3.6)
Phase 2 (2020-2021)		
Playtesting for *PlaySmart*		
High school aged youth who played through all or portions of the game	9 focus groups	33 (19.9)
Phase 3 (2020-2021)		
Explore and identify potential barriers and facilitators to implementation		
SBHA personnel	6 focus groups	26 (15.7)
SBHA-established YAC	3 focus groups	17 (10.2)

[a]SBHA: School-Based Health Alliance.

[b]YAC: youth advisory council.

[c]OUD: opioid use disorder.

[d]FCD: Freedom from Chemical Dependency.

Participants

Development

Adolescents and adults from multiple local and national stakeholder organizations engaged in the development of *PlaySmart* through focus groups and individual interviews. Adolescents were recruited from our local partner high schools and targeted e-mails to the SBHA and their youth advisory council (YAC) members. SBHA is a nationwide organization that advocates school-based health care for children and adolescents through the support of school-based health centers across the country. The SBHA oversees over 2500 school-based health centers in 49 states and Washington, DC. The YAC is a youth service group established by the SBHA and is composed of adolescents aged 16 years or older who are passionate about advocacy and share their expertise on health topics that affect students' age. Adults recruited for the focus groups and individual interviews consisted of adult affiliates of SBHA, OUD treatment providers, an individual in treatment for OUD, and prevention specialists. SBHA adult affiliates were recruited through announcements, and flyers sent through internal listserves. OUD treatment providers and individuals were recruited from the APT foundation, a nonprofit organization and one of the oldest treatment centers in the United States. Finally, prevention specialists were recruited with assistance from officials at Freedom from Chemical Dependency Prevention Works, an international nonprofit organization that aims to provide substance misuse prevention programs in schools. All participants from the development focus groups and interviews received one US $30 gift card for their time.

Playtesting

Participants from the playtesting focus groups were recruited using informational flyers and social media advertising on Facebook and Instagram. Owing to COVID-19, the research team had to adapt to web-based recruitment methods and focus group procedures. Web-based recruitment methods involved distributing electronic posters to different social media platforms and via listservs of partner organizations, such as SBHA. Participants either participated in (1) a 2-hour session that consisted of playing a portion of the game, answering follow-up qualitative questions, and receiving US $30 for their participation or (2) six 1-hour sessions that consisted of playing the entire game, completing procedure-based follow-up questions, and receiving a total of US $60 for their participation.

Preimplementation

SBHA adult affiliates and YAC members were recruited during 2 of the annual national SBHA conventions. Participants in these groups received a US $40 gift card in 1 focus group session.

Procedures

Development

The focus groups and interviews ranged from 60-90 minutes in duration. Questions focused on knowledge of opioids, perception of the risk of opioid misuse, factors contributing to misuse, and narratives from those who were opioid naive or who had personal experience with opioids, such as providers, prevention specialists, or individuals in treatment (Multimedia Appendix 1). In addition, focus groups asked about current game use and what games (if any) participants engaged with to gauge their familiarity with playing games and get a sense of the prevalence of gamers in the focus groups. Focus groups and interviews were audiotaped. Two investigators attended each focus group and conducted the interviews. One investigator led the discussion (facilitator), whereas the other took notes on observable behaviors (note-takers). After each focus group, the investigators compiled a debrief summary. Audiotapes from the focus group and the interviews were transcribed using third-party services.

Playtesting

To assess and improve the acceptability and usability of *PlaySmart*, we conducted 60- to 90-minute playtesting sessions with adolescents. Each playtesting session consisted of 2 sessions. During the first part, the participants played the game. During the second part, they completed assessment questions using either surveys (1 group) or debriefing focus groups (7 groups). See Multimedia Appendix 2 for the questions asked during playtesting.

One group played through the entire game and completed 3 surveys on knowledge, perception of risk of harm, and gameplay experience. The knowledge survey was developed by the team consisted of 5 true or false questions related to knowledge about opioids (eg, “prescription opioids can be just as deadly as heroin when they are misused”). The perception of risk survey consisted of 5 questions from the Monitoring the Future Study related to participants’ perception of the risk of harming themselves from different forms of opioid misuse (eg, “How much do you think people risk harming themselves (physically or in other ways), if they try heroin once or twice?”) [78]. Options for the risk of harm scale consisted of no risk, slight risk, moderate risk, and high risk. The gameplay experience was assessed using 8 statements on how participants felt playing the video game. Sample questions include “Playing *PlaySmart* was interesting.” Responses ranged from 1 (not at all) to 5 (a lot).

The remaining 7 groups played different aspects of the video game (storylines and minigames) and responded to open-ended questions. We asked the participants what they thought the purpose of the game was, what they learned from playing the game, what challenges they experienced while paying the game, if gameplay prompts were easy to understand, if the storylines were realistic, and recommendations to improve the game.

Preimplementation

To optimize the implementation of *PlaySmart* in school-based settings, a total of 9 focus groups with adults from SBHA personnel and adolescents from the SBHA YAC were conducted. These groups focused on facilitators and barriers, as well as how school-based health officials might be able to implement the game, possible motivations for adolescents to engage with the game, and how the game might be used in their communities. The focus groups were 60-90 minutes in length. Two investigators attended each focus group. One investigator served as the facilitator, whereas the other investigator took notes. Following the completion of each focus group, the team met for a debriefing session and a summary from the debriefing session was compiled.

Analysis

Development

Our analysis was guided via the thematic analysis by Braun and Clarke [79] to provide storylines, character depictions, and other patterns noted in the data. After each focus group and interview, debriefing summaries and notes were completed by the note-taker and reviewed by the facilitator to generate salient themes. Then, using a reflexive approach [79], conceptualized patterns from the transcriptions were added. The research team iteratively reviewed and updated the content until 6 distinct storylines emerged.

Playtesting

Data from the participant feedback were qualitatively analyzed to identify common themes. Analyses focused on players’ gameplay experience, and input was used iteratively to improve the game content and design. In this phase, we also assessed knowledge through an analysis of participant feedback on gameplay mechanics and character relations. With the game nearing its’ final form, we verified through participant responses that they understood the themes of the game and acquired the knowledge we were targeting. Because of the limited number of participants (n=3) who completed the quantitative survey on knowledge of opioids, perception of risk of harm from opioids, and gameplay experience, we were unable to analyze these results (see *Limitations*).

Preimplementation

To analyze data from the focus groups, techniques from rapid analysis [80] were performed using notes from the focus groups and debrief summaries aligned with a template of the EPIS framework. Notes and debrief summaries were analyzed using the EPIS framework to identify salient themes on potential barriers and facilitators that could impact the future implementation of *PlaySmart*.

Ethical Considerations

All the study procedures were approved by the Yale Institutional Review Board (#2000026247). Individuals who expressed interest in participating in the development or preimplementation phase provided institutional review board–approved informational sheets for the study. Individuals provided verbal assent if they were younger than 18 years of age and verbal consent if they were older than 18 years before participating. A waiver of parental consent was obtained for adolescents younger than 18 years. For participants who participated in play testing, written consent was obtained if they were 18 years or older. Written parental consent and assent were obtained from adolescents younger than 18 years.

Results

Participant Characteristics

Development

Among the high school and YAC adolescents who participated in the developmental phase focus groups (n=52), the average age was 17.1 (SD 0.87) years. The majority were female-identifying (33/52, 63%) and of non-Hispanic descent (37/50, 74%). Approximately one-third (17/52, 33%) of the adolescent participants identified as mixed or other race (Table 2). The SBHA adult affiliates and treatment providers were predominately non-Hispanic White female individuals with average ages of 40.8 (SD 12.9) and 46.4 (SD 9.8) years, respectively (Table 2).

Table 2. Demographic characteristics of participants in phase 1—development work.

Development: Focus Groups and Interviews

Overview

Multimedia Appendix 3 outlines the themes and accompanying quotes. Nine salient themes emerged from the development work with adolescents and providers, which were used to inform the content of *PlaySmart*: (1) mode of learning; (2) opioid identification; (3) perceived risk of harm: susceptibility, severity, sequences, or addiction; (4) prescription opioids; (5) opioid accessibility; (6) reasons to use; (7) mental health, (8) support systems, and (9) video game application: mechanics or game and content or storylines. The following section provides a brief description of each theme along with the associated key concepts that were included in the game to ensure that it was relevant, relatable, and accurate.

Mode of Learning

Generally, youth participants cited a lack of drug education, specifically pertaining to opioids. Even when they referenced their drug education, it was often limited to a specific grade level (eg, grade 9) or to a certain type of drug (eg, marijuana or alcohol; Multimedia Appendix 3). Many of their experiences highlighted sole exposure to opioids through the news, celebrities, or media, providing further evidence of the lack of formal opioid education in the youth population.

Opioid Identification

Across youth focus groups, many gaps in knowledge of opioids have emerged. Although most had heard the term “opioid” before, many were unable to accurately describe or categorize opioids. Adolescents reported that they recognized the names Percocet, Oxycontin, and Heroin, but did not classify them as opioids. This was especially true for heroin (Multimedia Appendix 3). A few participants incorrectly categorized other substances, such as marijuana, as opioids. Interviews with treatment providers confirmed this gap in knowledge, underscoring that adolescents only hold a vague understanding of opioids.

Perceived Risk of Harm

Drawing on this lack of knowledge, many youth participants perceived their susceptibility to risk from opioid misuse as low. A lack of opioid misuse prevalence in their age group was often cited as the primary reason for low susceptibility; many claimed that problems only existed in college students or older populations (Multimedia Appendix 3). When treatment providers reflected on their experiences with the youth, this false belief was further supported. Youth participants recognized the severity of harm from heroin but did not perceive prescription opioids to be as harmful. They attributed this logic to the mode of delivery of some opioids (eg, prescription pills and codeine drink) compared with heroin (eg, injection). Despite this, participants in both youth and provider focus groups generally understood the psychological, social, and physical harms of addiction (Multimedia Appendix 3).

Prescription Opioids

Youth participants often identified medical professionals as partly responsible for the opioid misuse crisis. Many shared stories of friends or close relatives prescribed opioids without proper information from the physician. Treatment providers confirmed that this was often how youth were introduced to opioids, either by their own prescription or by a prescription of someone they were close to (Multimedia Appendix 3). The participants shared that this initial prescription often led to misuse.

Opioid Accessibility

Participants in both the youth and provider focus groups shared that accessing opioids was often quite easy—in a medical setting, in their households, and around their peers. They attributed this to the normalized prescription of opioids and teens' general curiosity regarding foreign substances (Multimedia Appendix 3). Youth participants shared that if it was available, it was more likely and more easily used for recreational purposes. Similarly, many participants spoke of "lean" or "dirty sprite" (formally known as codeine) as fairly accessible, easily ingestible, and widespread (Multimedia Appendix 3).

Reasons to Use

Participants in both youth focus groups and provider interviews highlighted an array of potential reasons for opioid misuse. Peer pressure has been frequently cited as a catalyst for this behavior, although not in the stereotypical context. This peer pressure was more implicit and geared toward blending in rather than being perceived as "cool" (Multimedia Appendix 3). The youth and provider participants also cited maladaptive coping as a reason for opioid misuse. Participants reported a variety of reasons for the need to cope, including the death of a loved one, major stress, mental health issues, and "a way out" (Multimedia Appendix 3).

Mental Health

Youth participants mentioned an abundance of mental health concerns; some were related to opioid misuse, whereas others were independent of it. They specified a wide range of stressors that contribute to mental health issues and opioid misuse (Multimedia Appendix 3). While recognizing these stressors, they also described their own perceptions of someone experiencing mental health issues. Youth had a wide range of opinions on seeking help. Some were supportive of professional support, whereas others expressed strong hesitance. Stigma and the lack of trust were common reasons for this resistance, so the importance of finding a good match with a provider was heavily emphasized.

Support Systems

Most youth participants stated that adults were a necessary support system for resilience, recovery, and well-being, although they did not agree that adults should be parents or guardians. Many shared personal advice on how to support a peer but also recognized the limitations of peer-to-peer support (Multimedia Appendix 3). Youth participants also highlighted the importance of being emotionally in tune with themselves and how that alone could serve as a form of support (Multimedia Appendix 3).

Video Game Application

Of the 52 youths, 41 (79%) who participated in the development work mentioned playing or having played more than one game; 11 (21%) participants did not mention playing any games. More specifically to our intervention, youth participants provided their feedback on video game details, such as mechanics, esthetics, and storyline content. Generally, they recommended that the game be simple but challenging (Multimedia Appendix 3). In terms of storylines, all youth participants provided valuable information specific to interactions with parents, situations at parties, and even route friendships could take.

Development: PlaySmart Video Game Intervention

On the basis of the information gleaned from our development focus groups and interviews, our research team collaborated with our game development partners, Schell Games, to launch and finalize the video game intervention, *PlaySmart*. Game content was directly informed by focus groups and interviews, similar to other digital interventions targeting adolescents [29,30,53,54,75,81-84].

The cornerstones of the *PlaySmart* video game intervention are (1) six storylines that form the narrative foundation: *Trading Wisdom*, *Lean on Me*, *A Friend in Need*, *Grandma's Pills*, *Tough Love*, and *A New Direction*; (2) six minigames that provide skill-building opportunities: *Risk Sense*, *Stress Sense*, *Refusal Power*, *Social Media Game*, *Choice Power*, and *Know Power*; and (3) a participant tracker: *Future Sense*. At the beginning of the game, players review their future self in *Future Sense* to see how poorly their lives turned out because of opioid misuse and are tasked with changing their future by playing *PlaySmart*. The use of the future self-motivates players to do better in the present by drawing on evidence that shows that imagining the future self and highlighting similarities between the current and future self can influence positive behavior change [85].

These 6 storylines encompass major topics that address opioid misuse and mental health. In *Trading Wisdom*, the player learns to use opioid prescriptions safely, the consequences associated with misuse, and nonpharmacologic and nonopioid alternatives for pain management. In *Lean on Me*, the player learns about high-risk situations where opioid misuse is likely to occur (party), the role of peer pressure, how to refuse an offer to use opioids, and the dangers of misusing opioids. In a *Friend in Need*, the player learns about how mental stress increases the risk of opioid misuse, the benefit of seeking support from trusted adults, and how they can be supportive to their friends. In *Grandma's Pills*, players learn about the dangers of using prescriptions that do not belong to them, including overdose and strategies from refusing opioids when offered by family members. In *Tough Love*, the player learns to set boundaries in close relationships where opioid misuse is an issue, and how to support people close to you who are struggling with opioid misuse. In *A New Direction*, the player learns of mental health resources, existing myths around mental health and stigma and is empowered to seek mental health care when needed. Throughout gameplay, players have options to make a bad or good choice, thus practicing decision-making skills. In addition, we expect to increase the perception of the risk of harm among players through scenarios that highlight the dangers of opioid misuse. Links to other trusted websites such as the National Institute on Drug Abuse are embedded in the game and provide players with an opportunity to continue learning outside the game if they are interested.

Minigames provide a real-time opportunity to improve self-efficacy through adaptive skills such as decision-making and refusal skills that are relevant for avoiding opioid misuse. In *Risk Sense*, the player is tasked with working to prevent risks (impulsivity, ignorance, and relationship problems). By playing *Risk Sense*, players become aware of the risk factors for opioid misuse. In *Stress Sense*, players have an opportunity to practice cognitive reframing, a cognitive behavioral strategy [86] to address thought distortions (all or none, catastrophizing, and should statements) and seeing a particular problem in a different light that serves to reduce the emotional distress that can increase the risk of opioid misuse [86]. In addition to cognitive reframing, players learn several coping strategies, including exercise, talking to trusted adults, watching movies and music, reading, taking time off to rest and relax, sleeping well, and using distraction techniques to take the mind of stressful thoughts. In *Refusal Power*, the player helps the character resist peer pressure to engage in risky behaviors. In a *Social Media Game*, through posts on social media, players practice advocating for behaviors that deter drug misuse, encourage help seeking from trusted adults and mental health professionals, and support peers who are struggling. In *Choice Power*, players learn to communicate effectively with others to get the help they need or to avoid getting into trouble. In *Know Power*, players learn facts about opioids and opioid misuse through conversations with other nonplayer characters. *Choice Power* and *Know Power* are embedded within each storyline, whereas the other minigames are shown on the homepage (Figure 1).

Figure 1. The home page of the *PlaySmart* video game on the left and a screen from the *Stress Sense* minigame on the right. Licensed under Creative Commons 4.0.

The final version of *PlaySmart* is a web-based video game that is accessible to any device that can access the internet and has a browser. User data were stored in an SQLite database hosted on the Amazon Web Services. Data on players' progress in the game, such as what game levels have been completed and how many minutes were spent on the game, can be downloaded securely from the database.

Playtesting

Informed by user-centered design principles, the feedback obtained during playtesting was critical in modifying *PlaySmart* for its final form. Following the initial iteration of the game, participants were recruited to play the game. Participants generally agreed that the game was straightforward, engaging, and provided a wealth of information on opioid use and misuse. Feedback from these groups primarily consisted of recommendations for technical changes related to minigames, content of the text, or gameplay mechanics. For example, some of the feedback identified content in the game that was not relatable to adolescents and provided specific suggestions for how to improve it. Some felt that the initial set of avatars did not include enough variation to reflect a diverse group of adolescents. The use of avatars that players can relate to is critical because evidence indicates that players exhibit a higher sense of responsibility and attachment to avatars that look like them [87] and are more engaged when using avatars that look like them [88]. Some felt that some minigames needed a tutorial to orient the player. Some adolescents felt distracted by the background music and suggested a way for adolescents to modify the sound based on personal preference. Some players felt that some parts of the risk-sense minigame were not demanding, resulting in the addition of more tasks in the minigame that increased the challenge posed in the game. Other players felt that nonplayer characters in the game were too knowledgeable in contrast to their friends in real life. This feedback informed the modification of the game such that chats more realistically depicted the balance between friends who may be informed and others who may not be informed about facts relating to opioids. We used this feedback to improve the final version of the game alongside the game developers [89] (Figure 1). Through this testing, we solidified our procedures for the RCT.

Preimplementation

Participants from our preimplementation focus groups shared the potential barriers and facilitators to implementation as well as information specific to motivation around gameplay and engagement with the intervention. SBHA adult affiliates mentioned the importance of administrative buy-in before implementing *PlaySmart* in schools and clinical settings. They also provided examples of possible ways to engage youth with the game, such as through academic incentives, making it an activity in and of itself in schools, or implementing it as part of the process of visiting a clinic (eg, in the waiting room of a clinical setting). Youth from the preimplementation focus groups generally agreed that it could be used in their school community as an interactive way to learn, and most of their first impressions highlighted several positives of the *PlaySmart* game. For example, they spoke about liking the comic-book style of the game, the relatability of each storyline, and the interactive components of the storylines and minigames. They highlighted the importance of training both staff and students to equip them with the necessary troubleshooting skills and to ensure that they understand their rights to confidentiality and data privacy. Much of the discussion regarded optimal strategies for game delivery, and many participants believed that integrating *PlaySmart* into existing structures such as health classes, clinics, or school clubs would gain the best traction from both students and staff. Focus group participants emphasized the value of incentives for implementing the game in schools, especially because it was a new program and required some human resources to implement effectively. Common suggestions for greater incentives include promoting *PlaySmart* through social media youth ambassadors, incorporating gamification elements (eg, leaderboards or communication channels), and framing it as a novel health behavior tool rather than a more traditional form of prevention-based education. This information was used to create *PlaySmarts* educator’s manual, which was shared with implementation partners as a resource.

Discussion

Background

The public health impact of concurrent opioid and mental health crises cannot be overstated and underscores the need for innovative approaches for engaging adolescents and young adults in preventive interventions. Given these crises, and with support from the National Institutes of Health HPC Initiative, we developed a novel video game intervention to prevent opioid misuse among older adolescents. This is the first video game intervention to address opioid misuse and mental health issues among older adolescents. Existing game-based interventions for opioid misuse have focused on younger adolescents [52] and on addressing knowledge gaps [51,52], increasing the perception of risk of harm from opioid misuse [51], improving decision-making [52], changing attitudes [51] and beliefs, and improving self-efficacy [51]. We highlight the need to address mental health as well as the significant role that underlying mental disorders play in increasing the risk for opioid misuse, address stigma, confront existing myths associated with mental health problems, and underscore the importance of addressing seeking treatment for mental disorders in addition to substance misuse.

Our formative work revealed that mental health and its connection to opioid use were among the most prevalent themes that arose from the youth focus groups. Preexisting mental health problems such as depression can increase the likelihood of substance misuse, including opioids [7-9]. In addition, the stigma surrounding access to mental health services can be a barrier to early engagement in treatment. Serious video games, such as *PlaySmart*, offer an engaging way to prioritize mental health as a central focal point by empowering adolescents to be vocal and intentional about asking for help and by breaking down myths that mental health support is ineffective or worsens symptoms. In *PlaySmart*, the risk of opioid misuse driven by underlying mental health problems is woven throughout the game, while normalizing help seeking and adaptive coping strategies. To examine the impact of incorporating mental health factors into *PlaySmart*, our ongoing RCT will also assess the impact of *PlaySmart* on mental health outcomes.

In contrast to other game-based interventions to prevent opioid misuse [51,52], and consistent with our standard practice, we engaged our target audience of adolescents as cocreators in the process, and they were involved throughout the development and playtesting of *PlaySmart*. Involving the end user increases the likelihood of relatable storylines and provides an opportunity to improve the game based on player feedback [72,73]. Most of the youth who partook in the focus groups had not previously had education focused on opioid misuse, highlighting an existing gap in the current school curriculum while also demonstrating the need for this game to adequately address. In addition, important avenues through which adolescents learn incomplete information about drugs, such as music, media, or celebrities, are directly addressed in the game.

Our youth focus groups had good racial representation, including youth identifying as Asian, Black, White, and mixed race, in contrast to a similar study focused on opioid misuse prevention among adolescents [81]. However, representation from adult representatives was predominantly White, which mirrors the racial ethnic distribution of teachers [90,91] and health care workers [92] in the United States. Further evaluation following the completion of the RCT will explore whether there were any differences in the efficacy of response among different racial and ethnic groups.

Creating evidence-based interventions without a plan for real-world implementation can negatively impact effectiveness [93]. Our preimplementation work revealed ways to facilitate the uptake of *PlaySmart* in school settings, such as incorporating the video game into existing structures, such as a health class, which would allow for greater feasibility. Other suggestions for wide-scale uptake identified from preimplementation focus groups include making *PlaySmart* available through social media or as an intervention for adolescents waiting at an outpatient clinic, particularly if these measures are incorporated into existing clinic workflows.

Video games are very engaging and universally used by adolescents and young adults. Consequently, they offer an innovative way to deliver evidence-based prevention interventions that can potentially be lifesaving. In addition, the *PlaySmart* video game is a mobile web-based intervention that can be accessed repeatedly by a player through their phones, tablets, or computers, and can be delivered anywhere with internet access. Through this formative work, we demonstrated the feasibility of engaging a comprehensive group of stakeholders (eg, adolescents with and without opioid misuse, prevention scientists, addiction medicine providers, and school representatives) in developing a compelling video game and using user-centered design principles [71,72] in both the development and initial testing of the intervention. Informed by our focus group and interview participants and guided by user-centered design principles, we translated behavior change theories, specifically the health belief model, theory of planned behavior, and social cognitive theory, into relatable storylines and minigames. Through these game components, adolescents acquire accurate knowledge and perceptions of the risk of harm from opioid misuse, learn about the benefits of addressing mental health issues, and practice a range of critical skills around refusing invitations to misuse drugs, practicing cognitive reframing when stressed, and using coping strategies and mental health resources.

Limitations

During this formative work, specifically during playtesting, we had to switch from in-person procedures in schools to web-based procedures because of the COVID-19 pandemic. This occurred during playtesting and affected recruitment and retention during the playtesting sessions. As a result, we had only one group of participants (n=3) who played the entire game and were able to complete *quantitative* assessments of knowledge of opioids, perception of risk of harm, and gameplay experience. As such, we were unable to provide *quantitative* summary data on whether there was improvement in knowledge about opioids or perception of risk of harm from opioids in this formative evaluation. In the ongoing RCT, we are evaluating improvements in opioid knowledge and perception of the risk of harm from opioids (primary outcome) and will provide these results following the completion of the RCT. Only 1 participant with OUD participated in this study, which may have impacted the video game content, although this is a preventive intervention primarily targeting adolescents without opioid misuse. Although we assessed factors that would impact usability and engagement during gameplay, the questions did not specifically assess whether adolescents would be motivated to play the game. We are currently assessing factors that would influence motivation in ongoing RCT. Future formative work can assess the factors that can influence motivation, which may influence the final game design. We assessed how familiar adolescents were with video games during the focus groups, but we did not assess perceptions of the game between those who were hard-core gamers and those who were not, which may have informed game design to have the broadest reach across different levels of gamers. Future formative studies on game development should include this information.

Conclusions

The ongoing dual opioid and mental health epidemics underscore the need for effective prevention interventions that can engage adolescents and address accurate information and skill-building in these areas. Video games provide an appealing medium to engage adolescents while translating evidence-based theories into a digestible, easily accessible format that allows for repeated practice of behaviors necessary to prevent opioid misuse and promote mental health in adolescents in real-world settings. Engaging the target audience and other key stakeholders in the development and testing of this digital health intervention ensures that it reflects their voices and perspectives for the greatest impact and reach.

Acknowledgments

This manuscript was made possible by the National Institute on Drug Abuse (NIDA) Helping to End Addiction Long-term (HEAL) award 1UG3DA050251-01, NIDA Diversity Supplement award UH3DA050251-031S1, Doris Duke Charitable Foundation award 20220145, and the Yale Center for Clinical Investigation Clinical and Translational Science Awards Program award UL1 TR001863 and KL2 TR001862 from the National Center for Advancing Translational Sciences. The authors would like to thank Ben Sawyer and Schell Games for their technical support in the game development.

Data Availability

We have provided our focus group guide, synthesized results from the focus group analysis, and questions used during the playtest. Owing to the sensitive nature of the data from the focus groups, including the presence of potentially identifiable information, we cannot share the data from the focus groups.

Authors' Contributions

CSFF, TMP, and LEF were involved in the conceptualization. CSFF developed the focus groups and interview guides. CSFF and TMP were involved in individual interviews, focus groups, and thematic analyses. KA, CSFF, LAH, CS, TMP, and LEF were involved in the interpretation of study findings. KA, CS, and LAH drafted the manuscript. All authors have reviewed, edited, and approved the final draft of the manuscript.

Conflicts of Interest

LEF is the founder and on the Board of Directors of a Yale company, Playbl, which distributes game products. The other authors have no conflicts of interest to declare.

Abstract

Background: The global percentage of older people has increased significantly over the last decades. Information and communication technologies have become essential to develop and motivate them to pursue healthier ways of living. This paper examines a personalized coaching health care service designed to maintain living conditions and active aging among older people. Among the technologies the service includes, we highlight the use of both gamification and cognitive assistant technologies designed to support older people and an application combining a cognitive virtual assistant to directly interact with the older person and provide feedback on their current health condition and several gamification techniques to motivate the older person to stay engaged with the application and pursuit of healthier daily habits.

Objective: This pilot study aimed to investigate the feasibility and usability of a gamified agent-based system for older people and obtain preliminary results on the effectiveness of the intervention regarding physical activity health outcomes.

Methods: The study was designed as an intervention study comparing pre- and posttest results. The proposed gamified agent-based system was used by 12 participants over 7 days (1 week), and step count data were collected with access to the Google Fit application programming interface. Step count data after the intervention were compared with average step count data before the intervention (average daily values over a period of 4 weeks before the intervention). A 1-tailed Student *t* test was used to determine the relationship between the dependent and independent variables. Usability was measured using the System Usability Scale questionnaire, which was answered by 8 of the 12 participants in the study.

Results: The posttest results showed significant pre- to posttest changes (P=.30; 1-tailed Student *t* test) with a moderate effect size (Cohen d=0.65). The application obtained an average usability score of 78.

Conclusions: The presented pilot was validated, showing the positive health effects of using gamification techniques and a virtual cognitive assistant. Additionally, usability metrics considered for this study confirmed high adherence and interest from most participants in the pilot.

Introduction

We are currently witnessing an increase in the world's population, which is also growing older. According to United Nations' World Population Ageing Report [1], the global population aged 65 years or older was 727 million in 2020 and is expected to reach over 1.5 billion in 2050. With the increase in the number of older citizens living in today's society, there has been a growing necessity to research and develop assistive technologies that can support older people [2,3], especially in intelligent environments [4,5]. Among the already available technologies, we highlight the use of gamification and cognitive assistants in this context.

Gamification refers to enhancing services with features that can offer "gameful" experiences to their users and keep them motivated and engaged, increasing their activity, social interaction, and the quality and productivity of their actions [6]. In other words, gamification can be seen as improving applications developed for serious contexts using game-like features that can potentiate user experience and motivate and encourage the user to pursue desired behaviors.

Companies are extending (and gamifying) their existing services, and more investments are being made in developing gamified applications and serious games [6]. Likewise, recent research has led to advancements in gamification and serious games in health care [7-10] with great focus on different health domains, such as promoting both physical and cognitive activity [11-23], promoting behavioral changes [7,24] and providing personalized health care services at all ages [25]. These services can bring innovative and cost-effective solutions and treatments to the most fragile and isolated groups in our society, such as older people and those with chronic diseases [14,26]. Furthermore, personalization becomes essential for these kinds of services, as individual necessities and capabilities are even more impactful to this age group. The lack of personalized mechanisms could lead to quick loss of interest in using the health care service. In elderly care, this could easily result in the deterioration of health conditions.

Cognitive assistant research and development has seen significant advances in the literature over the last decade. Cognitive assistants can be endowed with social and emotional processing [27,28] to interact with humans and improve their capabilities while not replacing them in specific tasks. In a more formal definition, cognitive assistants can be described as intelligent mechanisms that interact and learn with the user and can provide adequate feedback to improve behaviors that otherwise would be difficult to accomplish. As such, cognitive assistants will augment human intelligence and assist in decision-making and action-taking [29]. In recent years, exciting approaches have been proposed targeted toward elderly care to enhance the daily lives of older people and improve both their cognitive and physical capabilities.

In sum, the development of intelligent mechanisms and algorithms to adjust the interaction and support provided to the older person, including serious games with a scalable difficulty as well as robots that play games and communicate with older people using different emotions, is fundamental to ensure interactive and personalized systems that are tailored to each user [30].

Existing research on combining the use of a gamified application with the use of a virtual cognitive assistant for the context of elderly care is still lacking. According to a previous study [31] and most recent proposals in the literature, the majority of the available approaches using some kind of assistant either consider the use of a physical robot or a virtual companion (usually a pet) to interact with the older person; neither approach considers the user's progress as a variable in their design. As a result, these approaches cannot follow the evolution of the user over time and are most frequently used for one-time interactions. Because of that, they can represent user progress in adopting improved, healthier behaviors only in a very limited way. Therefore, the major novelty proposed in this work is a cognitive virtual assistant that can take advantage of the outcomes of a gamified health care application. Such an assistant can not only react emotionally to the user's progress (in terms of achieved health goals and challenges) but also learn how to interact and improve the feedback provided to them by learning their behaviors, interests, and current capabilities. In this regard, we studied the use of processes to provide feedback and rewards to the older person, make it possible to increase the cognitive and physical load as the user becomes more proficient with the system, and adopt methods that enhance and promote social interaction, which can result in more personalized elderly care solutions. Furthermore, adapting the support provided to the older person according to their interests, capabilities, and necessities, as well as the surrounding environment, will improve health and well-being, capture interest and ensure positive engagement, facilitate social interaction, and decrease the impact of many medical conditions.

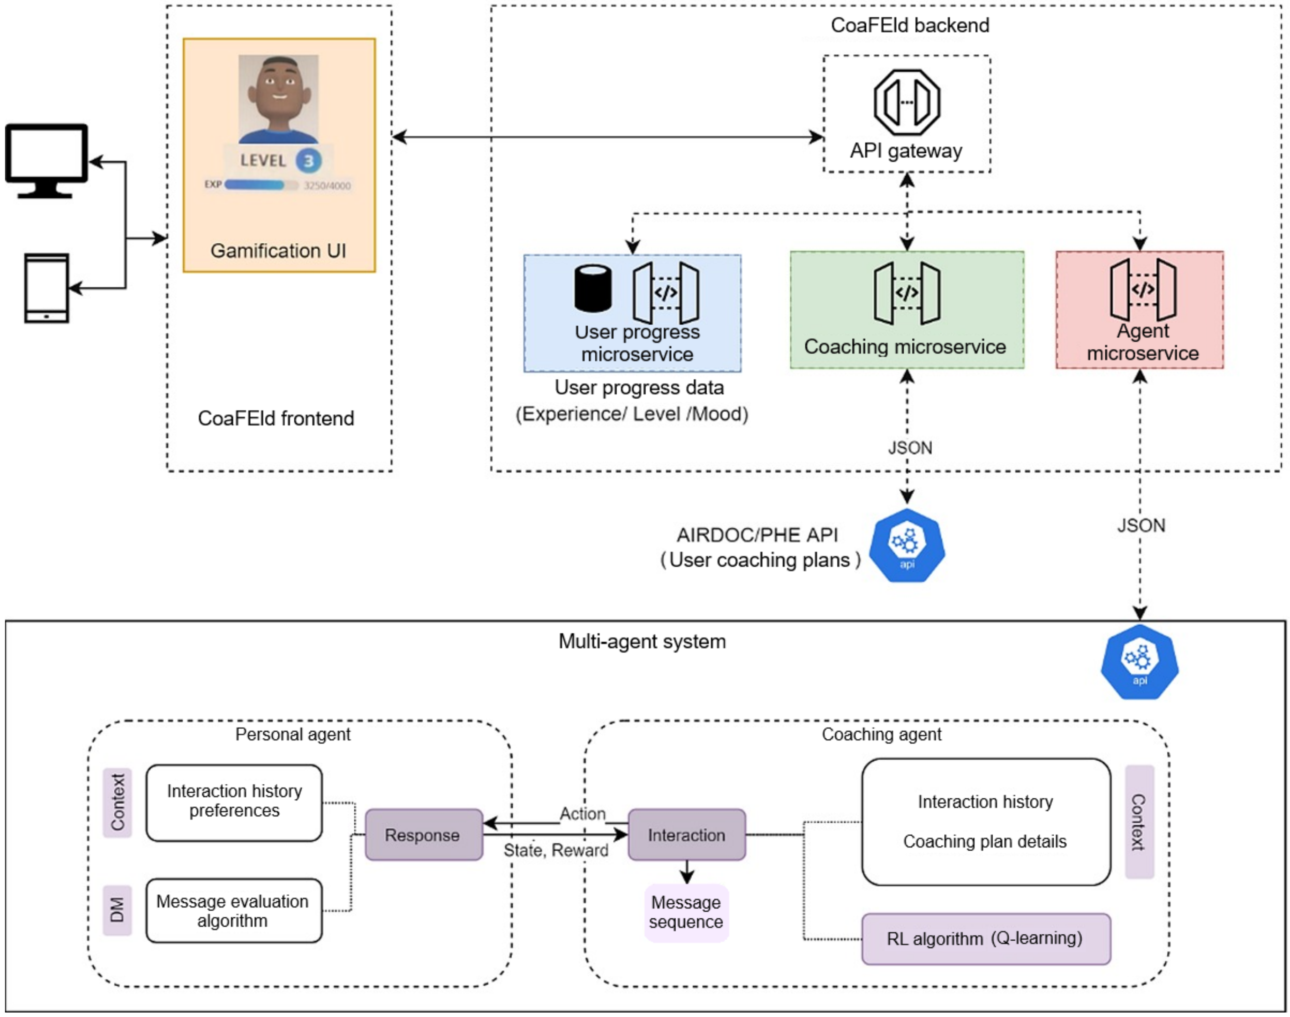
Considering all these ideas, this study aims to perform an initial validation to compare outcomes after using a health care application developed for older people named CoaFEld (Coaching for Elderly) and to determine its overall acceptability and usability after the experiment period is completed. For this, we chose user step count data as the primary outcome. We formulated a hypothesis through a paired 1-tailed Student *t* test to compare step count data obtained before and after the intervention.

Methods

CoaFEld System Design

CoaFEld was developed following a microservice-oriented architecture (Figure 1), divided into 3 main components: a user web application, an application programming interface (API) gateway, and a set of microservices. These microservices communicate and store specific user information regarding user progress while using the application (using different gamification components), health status (derived by the performance of established coaching plans), and user interactions with the feedback that is provided to the user (personalized message interactions based on user preferences).

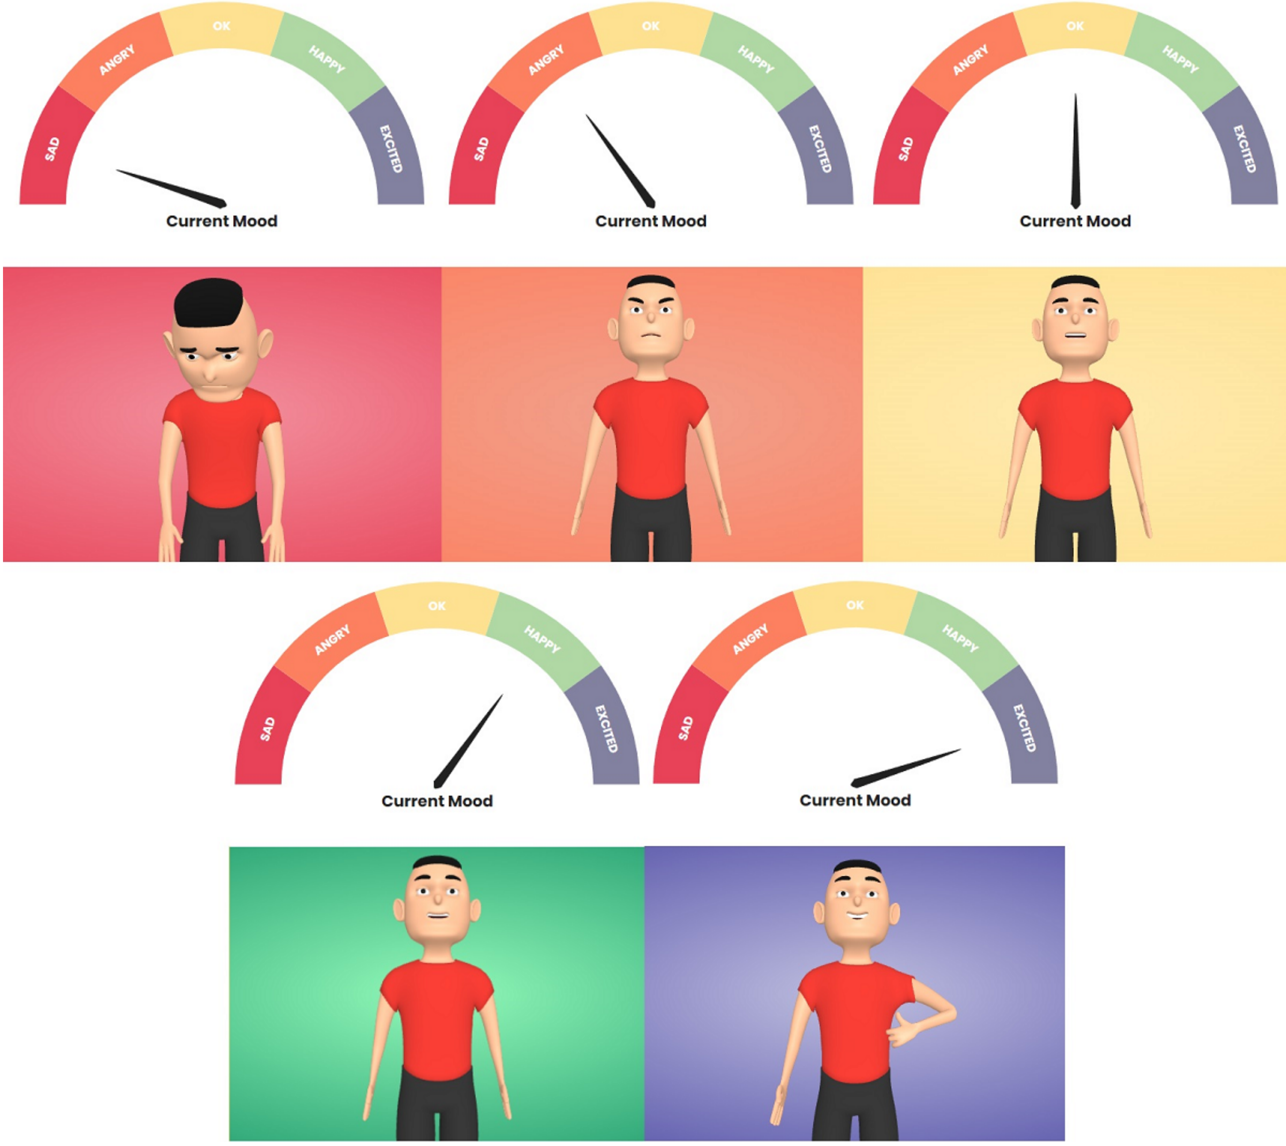
Figure 1. The proposed coaching system architecture reproduced from Martinho et al [30] which is published under Creative Commons Attribution 4.0 International License [32]. AIRDOC: Aplicação móvel inteligente para suporte individualizado e monitorização da função e sons respiratórios de doentes obstrutivos crónicos; API: application programming interface; CoaFEld: Coaching for Elderly; DM: decision making; RL: reinforcement learning; PHE: personal health empowerment; UI: user interface.



The coaching application that has been developed is gamified with consideration of the main findings of Martinho et al [31], who reported the most successful gamification techniques in the context of elderly care. These techniques include features such as experience or levels and points as the system's currency to unlock new content. Additionally, the developed application presents a cognitive virtual assistant with different emotional queues depending on the positive or negative progress of older people as players and users of the coaching application. Following Martinho et al [30], the current emotional state shown by the cognitive assistant is based on all coaching plans assigned to that user and an evaluation of the number of goals that have been successfully achieved by that user vs the total number of goals in the coaching plan. The details of these plans are described in more detail in our previous work [33].

We consider 5 main emotional states to represent user progress (Figure 2). These emotional states were inspired by Russell's [34] circumplex model of affect, which is based on 2 dimensions (arousal and valence) and is ranked according to degree for both of these dimensions.

Figure 2. Representation of the 5 different emotional states of the cognitive assistant reproduced from Martinho et al [30] which is published under Creative Commons Attribution 4.0 International License [32].



(1) The "sad" or "depressed" emotions are the most negative (with negative degrees for both arousal and valence); (2) "angry" represents the second most negative emotion (with a positive degree for arousal and a negative degree for valence); (3) the "OK" or "calm" emotions are moderate (with a negative degree for arousal and a positive degree for valence); (4) "happy" represents the second most positive emotion (with a neutral degree for arousal and a positive degree for valence); (5) "excited" represents the most positive emotion (with positive degrees for both arousal and valence).

An API gateway was developed in the proposed work with the main goal of encapsulating a set of several microservices and providing an API specific for each client (thus serving as a single entry point into the system). It is also the responsibility of the API gateway to include authorization and authentication functionalities and assure asynchronous communication between the requests sent to the available microservices. Three microservices have been developed to store and provide information related to both user progress and health outputs:

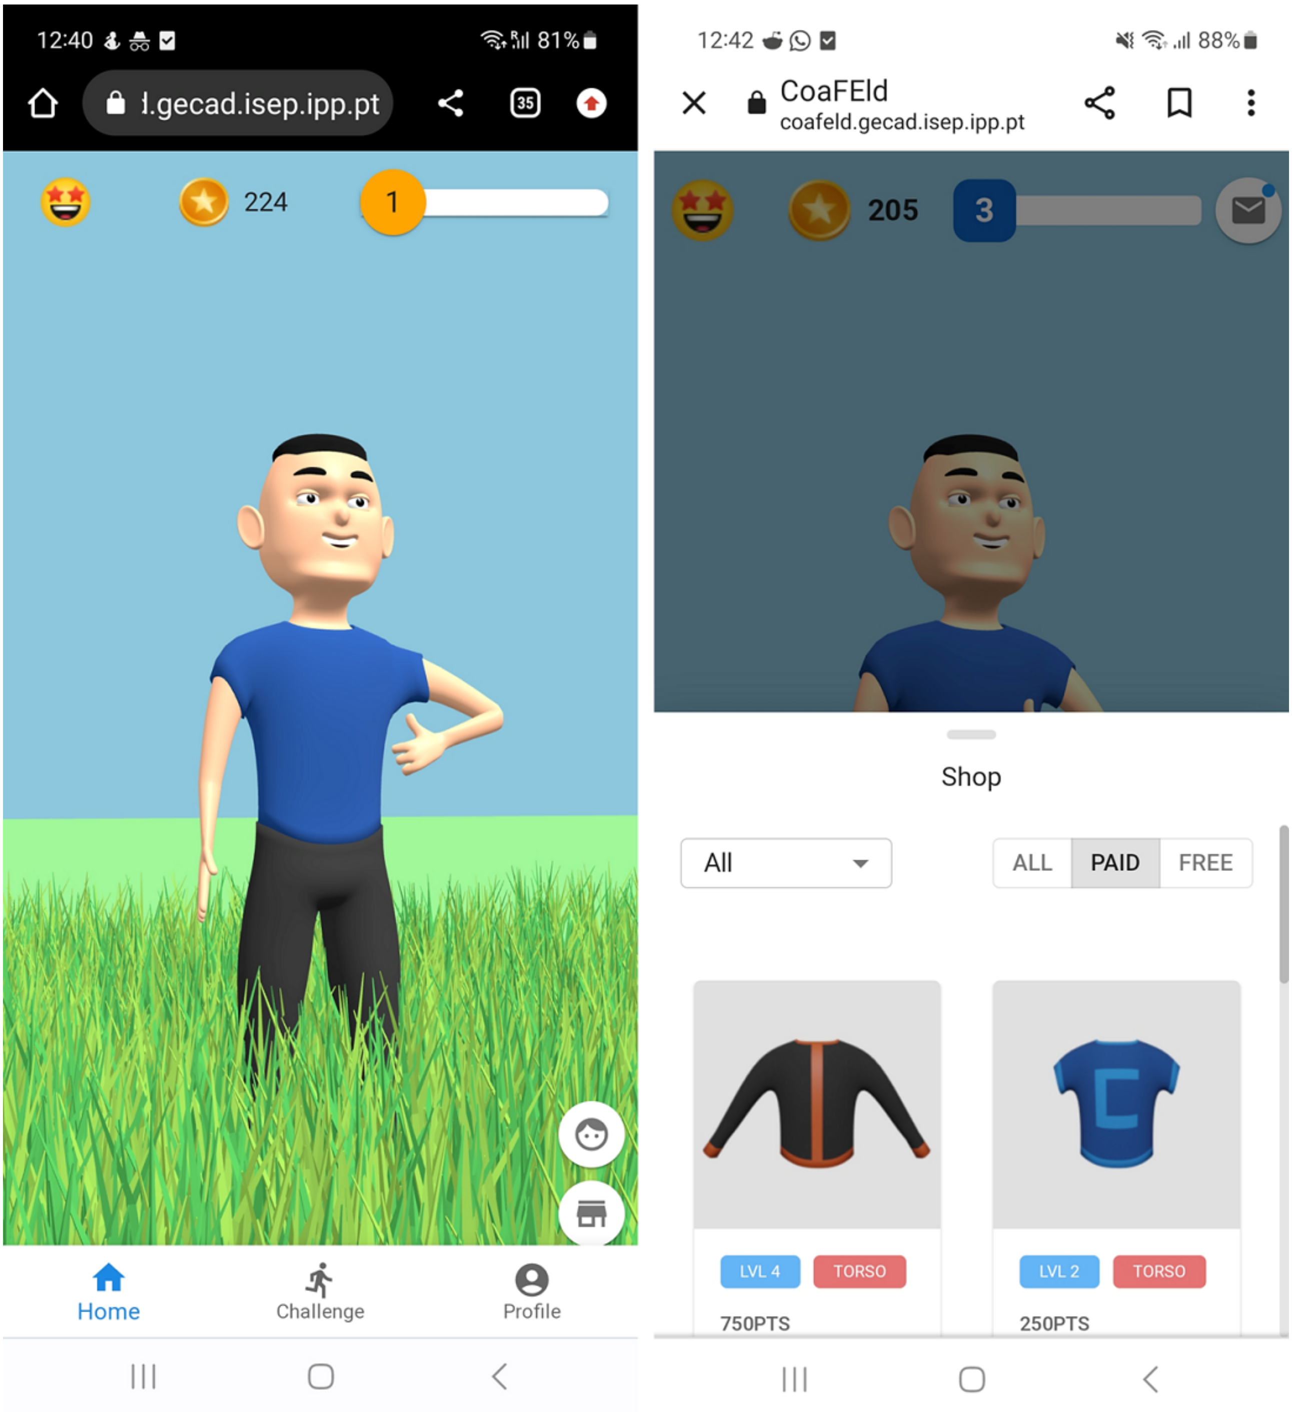
The "user progress" microservice manages data related to user progress and actions within the coaching application, including all the information on current game experience, level, and points; unlocked content; in-game purchases; cognitive play session results; and virtual assistant configurations and emotional state. The "coaching" microservice, developed by Martinho et al [33], is a generic mechanism to configure and evaluate coaching plans with health-related goals that can be dynamically updated with increasing or decreasing difficulty depending on the user's performance. The "agent" microservice, developed by Martinho et al [35], uses a personal agent that returns the interaction (message queue) to be sent directly to the user and evaluates the feedback provided by the user and a coaching agent that applies reinforcement learning to understand what interactions should be next sent to the user at specific moments of the day based on previous interactions with that user.

Mobile Interface Design

The CoaFEld application was developed to establish an environment where users can improve different aspects of their daily lives. In this preliminary validation, the study focused on accessing the user's current physical condition, specifically daily step data, which is retrieved from the Google Fit API (after the user grants permission to access this information). After this, daily step challenges are proposed to the user based on the number of steps they have taken weekly. Multimedia Appendix 1 shows the algorithm used to combine the step data information retrieved from the Google API.

One of the most important features available in the application is the home interface with the virtual assistant, which interacts with the user (Figure 3). The application incorporates various gamification techniques. First, the emoji located in the top left corner serves as a visual representation of the user's emotional feedback (according to the virtual assistant's current emotional state), indicating positive or negative progress throughout app use. Second, the star coin shows the points earned upon completion of daily challenges, which can be used to exchange and unlock content available in the store, such as clothing items. This feature improves the relationship between the user and the virtual assistant with individual character customization. Third, the blue progress bar, also shown on the screen, represents the user's earned experience points (XP) and their corresponding level within the application. This visual representation allows users to track their progress and observe their evolution as users of the application.

Figure 3. Home interface showing the virtual assistant and gamification components.



The application also includes a Challenge screen (Figure 4) for the user to see their current goals and daily performance, showing the overall progress achieved on each day along with a detailed breakdown of the user's performance, including aspects such as more and less active hours during the day, points, and experience to be acquired.

Finally, in the Profile screen (Figure 5), the user can access the virtual assistant profile, including purchased items, completed challenges, and emotional progress, creating a way to track the user's progress and achievements.

Figure 4. Challenge interface showing the user's daily performance.

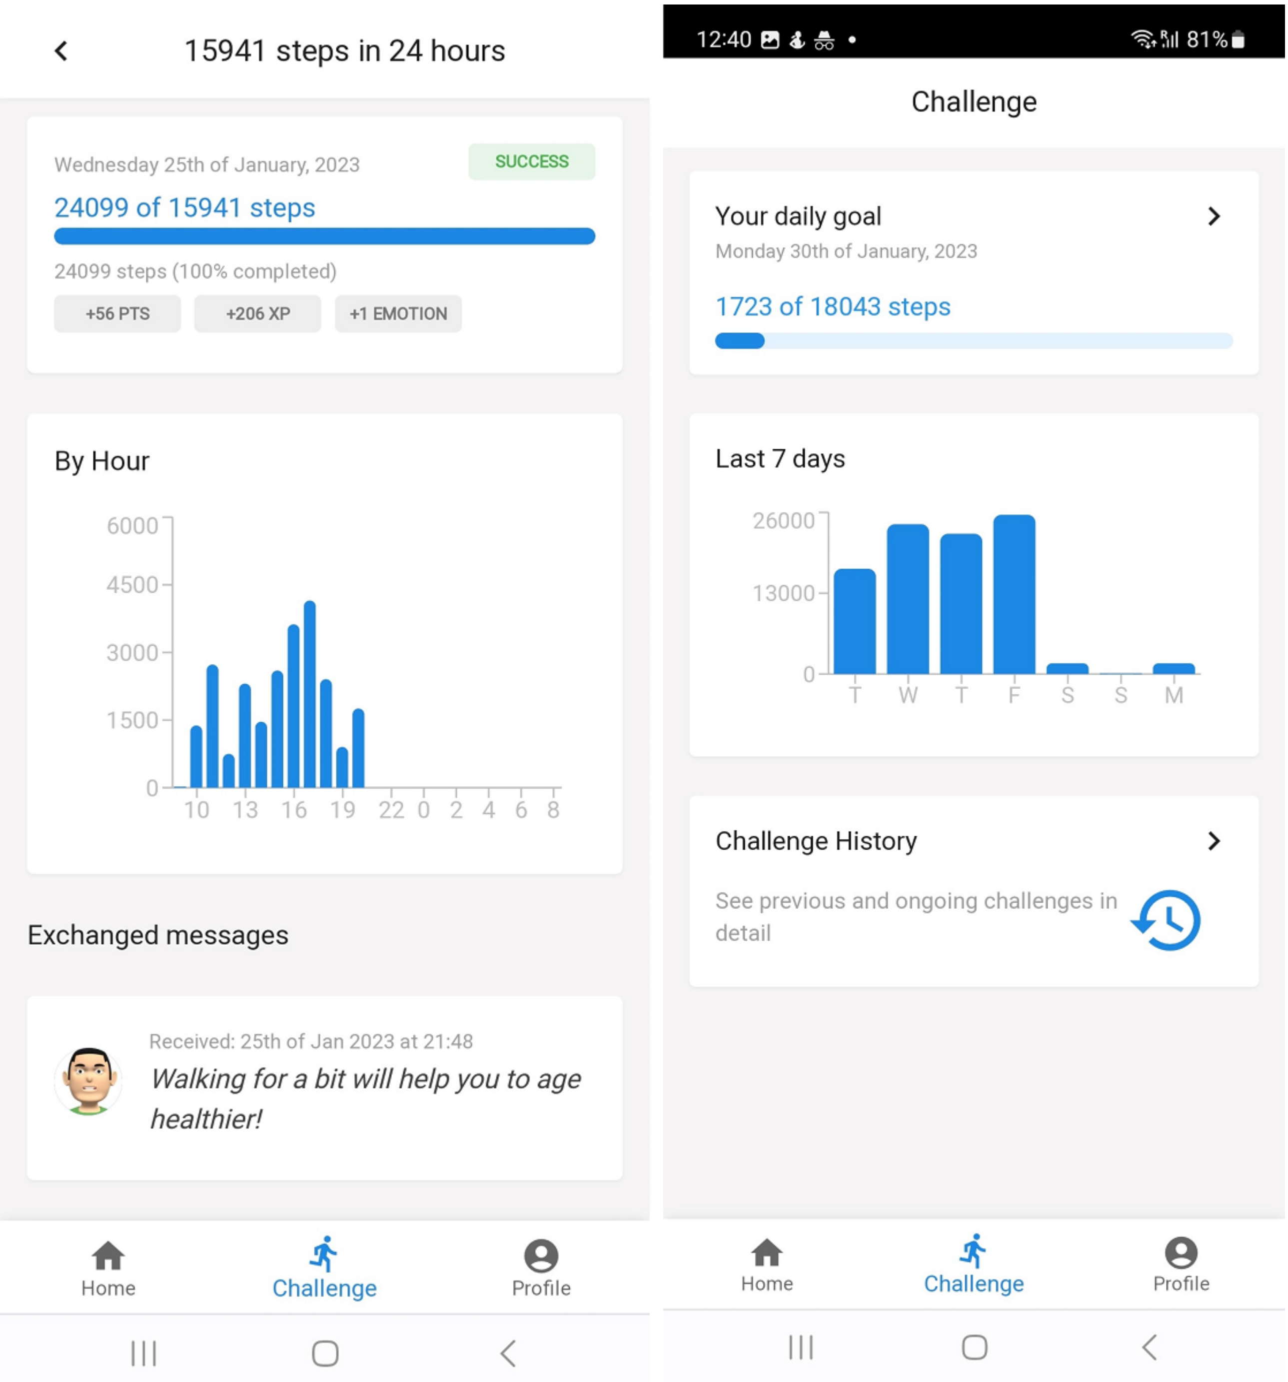


Figure 5. Challenge interface showing the virtual assistant progress.

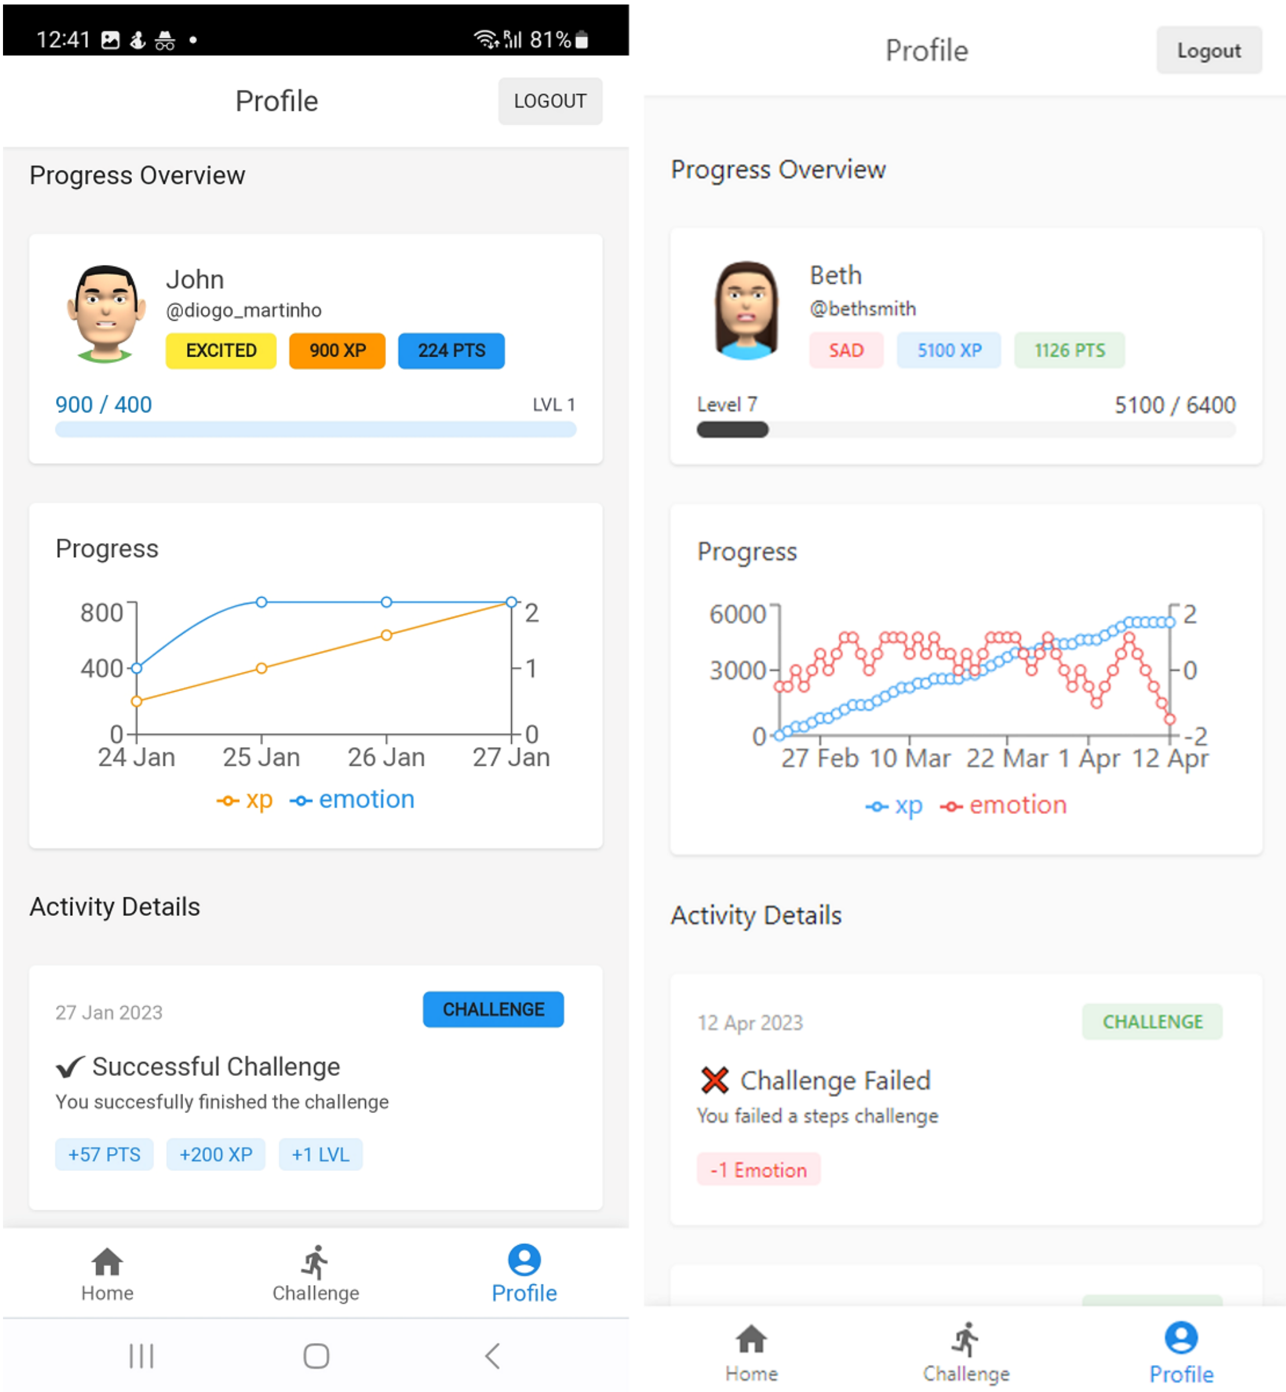

Recruitment

The eligibility criteria for participants to enroll in the study were a minimum age of 55 years and an active Google Fit account. We initially recruited 16 participants. However, 3 users dropped out due to smartphone incompatibility with the Google Fit app and 1 due to not having Google Fit data past study enrollment. As a result, the proposed gamified agent-based system was used by 12 participants with a median age of 62 (IQR 12.5) years over 7 days (1 week), and step count data were collected with access to the Google Fit API. Step count data after the intervention were compared with average step count data before the intervention (average daily values over a period of 4 weeks before the intervention). A paired 1-way Student *t* test was used to determine the relationship between the dependent and independent variables. The null hypothesis ($H_0 \leq 0$) and the alternative hypothesis ($H_1 > 0$) were established by comparing the difference between pre- and posttest step count values.

Questionnaires

After completing the study, each participant was requested to fill out the System Usability Scale (SUS) questionnaire to provide feedback regarding their overall user experience during the period of experimentation.

Ethical Considerations

No ethics approval was applied for. All participants had access to the data privacy statement with information on data privacy, storage, access, and use within the study, to which they agreed before joining the study. User data were collected according to the permissions each user provided with the use of the Google Fit API. The study was performed according to the privacy policy and policy for the acceptable use of technologies of information and communication of our institution (Polytechnic Institute of Porto). The study was designed as an intervention study comparing pre- and posttest results and was conducted according to the principles of the Declaration of Helsinki and following the General Data Protection Regulation.

Results

Statistical analysis was performed using an Excel (Microsoft Corp) data analysis toolkit for *t* tests paired with 2 samples for the means method. Step count data were compared for the average of 7 days of experimentation with the average step count data of each corresponding day for the 4 previous weeks (28 days total; average 4 days for each 1 corresponding day).

The step counts were significantly higher after the intervention than before the intervention (mean 4931, SD 5056 steps vs mean 2532, SD 2049 steps and median 3826, IQR 5343 steps vs median 2169, IQR 4888 steps). These data were statistically significant at a 95% confidence level (P=.03; Student *t* test). The measured effect size (Cohen *d*) for paired samples according to was 0.65, which is between moderate (effect size >0.5) and large (effect size >0.8).

Looking at average daily differences (Table 1), it is possible to observe a positive difference on all days, with a slight decrease on the third day of the study, which can be explained by the fact that the highest virtual assistant emotional state is achieved after completing 2 daily challenges, starting from the baseline emotional state (0), and on the third day the emotional state no longer improves after successful completion of challenges. Despite this, by establishing a mechanism to reward users with enough points by allowing them to unlock additional content after 5 to 6 days of correct goal completion, it is possible to observe a significant increase in the average daily step count on the last 2 days of the experiment. The last 2 days have the highest average daily difference in step count between pre- and posttest, indicating a positive improvement as the experimentation period continues.

Table 1. Average daily difference between step count data before and after the intervention.

Day	Steps, n
1	2572
2	2138
3	975
4	1861
5	1547
6	3031
7	3178

Regarding usability, 8 of the 12 participants completed the SUS questionnaire, which comprises 10 questions, with response options ranging from “strongly agree” to “strongly disagree,” to measure the usability of software, mobile devices, websites, and applications. The answers are then normalized to obtain a usability score to describe the evaluated product. In the case of the developed application, after accessing all the answers provided by the users, we calculated an average usability score of 78 (on a scale of 0-100), corresponding to high usability. Participants were also asked to provide additional comments regarding their experience while using the CoaFEld application, and the overall comments were positive, with only a few suggestions to improve the login interface (since there was no “recover my password” feature implemented and the users were logged off the application automatically after each day).

Discussion

Principal Findings

As the world population grows older, it becomes essential to study and develop new personalized health care services that can support older people and promote healthier and active aging. As observed in various studies, different solutions are already being developed that take advantage of intelligent engagement strategies to interact with, persuade, and motivate older people to pursue more positive behaviors in their daily lives. In this context, gamification to enhance traditional health care services, especially when supporting older people, has already been shown to be a strong approach that can provide many advantages that contribute to improved health behaviors.

This study used the CoaFEld application, previously introduced by Martinho et al [30], which was developed with the main goal of supporting older people and offering different functionalities to motivate and persuade them to follow healthier lifestyles. This application includes gamified elements to motivate and enhance user experience, as presented in the design section of this paper. It includes a virtual assistant to interact with the older person and provide feedback on the progress in their health. As was also explained, different emotional states representing the user’s progress are shown, which improve as the user achieves health goals or worsens if they do not.

In our study, we validated the impact of the virtual assistant and the overall gamified solution developed for the CoaFEld application with the participation of users aged 55 years or older. We obtained significant results regarding the approach’s usability, acceptability, and effectiveness. More specifically, our study supports the importance and positive effect of combining gamified elements and a social engagement strategy with a virtual assistant to achieve user progress in a health care setting. The results favor the use of the CoaFEld app, with improved health outcomes after the intervention when compared to the health data obtained before the intervention (P=.02, calculated with the Student *t* test when P<.05) with a Cohen *d* effect size of 0.77, which is moderate yet close to large (ie, effect size >0.8). Additionally, the results of the SUS questionnaire confirmed high acceptability and usability, with an average usability score of 78 along with overall positive comments from the participants, expressing their intentions to keep using the application after the intervention period was completed.

Limitations

Two main limitations were observed during this validation study. The first limitation relates to the sample size, since 12 participants was an insufficient number to cover all older age groups. As explained in a previous section of this paper, the median age was 62 years, with the oldest participant being aged 70 years. However, as all the users who participated in this study were aged between 55 and 70 years, we can confirm the success of the intervention within this age group. Another limitation was related to the intervention period. For the intervention, participants were asked to use the CoaFEld application for 1 week and, as observed, this allowed us to obtain positive results. However, these results can only confirm a short-term improvement, and a more comprehensive, long-term study is necessary in light of the results obtained in this study.

Conclusions

Our findings highlight the use and importance of new, intelligent tools and methods to provide personalized support to promote healthier and more active aging among older people. In this context, different engagement strategies have been studied to motivate older people to adopt healthier lifestyles, which include gamifying more traditional health care applications targeted at this age group. These ideas are considered in this study, and a health care service for older people is presented and validated, showing the positive effects of gamification techniques and a virtual cognitive assistant that can enhance the user experience, encourage progress, and provide feedback. Additionally, usability metrics considered for this study confirmed most participants' high adherence and interest.

Further studies need to be performed on the effectiveness of this approach among older people and to measure the long-term performance of the developed service.

Abstract

Background: Stroke management in rural areas is more variable and there is less access to reperfusion therapies, when compared with metropolitan areas. Delays in treatment contribute to worse patient outcomes. To improve stroke management in rural areas, health districts are implementing telestroke networks. The New South Wales Telestroke Service provides neurologist-led telehealth to 23 rural spoke hospitals aiming to improve treatment delivery and patient outcomes. The training of clinical staff was identified as a critical aspect for the successful implementation of this service. Virtual reality (VR) training has not previously been used in this context.

Objective: We sought to develop an evidence-based VR training module specifically tailored for stroke telehealth. During implementation, we aimed to assess the feasibility of workplace deployment and collected feedback from spoke hospital staff involved in stroke management on training acceptability and usability as well as perceived training impact.

Methods: The TACTICS VR Stroke Telehealth application was developed with subject matter experts. During implementation, both quantitative and qualitative data were documented, including VR use and survey feedback. VR hardware was deployed to 23 rural hospitals, and use data were captured via automated Wi-Fi transfer. At 7 hospitals in a single local health district, staff using TACTICS VR were invited to complete surveys before and after training.

Results: TACTICS VR Stroke Telehealth was deployed to rural New South Wales hospitals starting on April 14, 2021. Through August 20, 2023, a total of 177 VR sessions were completed. Survey respondents (n=20) indicated a high level of acceptability, usability, and perceived training impact (eg, accuracy and knowledge transfer; mean scores 3.8-4.4; 5=strongly agree). Furthermore, respondents agreed that TACTICS VR increased confidence (13/18, 72%), improved understanding (16/18, 89%), and improved awareness (17/18, 94%) regarding stroke telehealth. A comparison of matched pre- and posttraining responses revealed that training improved the understanding of telehealth workflow practices (after training: mean 4.2, SD 0.6; before training: mean 3.2, SD 0.9; $P<.001$), knowledge on accessing stroke telehealth (mean 4.1, SD 0.6 vs mean 3.1, SD 1.0; $P=.001$), the awareness of stroke telehealth (mean 4.1, SD 0.6 vs mean 3.4, SD 0.9; $P=.03$), ability to optimally communicate with colleagues (mean 4.2, SD 0.6 vs mean 3.7, SD 0.9; $P=.02$), and ability to make improvements (mean 4.0, SD 0.6 vs mean 3.5, SD 0.9; $P=.03$). Remote training and deployment were feasible, and limited issues were identified, although uptake varied widely (0-66 sessions/site).

Conclusions: TACTICS VR Stroke Telehealth is a new VR application specifically tailored for stroke telehealth workflow training at spoke hospitals. Training was considered acceptable, usable, and useful and had positive perceived training impacts in a real-world clinical implementation context. Additional work is required to optimize training uptake and integrate training into existing education pathways.

Introduction

Background and Rationale

Ischemic stroke is a leading (and increasing) cause of adult-acquired disability worldwide [1]. Longer time to reperfusion treatment has severe and negative impacts for patients with ischemic stroke [2], with a progressively increased likelihood of poor patient outcome with every hour of delay before reperfusion treatment is started [3]. Variability in clinical care is a major contributor to delayed treatment [4], particularly in rural areas, and there are numerous challenges in delivering best practice stroke management in rural contexts in Australia [5] and worldwide [6]. One significant contributor to delays at rural sites is the nature of the workforce, which is typically more junior, nonspecialist, and transient than the workforce at metropolitan hospitals, as well as having less access to continuing professional development training [7-9]. There is extensive clinical trial evidence to inform best practice stroke workflow to deliver reperfusion therapies (eg, thrombolysis and endovascular thrombectomy). However, additional research is needed to inform the implementation of effective workflow processes and training in real-world clinical settings, particularly in rural areas.

To address variability in stroke care in rural settings, telestroke networks have been developed in Australia [10,11] and worldwide [12,13], where rural spoke hospitals are supported by comprehensive centers. Locally, in New South Wales (NSW) in Australia, we first initiated a telestroke network in 2013 with a single rural hospital, which expanded over subsequent years to include 5 rural sites linked to a single comprehensive stroke center. The telestroke service aims to provide urgent access to a stroke neurologist, improving access to reperfusion therapies as well as outcomes at rural sites. To date, the service has documented increased thrombolysis treatment rates [14] and highlighted the value of multimodal computed tomography (CT) imaging for stroke diagnosis in rural areas [15]. The successful initial implementation of the local telestroke service provided pilot data [14] and is a cornerstone of the current statewide NSW Telestroke Service, which has undertaken a progressive rollout providing services to 23 rural hospitals [16,17]. The implementation of the statewide service started in March 2020, with staggered rollout across the 23 sites through June 2022. We proposed that virtual reality (VR) training to support telestroke service implementation would be useful at both existing and new sites as a complement to support existing training, new staff inductions, training refreshers for existing staff, and initial site onboarding.

Acute stroke management workflow is complex, and efficient team coordination and the sequencing of processes are challenging. The effective delivery of timely reperfusion treatment in acute ischemic stroke requires structured stroke workflow processes. Intensive quality improvement processes aimed at optimizing stroke workflow pathways by enhancing team communication and implementing site-specific processes can markedly improve reperfusion treatment delivery times [18-20], for example, the implementation of multifaceted implementation strategies via targeted quality improvement at 2 Australian comprehensive hospitals effectively reduced time to treatment [18,19]. However, site-specific stroke workflow pathways are often not applied at rural hospitals where there are gaps in local training and resourcing, transient workforces, and limited effective application of quality improvement activities. In this context, stroke telehealth services can complement local processes by providing access to expert neurologist support and implementing a structured routine for stroke workflow. Importantly, the successful integration of telestroke services requires training local staff to increase awareness, confidence, and competence in telestroke processes.

Staff education and training are critical for the delivery of evidence-based stroke management, but this is limited in rural settings. Less than two-thirds of Australian physicians and nurses involved in stroke management report having received any interactive or competency-based training, including approximately 60% of nurses and 40% of physicians [21]. Stroke management staff in regional areas, at sites with fewer annual stroke admissions (<75/year), and at sites without a dedicated stroke unit were less likely to have opportunities for professional development (63%, 62%, and 64%, respectively) [22]. Stroke workflow training is typically delivered by neurology specialists via traditional face-to-face workshops. This training happens infrequently, has high logistical complexity and costs, and cannot be readily accessed by all staff at a given rural hospital. The delivery of training via this traditional model was further impaired during the COVID-19 pandemic, when travel between sites was restricted [23]. On the basis of our previous work developing and implementing VR-based workflow training for health care staff in hyperacute stroke management in rural settings [24], we proposed VR-based training specific for stroke telehealth to support the implementation of the NSW Telestroke Service.

In medical fields, VR-based training consistently increases student engagement and motivation [25,26] and is effective for practical skills acquisition [27,28] and knowledge development [29-31]. VR technology has previously been applied in the context of both stroke management and medical education [32-34]. To date, VR applications for stroke have primarily targeted patients rather than health care professionals (eg, in the context of limb rehabilitation [35,36]). In the broader medical education context beyond stroke, most VR training applications for health care professionals have only been assessed in small pilot trials or in the context of medical school or residency training (systematic reviews and meta-analyses [37-39]).

In a nontelehealth context, we previously developed and implemented a novel fit-for-purpose VR-based stroke workflow training application called TACTICS VR Hyperacute Stroke Management [24]. During initial implementation in the first trial cluster of 7 hospitals, TACTICS VR users reported a high degree of usability, acceptability, utility, and feasibility [24]. Trainees self-reported increased confidence in their ability to make improvements in stroke management after training [24]. The application is currently actively being assessed in the Trial of Advanced CT Imaging and Combined Education Support for Drip and Ship, which is implementing a *package intervention* to support advanced CT imaging and streamlined workflow training at rural sites in 3 Australian states and will also report effects on clinical behavior and patient outcomes [40]. On the basis of the initial success of implementing TACTICS VR training in rural hospitals within a clinical trial context, we proposed the development of a second TACTICS VR module to support the implementation of the NSW Telestroke Service in this study.

Study Objectives

This paper describes the development and implementation of TACTICS VR Stroke Telehealth, a VR training module for spoke hospital workflow processes. The platform was conceptualized to support the NSW Telestroke Service rollout and provide improved training and awareness on effective stroke management to health care professionals at spoke hospitals involved in stroke management (eg, physicians, nurses, and radiographers). The study aims to assess TACTICS VR Stroke Telehealth implementation against critical elements that typically predict the future adoption and uptake of new technologies in educational practice. This includes the feasibility of the platform as a training resource in a real-world clinical setting, specifically in rural areas. Furthermore, end user acceptance, including perceived usefulness and usability, and perceived training impacts are assessed via survey feedback.

Methods

Ethical Considerations

Ethics approval for the overall NSW Telestroke Service research protocol was granted by the Prince of Wales Hospital Human Research Ethics Committee. Because of the practical constraints of ethics approval being governed at a local health district level, the collection of user survey feedback was limited to a subset of sites within a single local health district (n=7) via ethics approval from the Hunter New England Human Research Ethics Committee (REGIS Ref 2019/ETH01238 and HNEHREC Ref 18/09/19/4.13) lodged with The University of Newcastle Human Research Ethics Committee (H-2019-0343). Before the deployment of TACTICS VR training, all study sites provided consent to participate. Individual user participation was voluntary, and users were able to use TACTICS VR without participating in the study. Participants were advised that their consent was implied by the completion of the surveys.

Project Conception and Scoping

The NSW Telestroke Service was jointly funded by the NSW and Australian federal governments in 2019, with service delivery at the first rural sites starting in March 2020 [16,17]. It is a collaboration between the Prince of Wales Hospital, eHealth NSW, the NSW Agency for Clinical Innovation (ACI), and the NSW Ministry of Health in partnership with the Australian Stroke Foundation. The NSW Telestroke Service was rolled out progressively to its total coverage, with the final sites activated in June 2022, providing services to 23 rural hospitals across NSW [41].

TACTICS VR Stroke Telehealth was initially conceived through discussions among the Centre for Advanced Training Systems (ATS) at The University of Newcastle, the ACI, and the NSW Telestroke Service in 2019, informed by the development and implementation of the first TACTICS VR Hyperacute Stroke Management module within the TACTICS trial [24,40].

Study Methodology and Protocol

Overview

A descriptive survey study approach was applied to the creation and deployment of TACTICS VR Stroke Telehealth. Quantitative and qualitative data were collected during the development (from May 1, 2020, through April 14, 2021) and implementation of the training module across 23 hospitals in NSW (from April 14, 2021, through August 20, 2023). A particular focus was placed on assessing elements that typically predict technology adoption, including end user acceptance (perceived usability and usefulness), training impacts, and the practical challenges of technology delivery within a real-world health care setting.

TACTICS VR Stroke Telehealth Module

TACTICS VR Stroke Telehealth was developed for the stand-alone Oculus Quest 2 enterprise-enabled headset (Oculus or Meta) using the Unity platform (Unity Technologies). A detailed overview of included scenes, key features, objectives, and user interactions is provided in Table 1, with representative images presented in Figure 1. Users initially enter a 3D VR infinity space containing the application menu and brief overview text about the application. Upon initiating training, users are requested to provide brief demographic information (eg, hospital location and position title) and are provided a video overview of the training module and instructions on how to use the VR technology. Users then proceed through a single real-world stroke case from the prenotification and initial assessment phase through multimodal CT imaging, consenting, treatment with thrombolysis, and patient transfer for endovascular thrombectomy. Specific emphasis is placed on 3 telehealth consults for assessment, imaging interpretation, and consenting and treatment, with all other aspects of the workflow streamlined to minimize the total length of training. Users interact with elements in the VR environment, including avatars (eg, patient and nurse), equipment (eg, telephone and computer), and question and answer prompts to gather case information and prompt active decision-making. Suboptimal decisions result in immediate feedback (via text or audio) and time penalties, providing an element of gamification. For each user interaction, the accuracy was calculated as the number of suboptimal decisions selected (including both suboptimal decisions made and optimal decisions missed) as a percentage of total possible decisions. Time penalties for each suboptimal decision (or missed optimal decision) were arbitrarily determined through context expert feedback based on the perceived priority and impact that the specific decision would have on real-world workflow times (ie, suboptimal decisions deemed more serious were assigned larger time penalties). A stroke clock and an estimate of neuron loss are displayed at the top of the screen to emphasize the importance of accurate and timely workflow and model the real-world consequences of delayed or inaccurate decision-making. At the end of the module, users are provided with feedback on their training, including time spent in training, errors, and time penalties.

TACTICS VR Stroke Telehealth was integrated into the existing TACTICS VR training platform, which includes a public-facing supporting website [42] and backend automated database and password-protected reporting environment (Figure 2). A detailed overview of the TACTICS VR training platform has been published previously [24]. In this study, the public website was updated with a streamlined design to include information about the VR training module, the development process, funding sources, and contributors and stakeholders [42]. The database and reporting environment were duplicated from the first TACTICS VR module and updated to reflect locations, user interactions, and scenes from the TACTICS VR Stroke Telehealth module to support the automated tracking of training implementation. The developed training module was endorsed by the Australasian Stroke Academy.

Table 1. TACTICS VR Stroke Telehealth scenes, key features, objectives, and user interactions.

Scene	Features	Objectives	User interactions
Start and introduction	• VR[a] infinity space • Contributor and funding information • Demographics capture (location, position title, department, experience, and previous TACTICS VR use)	• Initiation of training • Demographics capture • Overview of training application (objectives and functionality)	• Navigation buttons • Q&A[b]: demographics • Talking head video
Prehospital notification and initial assessment	• VR ED[c] environment • Patient assessment (case details, symptoms, previous function, and history)	• Familiarization with stroke assessment processes and resources • Clarification of critical data required	• Avatars: patient, next of kin, paramedic, and nurse • Q&A: workflow processes and team interactions
Telehealth consult 1: initial assessment	• Telephone consultation • Communication of critical data • Coordination of local team and imaging staff • Patient transfer to imaging department	• Familiarization with telestroke processes • Workflow decision-making and team coordination	• Telephone interaction: telestroke neurologist
Radiology and imaging	• Virtual radiology suite with CT[d] machine	• Clear communication to initiate imaging • Timing of telehealth follow-up	• Avatars: patient and radiographer
Telehealth consult 2: imaging	• Virtual web conferencing communication • Patient transfer to ED or resuscitation suite	• Interpretation of imaging • Treatment decision-making	• Audiovisual: imaging with neurologist commentary • Q&A: workflow processes, treatment decision, and team coordination
Telehealth consult 3: consent and treatment	• Virtual ED or resuscitation suite with workstation on wheels	• Familiarization with consenting process • Treatment administration • Considerations for patient EVT[e] transfer	• Avatars: patient, next of kin, and nurse
Feedback	• User performance (time, errors, and penalties)	• User receives feedback on performance • User provides feedback on training utility	• User feedback on training (based on a scale ranging from 1 star to 5 stars)

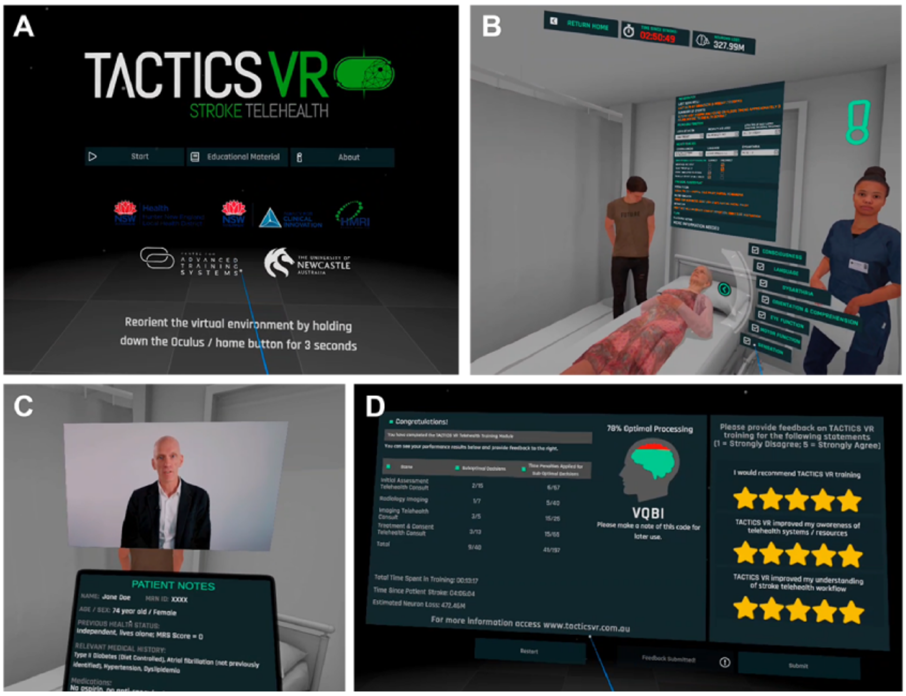

Figure 2. TACTICS VR training platform. The preexisting TACTICS VR platform was updated to integrate (A) a publicly accessible website for user support and educational resources as well as (B) an automated backend analytics portal for the collection of training uptake and user performance data.

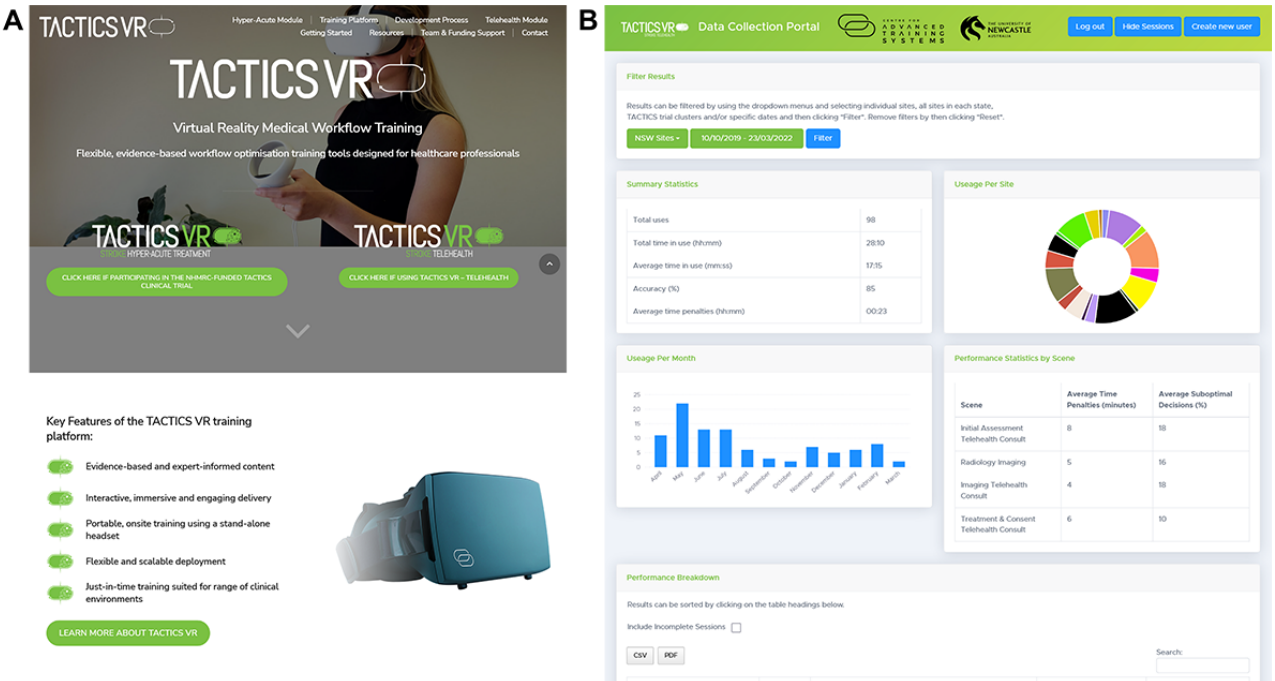


Study Participants and Recruitment

Stroke coordinators at spoke hospitals were requested to encourage any relevant health care staff involved in stroke management at their site to use TACTICS VR Stroke Telehealth training. All health care staff who tested the application were invited to participate in the data collection regarding its utility and training impact. Health care professionals from any background (eg, physicians, nurses, and radiographers) involved in stroke care and as identified by the stroke telehealth coordinator, were encouraged to explore TACTICS VR and provide automated anonymous feedback within the headset. Additional structured pre-post survey data were collected from this population at 7 spoke sites, with corresponding ethics approvals.

Measures: Self-Report and Survey Data

Self-report data (qualitative and quantitative in nature) were collected both automatically within the headset for all users and via separate structured pre-post surveys deployed at specific locations, with corresponding ethics approvals.

Within the TACTICS VR Stroke Telehealth module, basic demographics information and user feedback (location, position title, relative stroke management experience, previous use of TACTICS VR, and user ratings) is automatically collected via user prompts within the headset and automatically transferred via Wi-Fi to the password-protected reporting environment. These data are presented as TACTICS VR *user data* throughout this manuscript.

Additional structured survey responses were collected from trainees at the 7 spoke sites before and after TACTICS VR Stroke Telehealth training. Surveys collected more detailed feedback on training usability, usefulness, and perceived training impact. All survey data are referred to as *TACTICS VR survey response data* provided by *respondents* throughout this manuscript.

The administered surveys were generated by the research team and adapted from previous studies to accommodate the limited availability and time constraints of health care staff. Informed by the technology acceptance model [43-45], the survey items and domains focused on perceived acceptability, usability, usefulness, and training impacts and included individual items from validated scales, where appropriate [46,47].

Items within the pretraining survey aimed to collect relevant demographic information (eg, specialty area, position title, previous stroke telehealth experience, and VR experience), general expectations of VR-based training, and anticipated learnings. Items within the posttraining survey aimed to collect feedback on TACTICS VR Stroke Telehealth training (eg, hardware comfort, design, user interactions, and areas of improvement), usability, and usefulness and perceived value. Items relating to stroke workflow awareness, knowledge, and skill confidence aligned with TACTICS VR learning objectives and were included in both pretraining and posttraining surveys to assess training impacts via pretraining survey versus posttraining survey statistical comparisons.

The full lists of questions and responses are provided in Tables S1 and S2 in Multimedia Appendix 1.

Data Analysis

Self-report data were summarized and presented as mean (SD) or absolute number of responses, using Prism (version 8.0; GraphPad), and every response was included.

Statistical analysis was performed using Prism (version 8.0). Comparisons between pre- and posttraining responses to matched questions were analyzed using paired Wilcoxon tests for nonparametric data. *P* values of <.05 were considered statistically significant for all analyses.

Because of the limited number of open-ended survey responses, no formal analysis of qualitative data was performed. Points that were repeatedly mentioned in the open-ended responses were identified by the study investigators, and examples are provided in the *Results* section (a full list of responses is provided in Table S2 in Multimedia Appendix 1).

Results

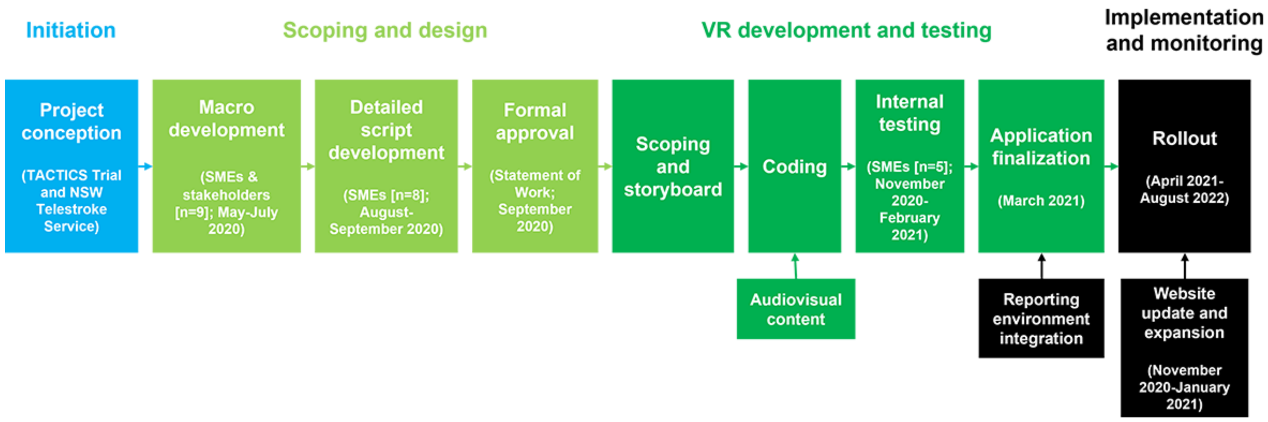
Development of TACTICS VR Stroke Telehealth

The overall concept and philosophy for TACTICS VR Stroke Telehealth built on the preexisting TACTICS VR module and training platform [24]. TACTICS VR Stroke Telehealth was developed using a structured stepwise approach throughout (an overview schematic is presented in Figure 3). Most importantly, the development involved and actively included subject matter experts (SMEs) and stakeholders. Specifically, members from the ATS, the ACI, and the NSW Telestroke Service as well as experts, including specialist neurologists, nurses, and radiographers, were consulted and were active creators of the platform from concept to software development.

An initial *macrolevel* overview of stroke telehealth workflow was generated based on NSW Telestroke Service workflow protocols, training resources, existing education materials, and informal SME interviews. This process identified key aspects of workflow procedures and provided contextual insights. A working group of SMEs was formed to review draft script documents and provide insights into common mistakes that delay telestroke workflow. All feedback was integrated into a single statement of work, which was reviewed by stakeholders via web conferencing. Subsequent meetings with SMEs informed the development of a detailed script document specifying specific user interactions, questions and answers, user feedback, and digital media content for inclusion (eg, reference images and talking head videos). The completed workflow was summarized into a single document and formally approved by SMEs as well as members of the ATS, the ACI, and the NSW Telestroke Service. The approved statement of work was circulated to content developers to inform quotes and development. This process was chosen to ensure the development of a fit-for-purpose training tool that would be accepted by trainees and experts in the field.

Software development proceeded stepwise through four key phases: (1) VR scoping and concept creation, (2) content development and refinement, (3) internal beta testing, and (4) application finalization.

Figure 3. TACTICS VR Stroke Telehealth development pathway. Development occurred via a structured process from initiation through scoping and design, content development, iterative rounds of internal testing, implementation, and monitoring. NSW: New South Wales; SME: subject matter expert; VR: virtual reality.



TACTICS VR Stroke Telehealth Implementation

TACTICS VR was deployed as part of the NSW Telestroke Service, which embeds stroke coordinators at telehealth spoke sites and includes structured education and training, communications (eg, communities of practice), the deployment of technology (eg, workstation on wheels and web conferencing), and ongoing support.

Headsets were shipped out to telestroke site coordinators at 23 participating locations. Using enterprise-enabled headsets allowed the remote monitoring of activations, battery status, and the update deployment of the software, removing the management burden from the telestroke coordinators and making it the responsibility of a dedicated centralized position. Telestroke site coordinators were initially briefed and trained with the VR headset on a site-by-site basis via web conferencing and provided supporting documents (eg, a quick-access guide and an instruction manual). Site coordinators were then requested to encourage any health care staff involved in stroke management at their spoke hospital to use TACTICS VR training (in particular, members of the stroke team as well as emergency department and radiology and imaging staff [eg, physicians, nurses, and radiographers]).

A total of 177 TACTICS VR sessions were logged at 20 (87%) of the 23 NSW Telestroke Service sites between April 14, 2021, and August 20, 2023. The number of completed training sessions per site ranged from 0 to 66 (mean 7.3, SD 13.1; median 4.5).

The mean time spent in VR training was 17 minutes 14 seconds per session, equating to a total of 50 hours 48 minutes across all sessions.

TACTICS VR User Data

TACTICS VR user data collected within the headset showed that those who used the platform primarily worked in acute stroke or neurology (94/177, 53.1%) and emergency care (63/177, 35.6%), followed by intensive care (7/177, 4%), radiology (4/177, 2.3%), stroke rehabilitation (2/177, 1.1%), and other (7/177, 4%). Users were employed as physicians (*in training*: 79/177, 44.6%; staff specialist: 25/177, 14.1%) or nurses (nurse: 50/177, 28.2%; nurse practitioner: 2/177, 1.1%), with the remainder being radiographers (4/177, 2.3%) or other (16/177, 9%). Of the 177 users, 33 (18.6%) had previously used a TACTICS VR training module. The users had a range of previous stroke management experience in terms of both total patient numbers and years, with a bimodal distribution of users reporting low or high experience (Table 2).

The mean user response accuracy was 87.2% (SD 8.3%) overall, resulting in an average of 22 (SD 19) minutes in time penalties per session. User accuracy was highest for each of the scenes relating to treatment and consent telehealth (91%), followed by each of the scenes for initial assessment telehealth consult (83%), radiology imaging (83%), and imaging telehealth consult (83%). Upon completing training, users provided positive in-headset feedback on TACTICS VR training by rating statements on a scale ranging from 1 star to 5 stars: “I would recommend TACTICS VR training” (n=127): mean 4.6, SD 0.8; “TACTICS VR improved my awareness of telehealth systems/resources” (n=126): mean 4.6, SD 0.7; and “TACTICS VR improved my understanding of stroke telehealth workflow” (n=126): mean 4.6, SD 0.7 (Table 2).

Table 2. TACTICS VR users have a diverse range of stroke experience and report positive training impacts of the TACTICS VR Stroke Telehealth module in the headset. For both stroke management queries, n=177; N values are included for the TACTICS VR feedback fields (n=126-127).

Stroke management experience	Response in VR[a] headset
Stroke management experience, n (%)	
<10 patients	90 (51)
11-20 patients	27 (15)
21-30 patients	12 (7)
31-40 patients	7 (4)
>40 patients	41 (23)
Stroke management experience, n (%)	
0 years	51 (29)
1-5 years	68 (38)
6-10 years	31 (18)
11-15 years	20 (11)
16-25 years	5 (3)
>25 years	2 (1)
TACTICS VR feedback[b], mean (SD)	
TACTICS VR improved my understanding of stroke telehealth workflow (n=126)	4.6 (0.7)
TACTICS VR improved my awareness of telehealth systems and resources (n=126)	4.6 (0.7)
I would recommend TACTICS VR training (n=127)	4.6 (0.8)

[a]VR: virtual reality.

[b]Responses collected in VR headset on a scale from 1-5 stars.

TACTICS VR Survey Response Data

A total of 21 pretraining and 20 posttraining survey responses were received from 4 sites (from a total of 26 VR sessions across the 7 survey-eligible sites; completed between May 2021 and September 2022; 21/26, 81% response rate during the survey deployment time frame). Survey respondents primarily worked in emergency care (14/21, 67%); there was also representation from acute stroke and neurology (3/21, 14%), intensive care (1/21, 5%), and other (stroke dietitian, research, and general or acute medicine: 3/21, 14%). Of the 21 respondents, 10 (48%) were employed as nurses, 10 (48%) as physicians, and 1 (5%) as a stroke dietitian; in addition, 3 (14%) were currently involved in a training program. Respondents had a range of previous experience in both stroke management and telestroke (Table 3). Of the 21 respondents, 2 (10%) indicated that they were prone to motion sickness when asked a binary yes or no question (17/21, 81% answered *no*).

Respondents had minimal previous experience with VR technology in any context (Table 3), and 3 (14%) of the 21 respondents had previously used any TACTICS VR training module. Before completing training, respondents indicated that they were likely to use telehealth in the future (19/21, 90% answered: mean 4.2, SD 1.0; 1=strongly disagree and 5=strongly agree) and were somewhat confident in their ability to effectively assess and treat patients with stroke (21/21, 100% answered: mean 3.5, SD 0.9; Table 3). Before the training, respondents were somewhat confident in managing the technical aspects of VR training (21/21, 100%: mean 3.6, SD 0.8; Table 3) and considered VR an effective method to teach or transfer knowledge about stroke telehealth workflow (21/21, 100% answered: mean 3.8, SD 0.8; Table 3).

After completing TACTICS VR Stroke Telehealth training, respondents provided positive feedback on the hardware, user interface, and training content across a range of aspects, including comfort, enjoyment, utility, accuracy, effectiveness in transferring knowledge, realism, and the quality of feedback (mean scores ranged from 3.8 to 4.4; 1=strongly disagree and 5=strongly agree; Table 4). Furthermore, respondents agreed that TACTICS VR Stroke Telehealth training increased their confidence in stroke telehealth (18/20, 90% answered: mean 3.8, SD 0.8; 13/18, 72%: agree or strongly agree), improved their understanding of stroke telehealth (18/20, 90% answered: mean 4.2, SD 0.8; 16/18, 89%: agree or strongly agree), improved their awareness of stroke telehealth (18/20, 90% answered: mean 4.3, SD 0.6; 17/18, 94%: agree or strongly agree), and indicated that as a result of TACTICS VR Stroke Telehealth training, they were more likely to use stroke telehealth in the future (19/20, 95% answered: mean 4.0, SD 0.8; 14/19, 74%: agree or strongly agree; Table 4).

A comparison of responses to matched questions between pre- and posttraining surveys indicated that TACTICS VR training increased user confidence in the understanding of telehealth workflow processes (after training: mean 4.2, SD 0.6; before training: mean 3.2, SD 0.9; median 4, IQR 4-5 vs median 4, IQR 3-4; $P<.001$), knowledge around accessing stroke telehealth (mean 4.1, SD 0.6 vs mean 3.1, SD 1.0; median 4, IQR 4.00-4.25

vs median 3, IQR 2-4; *P*=.001), awareness of local stroke telehealth services or processes (mean 4.1, SD 0.6 vs mean 3.4, SD 0.9; median 4, IQR 4.00-4.25 vs median 4, IQR 2.50-4.00; *P*=.03), ability to optimally communicate with colleagues to enable effective treatment (mean 4.2, SD 0.6 vs mean 3.7, SD 0.9; median 4, IQR 4-5 vs median 4, IQR 3-4; *P*=.02), and ability to make improvements to how stroke care is provided (mean 4.0, SD 0.6 vs mean 3.5, SD 0.9; median 4, IQR 4-4 vs median 4, IQR 3-4; *P*=.03; Table 5). A nonsignificant trend was also noted toward increased confidence in the understanding of general workflow practices to manage patients with acute stroke (mean 4.3, SD 0.5 vs mean 3.9, SD 0.6; median 4, IQR 4-5 vs median 4, IQR 4-4; *P*=.15), noting that self-reported pretraining confidence was already relatively high. Of the 20 respondents, 3 (15%) reported that they experienced motion sickness, but all were able to complete training. None of the respondents reported technical issues using TACTICS VR Stroke Telehealth, and the majority (13/18, 72%) believed that additional TACTICS VR training modules should be developed.

When asked an open-ended question on which elements of the TACTICS VR Stroke Telehealth training module were most beneficial, respondents primarily noted the VR virtual environment, interactions or interactivity, content presentation, and the overview of the complete workflow process. Selected comments are provided herein (all responses are available in Table S2 in Multimedia Appendix 1):

- Visual environment and scans, feedback on selections made, and step-by-step process
- Explanation of telestroke workflow and input
- Easy to follow
- Instant feedback: “awesome”
- Explanations provided at each decision point
- Feedback or interaction

Respondents were also asked which elements of TACTICS VR Stroke Telehealth could be improved, and they primarily identified aspects relating to VR technology familiarity, site-specific differences in processes, and areas for future development or expansion (eg, role-specific workflow modules). Comments included the following:

- Mock scenario at beginning or instructions on how to navigate through scenarios
- Perhaps the selections could be more clear regarding only selecting the first step in parallel (ie, “checklist that you tick”)
- Role oriented (not nurse specific; “seems more medical officer”)
- Further information regarding interpreting scans, including information regarding contraindications to tissue plasminogen activator or endovascular clot retrieval (stroke treatments)

Respondents who indicated that the additional TACTICS VR training modules should be developed (13/18, 72%) were asked what additional modules would be useful. Responses included the following:

- Allied health team involvement (or physiotherapist, speech therapist, and dietitian to demonstrate the whole of team care)
- Trauma survey and cardiac thrombolysis
- Procedural skills training

Table 3. Pretraining survey respondents have a range of stroke management experience, limited virtual reality (VR) experience, and existing attitudes to VR training.

Stroke, telestroke, and virtual reality experience	Survey response
Approximately how many acute stroke patients have you cared for or treated over the course of your career? n (%)	
Less than 10 patients	7 (33)
11-20 patients	4 (19)
21-30 patients	2 (10)
31-40 patients	2 (10)
41 patients or more	6 (29)
Approximately how many stroke telehealth cases have you been involved in? n (%)	
0 patients	8 (38)
1-4 patients	8 (38)
5-9 patients	0 (0)
10-14 patients	2 (10)
≥15 patients	2 (10)
Not applicable to my practice	1 (5)
What is your experience with virtual reality technology? n (%)	
Over 100 hours of usage	0 (0)
50-99 hours of usage	0 (0)
10-49 hours of usage	1 (5)
Less than 10 hours of usage	6 (29)
No experience	14 (67)
Pretraining confidence and attitudes[a], mean (SD)	
I am likely to use telehealth services in the future	4.2 (1.0)
I am confident in my ability to effectively assess or treat acute stroke patients	3.5 (0.9)
I feel confident in regards to managing the technical aspect of the VR training tool	3.6 (0.8)
I believe that VR can be an effective method to teach or transfer knowledge about stroke telehealth workflow	3.8 (0.8)

[a]Pretraining survey responses collected on 5-point Likert scale (1=strongly disagree and 5=strongly agree; n=19-21).

Table 4. Survey respondents provided positive feedback on TACTICS VR Stroke Telehealth training and reported perceived training benefits.

	Posttraining survey response[a], mean (SD)
Feedback on TACTICS VR stroke telehealth	
The VR hardware (eg, headset and controller) were comfortable and easy to use	4.1 (0.9)
The TACTICS VR Telehealth user interface was straight-forward and easy to use (eg, menu system, buttons, etc)	4.4 (0.7)
I enjoyed TACTICS VR Telehealth training	4.2 (0.6)
TACTICS VR Telehealth provided useful information to be useful for trainees and staff in the management of acute stroke	4.2 (0.4)
TACTICS VR Telehealth provided accurate information	4.2 (0.7)
TACTICS VR Telehealth was an effective tool for transferring knowledge about stroke telehealth practices	4.4 (0.5)
The simulation was of sufficient realism to communicate the critical aspects of workflow	3.9 (1.0)
The feedback provided at the end of the VR training module was constructive and useful	4.0 (0.6)
Perceived training impact	
TACTICS VR Telehealth improved my awareness of stroke telehealth approaches	4.3 (0.6)
TACTICS VR Telehealth improved my understanding of stroke telehealth approaches	4.2 (0.8)
TACTICS VR Telehealth increased my confidence in stroke telehealth workflow	3.8 (0.8)
As a result of TACTICS VR Telehealth training I am more likely to use stroke telehealth services in the future	4.0 (0.8)

[a]Survey responses collected on 5-point Likert scale (1=strongly disagree and 5=strongly agree; n=17-20).

Table 5. Survey respondents provide positive feedback on perceived training effects regarding confidence, via comparison of posttraining versus pretraining survey responses.

Self-reported stroke management confidence	Pretraining survey response[a], mean (SD)	Posttraining survey response[a], mean (SD)	*P* value
I am confident in my understanding of telehealth workflow processes	3.2 (0.9)	4.2 (0.6)	<.001
I am confident in my knowledge around accessing telehealth for acute stroke assessment or treatment	3.1 (1.0)	4.1 (0.6)	.001
I am aware of local stroke telehealth services and processes	3.4 (0.9)	4.1 (0.6)	.03
I am confident in my ability to optimally communicate with my colleagues to enable effective treatment of acute stroke patients	3.7 (0.9)	4.2 (0.6)	.02
I am confident in my ability to make improvements to how acute stroke care is provided to patients presenting to this hospital	3.5 (0.9)	4.0 (0.6)	.03
I am confident in my understanding of workflow practices to manage acute stroke patients	3.9 (0.6)	4.3 (0.5)	.15

[a]Survey responses collected on 5-point Likert scale (1=strongly disagree and 5=strongly agree; n=17-21).

Discussion

Principal Findings

This paper describes the development and pilot implementation of TACTICS VR Stroke Telehealth, a VR-based training application specifically tailored for stroke telehealth workflow training. The TACTICS VR module was developed to address an identified training gap to support the rollout of the NSW Telestroke Service by, and with, involved stakeholders. In this study, we evaluated the acceptability, usability, and perceived training impacts of TACTICS VR Stroke Telehealth training across 20 rural NSW hospitals, including survey response data from a subset of 7 sites within a single local health district. The feedback indicated a high level of end user acceptability (including perceived usability and usefulness) among health care professionals involved in stroke management at telehealth spoke hospitals. Furthermore, the feasibility of deploying VR training in a real-world clinical setting outside of a formal clinical trial context was demonstrated, while noting that additional work is required to optimize training uptake and integration into existing training processes. TACTICS VR users provided positive feedback on application delivery and design. Survey respondents reported perceived improvements in key aspects of stroke telehealth management, including an increased understanding and awareness of telehealth workflow, knowledge around accessing stroke telehealth, an improved ability to optimally communicate with colleagues, and an increased ability to make improvements to stroke care.

Extensive participant feedback was very positive, and implementation was overall deemed feasible, but we believe that there is room for improvement in terms of overall training uptake. To encourage use and simplify deployment, we specifically developed training sessions that were relatively short (<20 minutes), included brief talking head videos emphasizing key learning objectives, and provided supporting documentation as well as a user-facing website so that training could be deployed on site without trainer support.

Although this study was not structured to objectively determine factors influencing site-specific implementation, the captured data and discussions did provide some useful insights to assess in future implementation interventions. Rural telestroke hospitals varied widely across a range of factors, including overall hospital size (from 30 to 520 beds), stroke team composition (eg, specific stroke teams vs emergency department–based or locum management, staffing numbers and positions, skill sets, and on-site vs off-site radiographers), resourcing and NSW Telestroke Service site coordinator demographics (eg, on site vs off site, preexisting members of the local team vs new appointments, clinical vs administrative background, and single site vs multisite coverage). Discussions with study investigators and site coordinators highlighted barriers relating to staffing (both trainer and trainee availability), existing attitudes and training frameworks, and competing priorities. Mapping these factors onto the theoretical domains framework highlights relevant aspects within the domains of knowledge, skills, social or professional role and identity, beliefs about capabilities, reinforcement, environmental context and resources, and social influences [48]. By applying the Behavior Change Wheel [49], we propose a range of strategies that could address these domains within local contexts, including education (eg, promoting awareness of, and practical skills in delivering, VR training; and tailored training documentation), persuasion (eg, making VR training a mandatory component of local staff orientation), incentivization, environmental restructuring (eg, local staffing and resourcing), enablement (eg, upskilling training facilitators and providing for dedicated training time), communication or marketing, and service provision (eg, facilitated training by an external service provider). In the long term, if VR training is demonstrated to be effective and sustainable in supporting clinical behavior change and improving patient outcomes, it may be appropriate to consider its integration into consensus guidelines and clinical pathways.

Future studies should seek to document enablers and barriers to VR training uptake and explore additional implementation approaches. To this end, we are currently assessing the effects of a range of approaches to TACTICS VR training uptake and sustainment, including making training mandatory, integrating training into existing continuing professional development credit systems, deploying VR headsets via roaming educators who travel among sites, providing time-limited access to hardware at individual sites on a rolling basis, delivering supported face-to-face education sessions or workshops where multiple staff members complete training in parallel (eg, 10 trainees/1-hour session), and embedding VR training within a broader staff training program with expert-supported debriefing. We anticipate that a combination of different implementation approaches and strategies, which applies a codevelopment approach to optimize training within each organization, will be useful to increase adoption across a range of rural sites with different needs.

As part of the development process, we also documented associated costs, which may be relevant to readers who are considering developing and implementing similar VR training in their specific context. Note that during the study period conversion rates ranged from approximately Aus $1 (US $0.6-$0.8). Direct costs associated with the development of TACTICS VR Stroke Telehealth training included VR application coding and updating of the existing automated analytics portal (approximately Aus $37,000; ie, ~US $24,200), expansion and redesign of the user-facing website (approximately Aus $4000; ie, ~US $2600), and hardware (VR headsets and Wi-Fi routers; approximately Aus $1800 [~US $1200] per site). Additional costs associated with project management, internal application testing, research assessment, ongoing support and maintenance, and implementation within the broader NSW Telestroke Service rollout were not specifically captured or reported.

Comparison With Prior Work

Telestroke services improve the rates of reperfusion treatment and functional patient outcomes without increasing the rates of treatment-induced hemorrhage, although it has been noted that evidence for impacts on resource use and cost-effectiveness is limited [50,51]. As a result, patients treated through telestroke networks achieve outcomes that are similar to those managed at comprehensive stroke centers [10,12,13]. Of note, in Australia, the importance of telehealth-supported stroke care was recently recognized through its inclusion in the Australia Stroke Foundation guidelines as best practice to improve outcomes in rural settings [52]. However, the effectiveness of stroke telehealth delivery depends upon a number of factors, including trained staff, infrastructure to support CT image transfer, videoconferencing capabilities, established protocols and processes, and funding. Furthermore, effective deployment requires the coordinated training of health care staff in telestroke workflows across diverse clinical settings. TACTICS VR Stroke Telehealth was developed to address this need.

VR technology is increasingly used to support training in a range of workplace settings, including health care. VR has advantages over traditional 2D training delivery approaches in terms of presence, privacy, and immersion [53], but the relative benefit of VR regarding training outcomes depends upon the specific application as well as the delivery context. Several recent systematic reviews have collated findings on mixed reality or VR and health care staff training, with specific focuses on head-mounted devices (HMDs) [37] or augmented reality in medical education [39] and VR-based training in nursing [38]. The majority of reported studies demonstrated the effectiveness of training (or noninferiority to traditional approaches), with greater trainee enthusiasm and enjoyment when using HMD-based technology in medical education [37]; improved performance time, confidence, and satisfaction using

AR for medical education [39]; and improved knowledge development using VR for nursing education [38]. However, the existing literature remains limited, with a low number of total studies (11-27 studies each across 3 systematic reviews), low total participant numbers (a total of 654-956 participants across all studies), and application to training in a limited range of medical fields (eg, 48% of HMD-based training studies in surgery and 15% in anatomy [37]). Notably, there has been limited application of VR technology for the continuing education of health care professionals, the target population in this study; for example, across all studies of HMD-based training in medical education, 60% of the study participants were medical students, and 30% were medical residents (ie, 90% combined) [37]. On the basis of the reported 956 total participants across all 27 studies, this indicates that only approximately 95 (approximately 10%) nontrainee participants were included [37]. Thus, the 177 VR sessions included in this study represent almost twice the total number of reported HMD-based VR training participants in the existing literature within a continuing medical education context. Across the 3 systematic reviews, the authors noted many limitations, including most of the studies being small-scale short-term pilot studies, often conducted in a single nonclinical setting with limited participant diversity in medical field or training stage and often poor-quality study design. Our study addressed several of these areas and provides insights into the application of VR training for the continuing education of health care professionals in a clinical context, which is a setting that is underrepresented—in terms of both population and training—in the existing literature. None of the studies identified in the systematic reviews specifically focused on the continuing education of health care professionals in stroke management. To our knowledge, the only VR applications that have been previously studied for stroke (other than our previous report of the first TACTICS VR module [24]) have targeted patient users to support poststroke rehabilitation (eg, limb motor function recovery) [35,36].

This study builds on our previous experience of developing the first TACTICS VR training module, which provided hyperacute stroke workflow training without telehealth integration [24]. The first TACTICS VR Hyperacute Stroke Management module continues to be assessed in a clustered stepped-wedge clinical trial across 3 Australian states, with data collection conducted through the end of 2022 [40]. This study differs from the previous work by upgrading content into a 6-degrees-of-freedom VR headset, developing training content specifically for stroke telehealth workflow, and assessing implementation outside of a formal structured clinical trial context. The specific elements incorporated into training include 3 telehealth consultation calls, a detailed voice-over walkthrough of CT imaging interpretation, the incorporation of an assessment support tool (termed the Acute Stroke Assessment Protocol Triage Tool), and a simulated workstation on wheels. Despite more limited infrastructure and support during implementation in this study, we noted very similar participant feedback on acceptability, feasibility, and utility, which was very encouraging. This study also builds on our previous work deploying VR training in workplaces outside of health care, which has highlighted the importance of considering broad institutional factors and developing frameworks that support training implementation, uptake, and ongoing sustainment [54-57]. Consistently across sectors (ie, in health, tertiary education [55,56], and defense [54]), these aspects must be considered and addressed at the organizational level to optimize training implementation and maximize effects.

Training programs for health care professionals in stroke management are typically delivered face-to-face by an experienced trainer or clinical expert with relevant expertise via traditional teaching modalities (eg, printed materials and slide-based presentations), informal mentor or mentee learning, and the passive distribution of guidelines and training materials. These approaches support the delivery of evidence-based clinically relevant educational content but are expensive to either deliver or scale across rural settings and are passive and limited in utility. Group education approaches contribute to relatively small improvements in professional practice (eg, <10%) [58] but are better than the passive delivery of clinical guidelines and recommendations. Limited studies have assessed simulation-based approaches to support stroke workflow training [59]. We propose that TACTICS VR training specifically and stand-alone VR-based training more broadly are a feasible and useful approach to supplement existing training modalities, particularly in rural contexts.

Limitations

We note several limitations, which should be considered when interpreting data from this study. First, study recruitment was led by on-site staff at spoke hospitals who were requested to target health care professionals involved in stroke management; as such, it was nonrandom. This was partially mitigated by encouraging site coordinators to recruit all staff involved in stroke management. Study participants primarily included physicians and nurses in emergency or acute stroke care. We note that the demographic mix captured from TACTICS VR users in the headset was similar to that of the survey respondents in terms of department, position title, and relative stroke experience. Although this was the intended target population for this training, their feedback on the utility of VR training to support workplace training more broadly may not be representative of all health care professional groups. It may be useful to specifically target additional training populations in future studies (eg, radiographers). Second, implementation was limited to hospitals in NSW, and detailed survey collection was limited to a subset of 7 sites, with corresponding ethics approvals. This was due to the complexities in obtaining specific ethics approvals for survey distribution across multiple local health districts and hospitals. Although it would be useful to collect additional data in specific local health districts or contexts to inform the location-specific integration of training in the future, we believe that the responses collected at the 4 sites are representative of the general feedback overall because the sites included are reflective of regional Australian spoke hospitals. Third, TACTICS VR Stroke Telehealth training was deployed as part of the NSW Telestroke Service, which included additional education materials, site visits, and follow-up support, as well as staffing and quality improvement activities. VR training was intended to complement these training approaches and resources as an add-on that can be deployed on site in rural settings. However, this approach does limit the ability to directly assess and attribute the effects of TACTICS VR training on clinical behavior or patient outcomes in isolation. Metrics on clinical behavior and patient outcomes are being captured as part of the NSW Telestroke Service implementation, which will provide insights into the effects of the overall program but will not allow an assessment of the direct effect of TACTICS VR Stroke Telehealth training specifically. Fourth, given the nature of this feasibility study, no control group was included; as such, we were unable to compare the effects of TACTICS VR Stroke Telehealth training with those of alternative approaches. Finally, the survey was intentionally kept short, noting the time constraints of study participants, and limited to study-specific questions. Additional assessments, including questions relating to the implementation approach as well as the application of validated instruments, may be useful in future studies (eg, assessing presence via the Presence Questionnaire [47], usability via the System Usability Scale [46], and engagement via the User Engagement Scale [60]).

Conclusions

User acceptance among those who used TACTICS VR Stroke Telehealth training was very high and included suggestions for future implementation and expansion. The feedback provided has directly led to the subsequent scoping and development of a dedicated stroke nursing module (TACTICS VR Stroke Nursing), and additional modules are in development to support paramedic-led stroke assessment and transport decision-making in a prehospital phase (TACTICS VR Stroke Paramedic). The platform is deemed feasible for deployment within a real-world clinical setting, supported by high ratings on perceived usability and usefulness. Further research is now required to document the effects of TACTICS VR training on clinical practice and patient outcomes as well as to assess cost-effectiveness. Further research will also be useful to optimize training uptake and identify approaches to support the integration of training into existing education pathways.

Acknowledgments

The authors thank Centre for Advanced Training Systems members, the New South Wales (NSW) Telestroke Service team, local site coordinators, and study participants for their valuable input and feedback, which made this project possible. Specific contributors are listed on the TACTICS VR website [42]. The authors thank Sally Ormond for support with survey collection, Martine Cox for ethics submission support, and Briony van Galen and Rimen Lim for VR content review. Furthermore, the authors thank Jumpgate VR staff (particularly Lewis McLauchlan) for their work and input coding TACTICS VR Stroke Telehealth and the development of the reporting environment portal as well as HyperWeb staff (particularly Brendan Brooks) for the development of the TACTICS VR website. The implementation of the NSW Telestroke Service was jointly funded by the NSW and Australian federal governments. The direct funding of the TACTICS VR Stroke Telehealth module was provided by the NSW Agency for Clinical Innovation as a partnership grant. Intellectual property for the TACTICS VR training platform is owned by The University of Newcastle (Newcastle, NSW, Australia). Those interested in accessing any TACTICS VR application for research purposes may contact the corresponding author. The funding agencies were not involved in the study design, collection, analysis, the interpretation of data, the writing of this manuscript, or the decision to submit it for publication.

Authors' Contributions

SM, CG-E, KJ, KB, JWE, WOB, MGK, AR, CLP, NJS, CRL, and FRW conceptualized the study. SM, MGK, and FRW conducted the formal analysis. SM, MGK, and FRW were responsible for funding acquisition. SM, CG-E, KJ, KB, CD, SR, NW, MGK, AR, NJS, CRL, and FRW conducted the investigation. SM, CG-E, KJ, MGK, AR, CLP, NJS, CRL, and FRW were responsible for the methodology. SM, CD, SR, NW, and FRW were responsible for project administration. KB, JWE, and WOB were responsible for resources. KB, NJS, CRL, and FRW supervised the study. SM, MGK, and FRW wrote the original draft, and all authors reviewed and edited the manuscript.

Conflicts of Interest

All authors were involved in the development of the TACTICS VR Stroke Telehealth application. KJ, CD, SR, and NW are employed by the New South Wales Agency for Clinical Innovation and work to support implementation of the New South Wales Telestroke Service, but they were not involved in funding decisions for this study.

Abstract

Background: Virtual reality (VR) adventure games can offer ideal technological solutions for training social skills in adolescents with autism spectrum disorder (ASD), leveraging their support for multisensory and multiplayer interactions over distance, which may lower barriers to training access and increase user motivation. However, the design of VR-based game environments for social skills training is still understudied and deserves the deployment of an inclusive design approach to ensure its acceptability by target users.

Objective: We aimed to present the inclusive design process that we had followed to develop the Zentastic VR adventure game to foster social skills training in adolescents with ASD and to investigate its feasibility as a training environment for adolescents.

Methods: The VR game supports multiplayer training sessions involving small groups of adolescents and their therapists, who act as facilitators. Adolescents with ASD and their therapists were involved in the design and in an explorative acceptability study of an initial prototype of the gaming environment, as well as in a later feasibility multisession evaluation of the VR game final release.

Results: The feasibility study demonstrated good acceptability of the VR game by adolescents and an enhancement of their social skills from baseline to posttraining.

Conclusions: The findings provide preliminary evidence of the benefits that VR-based games can bring to the training of adolescents with ASD and, potentially, other neurodevelopmental disorders.

Introduction

Background

Impairments in social skills represent a central feature of autism spectrum disorder (ASD), a neurodevelopmental disorder affecting verbal and nonverbal social communication in children [1]. Approximately 44% of children with ASD have IQ scores in the average and above-average range [2]. However, they may experience difficulties in social skills such as an absence of social reciprocity, a poor display of eye contact and facial expressions, a lack of nonverbal behaviors and gestures, and difficulty in acquiring and maintaining peer relationships. Individuals with ASD commonly have difficulties with exhibiting the appropriate social skills across contexts [3] and facing social tasks required by complex situations in community life, school, and work [4].

Different methods and interventions have been designed to facilitate the acquisition of social skills in adolescents with ASD, including video-based instruction, in vivo instruction, high-tech augmentative and alternative communication, low-tech augmentative and alternative communication, behavioral skills training, social skills training [5], and play-based interventions in virtual environments.

Virtual reality (VR) is a computer-generated 3D simulation of imaginary or real-life environments that is explored and interacted with by real-time users. VR can take variant forms, ranging from desktop computer rendering of a highly interactive virtual world to a fully immersive multisensory environment in laboratories [6]. VR has some intrinsic appeal as a training tool for children with ASD, who tend to learn using visual support [7,8]. A VR-based learning environment allows participants to practice social skills in a nonthreatening, synthetic, but realistic, motivating, controllable, and diversifiable environment during learning [9]. There is evidence that VR technologies can, and do, represent authentic and plausible scenarios and social encounters, thereby reflecting and supporting real-world conventions, understandings, and behaviors for a range of different user groups [10-13]. Supporting multisensory interactions for multiple users over distance is another salient feature of VR that makes social skills training accessible in diverse formal and informal learning settings [14].

Despite its promise, the VR-based learning environment is still understudied and warrants further development and testing. Early efforts on studying VR-based learning for individuals with ASD proceeded from embedding multimedia direct instruction in a virtual world [15] to emphasizing multiplayer simulation and scenario-based social role-play [7,16,17]. In a recent pretest-posttest study with 30 children with ASD [17], researchers examined the effects of desktop VR–based social cognition training that involved children in social role-play with 2 to 3 peer- and clinician-controlled, confederate avatars in daily life social scenarios. The study showed participants' improvements in measures of emotion recognition, social attribution, and executive function of analogical reasoning. Another explorative study [18] provided preliminary evidence on the positive effect of desktop VR–based play- and design-oriented social skills training for children with ASD. The study also indicated some main challenges in designing and implementing a comprehensive social skill intervention for learners with ASD, such as the need for a longer duration of practice and learning sessions for novel or demanding social tasks. Previous work has also observed that gamified therapeutic interventions may run the risk of having a reduced appeal for children, especially when marginal relevance is given to game design, neglecting children's interests and their experience with video games available in the market [19]. According to recent studies, such risk is particularly relevant because children with ASD tend to spend nearly twice the amount of time playing video games than typically developing children do [20]. In a recent study, the authors proposed an inclusive design model to guide the development of effective and enjoyable therapeutic games, stressing the need to integrate knowledge from different perspectives, typically those of clinical experts, designers, and children [19].

Objective

The purpose of this study was to present how we applied an inclusive co-design approach [21,22] to develop a VR adventure game named Zentastic, fostering social skills acquisition in adolescents with ASD.

Methods

Overview

We describe our work in eliciting requirements from therapists and adolescents and merging their contributions in an early prototype of the multiplayer game; preliminary testing of the game with adolescents was performed to uncover their acceptance of the game, feedback, and preferences with respect to the game scenarios and mechanics proposed. We also describe how we incorporated the results of this preliminary explorative phase into the final release of the VR game and how we further evaluated the feasibility of our intervention with 12 adolescents and their therapists over a period of 3 weeks. Finally, in the Discussion section, we report the promising results achieved in the study, suggesting VR-based gaming interventions as viable and motivating solutions for training social skills in adolescents with ASD.

Co-Design of the Zentastic VR Gaming Intervention

This section describes the inclusive co-design approach [19,21] applied to develop the Zentastic VR gaming intervention by leveraging on the ideas and suggestions of the designers, the neurodevelopmental psychologists, and the children with ASD.

The Game Design Context

The Zentastic VR adventure game was designed in the context of the European Project XR4A (extended reality–enabled social skills therapy for adolescents with autism and neurodevelopmental disorders), which aimed at experimenting the application of VR gaming technologies as potentially engaging and motivating environments for training of social skills in adolescents with ASD. The game was developed through a close collaboration with ASD experts at ODFLab (Observational, Diagnosis, and Education Lab, University of Trento), a specialized center for children and adolescents with

ASD and neurodevelopmental disorders (Cooperativa Albero Blu) in Italy.

The motivation for developing a VR game to engage and train social skills in adolescents with ASD started with the assumption that VR technology can be conceptualized as a mediator of social interaction [19]. It can be an instrument for scaffolding and facilitating interpersonal relationships between adolescents, their therapists, and their peers in a training and therapeutic context [23]. To achieve this, it is important to design game experiences that are sufficiently engaging and valuable, so that the adolescents would feel motivated to initiate social interaction and communication in the playing setting, as well as to generalize the social skills acquired in everyday settings.

Eliciting Requirements From Experts

Requirements from psychologists and therapists at the local autism center, Cooperativa Albero Blu, were aimed at defining the structure of the VR game, the objectives, and the roles of players. To define these aspects, 4 meetings involving both designers and experts were arranged during the initial stage of the design process [19,21]. Each meeting lasted for almost 2 hours and involved between 2 and 4 experts from the local autism center. The first meeting focused on (1) introducing the 2 teams, interaction, VR game designers and ASD experts, (2) explaining the project objectives, (3) presenting state-of-the-art and key examples of VR game solutions for adolescents with ASD, and (4) sharing ideas and previous experiences of the teams in co-design methodologies [19,21,22] to be deployed in the VR game design.

The following meetings were arranged as brainstorming sessions aimed at establishing the conditions for cocreation through a merging of design ideas and clinical requirements. For this purpose, after each meeting, the designer team produced a document summarizing the main ideas that emerged and the decisions taken and sketching some initial proposals for the game structure to be discussed in the following meeting.

During the subsequent phases of the VR game design and prototyping, additional meetings were organized to evaluate our progress. The analysis of the requirements collected from the ASD experts and the study of their current use of game-based approaches in the training of adolescents with ASD allowed us to properly frame the scope of the VR gaming intervention as well as our target user group.

As the main goal of the project was to support social skills training in adolescents with ASD as an important enhancement in their daily activity and future lives, the target users specified by experts were adolescents aged 13 to 18 years with level 1 ASD severity, according to the *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition [1]. Children with level 1 ASD are those with higher cognitive development who have more chances of having an autonomous life if adequately assisted through their childhood and adolescence [1]. Therefore, we concentrated our efforts on this target user group, which might be more suitable and motivated to engage with multiplayer VR games and train their social skills by interacting with peers and therapists. The inclusion criteria defined by our experts were (1) a minimum IQ level of 70, which refers to the ability to understand the environment and hence, understand the VR game challenges presented; and (2) a diagnosis of autism with an Autism Diagnostic Observation Schedule module 3 with a minimum severity level of 4 (ie, having a fluent verbal capacity).

The game intervention plan recommended by the experts was characterized by a progressive scaffolding and elicitation of social interaction in the VR game, which is aligned with current practices in traditional treatment. This plan ensured that adolescents first familiarized themselves with the play environment, were introduced to the colocated play goals and challenges by their therapist, and then they shared the play experience with their peers (in groups of 2-4 players per session) to meet the game objectives. The VR game should enable social skills training over multiple sessions; therefore, the experts also expressed the need for having the possibility of tuning the level of difficulty of the game challenges to better adapt them to the players' needs and familiarity with the VR game.

The initial game structure was derived from the experts' requirements, defined around the Zentastic adventure game story. In the game, players were asked to enroll on a space journey to the Zentastic planet. The game mission consisted of overcoming different challenges in the attempt to find and retrieve the precious Zennite material, which was needed by the scientists on Earth to repair the ozone layer and thus ensure the survival of Earth.

The players' interaction patterns recommended by experts were based on a cooperative and collaborative model for the game experience, leveraging synergies between different user abilities, shared goals, and complementarities of player actions [24].

The experts also defined a set of core behavioral skills required in the game to foster social interaction and social skills training in adolescents with ASD. The required social skills were (1) turn taking; (2) social interaction and cooperation; and (3) executive functions such as sustained attention, selective attention, and inhibition that strengthen social skills.

These requirements led to the design of a basic structure of game mechanics, as reported in Table 1, to be implemented in the first VR game prototype and tested with adolescents for subsequent refinement according to their preferences and feedback.

Table 1. Core behavioral skills and game mechanics that were defined by experts in the design phase.

Game session and objectives	Game mechanics
Introduction	
Sustained attention	The player has to pay attention to the instruction provided by the facilitator.
First mission (Coin Hunt)	
Selective attention and inhibition	The player has to discriminate between the target objects and nontarget objects and avoid picking up nontarget objects.
Cooperation	The player has to collaborate with other players to collect as many target objects as possible.
Second mission (Space Station)	
Social interaction	The player has to interact with an agent to obtain a target object.
Turn taking	The player has to respect his turn to obtain a target object.
Third mission (Planet Battle)	
Sustained attention and inhibition	The player has to discriminate between the target objects and nontarget objects.
Cooperation	The player has to collaborate with other players to obtain the target objects as fast as possible.

The Zentastic Multiplayer VR Adventure Game

The Zentastic adventure game is an immersive multiplayer VR game (developed in Unity and deployed on Meta Oculus technology) aimed at promoting social skills training in adolescents with ASD. The game is designed to be played by small groups of adolescents (2-4 players per session) in the presence of a therapist who acts as a facilitator in the virtual environment. The overall objective of the adventure game is to go through different missions of the Zentastic journey, facing and overcoming the challenges presented to achieve the final goal of collecting the Zennite material and taking it back to Earth to save the planet. At the start of the game session, players gathered in front of the fire in a common room, where they were introduced to the game plot and objectives. The players were then presented with the first mission called the Coin Hunt, where each player needed to collect a target number of coins (level of difficulty set by the facilitator) of a certain color hidden in a park to proceed with the following mission. The targeted behaviors related to social interaction trained by this mission are sustained attention, selective attention, and inhibition required to collect only the right coins during their hunt. In the Space Station mission, the players were asked to interact with a ticket-office agent (role played by the facilitator) to buy a ticket for the space shuttle that would take them to the Zentastic planet. Here, the targeted behavior trained is mainly turn taking, as the players would have to respect their turn while queuing to buy the ticket and initiate social interaction with the ticket agent to purchase the ticket. In the Planet Battle mission, the players had to climb a hill where the Zennite material was stored, and they were assigned colored laser guns to shoot colored stones falling down the hill that prevented them from reaching the Zennite. The targeted behaviors trained here are not only sustained attention, selective attention, and inhibition (to shoot the right stones) but also collaboration to reach the hill's top as fast as possible as a team. At the end of the game, the players gathered again in the common room for a debriefing, congratulating on the experience and closing the session.

Each mission in Zentastic was designed to address a targeted behavior related to social interaction, with increasing complexity levels. A description of each mission and complexity level, corresponding to the intervention plan previously described, is provided in Textbox 1.

Textbox 1. Brief description of the Zentastic game missions and their challenges.

First mission (Coin Hunt)

- In this mission, the player has to collect a target number of coins that are each assigned a color and hidden in a park. The target number is set by the facilitator (the level of difficulty can vary), and players have to achieve the target number of coins as a team. The team score increases or decreases according to each right or wrong coin collected. An additional bonus score is added if the players accomplish their individual targets within certain time thresholds. Players can help each other during the game to find the coins. As soon as the challenge is completed, multimedia effects appear, and a gold coin is assigned to each player as a reward in the gazebo.

Second mission (Space Station)

- Here, the players have to buy the ticket to get into the shuttle that will take them to the Zentastic planet. Players need to interact with a ticket agent (played by the facilitator) who may have different conversational attitudes (supportive vs unsupportive) toward the player (to vary the level of difficulty). When reaching the ticket counter room, each player has to respect their turn to talk with the ticket agent by waiting in a colored spot (previously assigned). A happy meter will increase every 3 s if players stay within their spot and decrease if they leave their spot and buzz around.

Third mission (Planet Battle)

- Here, players are on the Zentastic planet, climbing a hill to obtain the Zennite material. To reach the hill's top, each player has to shoot at the rocks of assigned color that are challenging their climbing. Shooting at the wrong rock means losing 1 life. When all lives are lost, the player has to restart climbing from the bottom of the slope. The facilitator can vary the level of difficulty either by assigning the number of lives available to each player or by varying the speed of the falling rocks. Once the players have completed the challenge, the Zennite pile explodes, and each player gets a piece of Zennite to bring back to Earth.

Uncovering Adolescents' Expectations and Preferences

An initial evaluation of an early prototype of the Zentastic VR adventure game was conducted with children and adolescents with ASD who visited the autism center to investigate the acceptability and level of engagement of the target users with the game intervention designed. This explorative phase of co-design [21,22] was focused on collecting adolescents' expectations and preferences regarding the game experience to feed this information into a refinement and finalization of our VR prototype. The methods used to collect the users' feedback are as follows:

- Field observations of the behaviors exhibited by the participants during the VR game sessions to identify possible usability issues
- Short, structured postsession interviews aimed at understanding the level of satisfaction with the game experience and suggestions for improvements (Multimedia Appendix 1)

Overall, 31 participants with ASD were involved in this explorative study. This is justified in the literature review of studies using innovative solutions for adolescents with ASD by the difficulty of obtaining large samples when the aim of the study is related to psychopathology [25,26]. Participants included 25 (81%) adolescent boys and 6 (19%) adolescent girls; their average age was 13.2 (SD 3.41) years, their average Autism Diagnostic Observation Schedule score was 6.3 (SD 1), and their mean IQ was 96.6 (SD 20). All 31 participants performed at least 1 session of the VR game; 27 (87%) participants performed 2 sessions; 19 (61%) participants were involved in 3 sessions; and 3 (10%) participants performed 4 sessions.

Most participants (25/31, 81%) had an overall positive experience with the VR gaming environment, as evidenced by the high average scores (scale 1-5: 1=not at all; 5=very much) in the level of engagement and enjoyment with the VR experience (Table 2).

Table 2. Participants' appreciation of the virtual reality (VR) gaming environment on a scale of 1 to 5 (1=not at all; 5=very much) in the explorative study.

Factor measured	Score, mean (SD)
Clarity of VR game	4.1 (0.8)
Engagement	4.1 (0.9)
Interaction with objects	4.3 (0.7)
Movement in VR	4.1 (0.9)
Object grasping	4.1 (0.9)
Interaction with the environment	4.2 (0.8)
Focus on activity	3.8 (0.9)
Enjoyment	4.5 (0.9)
Willingness to play again	4.6 (0.9)

Regarding the interaction with the VR hardware required for playing, some difficulties were observed, especially with the use of the controllers, and a few participants (4/31, 13%) experienced nausea after prolonged activity in VR (Table 3).

Regarding the emotional feelings of the participants after interacting with the VR gaming environment, 81% (25/31) of the participants reported feeling happy or relaxed, and 19% (6/31) reported feeling frustrated or confused.

From the postsession interviews with participants, some suggestions for improving the VR gaming experience were collected, which are as follows:

- Improving movement in VR: some participants pointed out that moving in the VR game was somehow too slow, while they preferred the teleporting functions.
- Making the VR scenarios more coherent with the story: some participants asked for improvement in the coherence of the 3 VR missions' environments with the space adventure game plot by introducing relevant objects and characters in each of the game missions.
- Improving engagement and game dynamics in the VR game: most participants wanted to be provided with more engaging challenges in the game missions by including more interactive objects and characters, brighter colors, relevant music and sounds, and clear feedback to support progress toward the achievement of the game objectives.

Following stakeholders' indications (including both the facilitators and the adolescents involved in the explorative study), improvements were implemented in the final release of the Zentastic game; for example, the 3 game missions were enriched by improving their interactive quality and overall coherence to the space challenge. We also designed and integrated a clearer scoring system within the game missions to provide feedback to participants during the game and facilitate an easier functional assessment of the players' performance and targeted behavior by therapists during and after the game session.

We added specific controls for the facilitator in the VR game, allowing for a smoother personalization of the playing experience according to the level of complexity and ensuring the engagement of participants over multiple sessions in the VR game.

However, as the user sample used for this explorative study only partially fits the age of the target user group and the evaluation was based on an early prototype of the game, it was necessary to carry out an additional study with adolescents with ASD (aged 13-18 years) to evaluate the suitability of the experience. Nonetheless, such evaluation allowed us to ensure that our design was sufficiently usable and engaging for adolescents to support a multisession gaming intervention. This aspect is particularly relevant when designing for adolescents with ASD as VR game experiences not fitting their expectations and preferences may drastically reduce their motivation to engage with such experiences, as well as impair the overall effectiveness of such training interventions.

Table 3. Participants' difficulties experienced with the virtual reality gaming environment on a scale of 1 to 5 (1=not at all; 5=very much) in the explorative study.

Factor measured	Score, mean (SD)
Difficulty with Oculus headset	2.3 (1.2)
Difficulties with controllers	2.5 (1.4)
Nausea	1.7 (1.1)

Mixed Methods Study: Participants and Method

This section presents the study conducted to evaluate the feasibility of our VR game for training social skills in adolescents with ASD and the main results achieved.

We conducted an observational study on the interaction of 12 boys with ASD [20] (mean age 13.9, SD 3.1 years) with the final version of the Zentastic VR game. All participants could use the computer and internet and had prior experience of playing digital games (see Textbox 2 for inclusion criteria). The goals of the study were to evaluate the acceptance and enjoyment of the game [19,21] and to investigate whether it facilitated the targeted behaviors contributing to enhancing adolescents' social skills.

The study was carried out at the Cooperativa Albero Blu Center premises for >1 month.

Textbox 2. Inclusion criteria to select participants.

The participants must

- be aged between 13 and 18 years
- be diagnosed as having autism spectrum disorder (ASD; without intellectual impairment) using standard instruments from the Diagnostic and Statistical Manual of Mental Disorders-5 criteria, with Autism Diagnostic Observation Schedule module 3 having a severity level of at least 4 (within the ASD range spectrum)
- have a cognitive capacity of >70 as measured by the standard Wechsler Intelligence Scale for Children (fourth edition) [27]
- sign the consent form to participate in the study (applies to both the parent or tutor and the adolescent)

The participants played the VR game in groups of 2 to 4 players per session, assisted by the facilitator. Each adolescent participated in 3 sessions, scheduled weekly.

Each session lasted for 45 minutes, during which adolescents were first introduced to the game by the facilitator. Before the study launch, the researchers provided the facilitators with a dedicated training session on the use of the VR game controls and a prescripted document of guidelines to follow during the game sessions to ensure a consistent deployment of the game intervention among the different facilitators involved.

The methods used to assess the feasibility of the VR game were as follows:

- Participants' score on the Social Skills Questionnaire (SSQ [28]), Teacher form, filled out by their therapist before and after the intervention in VR
- Postsession observations on the targeted behaviors exhibited by adolescents during the VR game to assess the effect of the game on training social skills
- An ad hoc user experience questionnaire and semistructured interview administered to participants after each session to collect feedback on their satisfaction with the VR game and suggestions for improvements (Multimedia Appendix 1).

Each session involved the presence of an expert observer positioned in front of the users, whose task was to record the behaviors exhibited by the participants during the VR activity. At the end of each session, the observer and therapist would jointly fill out a specially prepared observation form, recording the observed behaviors.

In addition, each session was video recorded, which allowed for the review of the sessions and further coding of the participants' behavior.

Ethics Approval

The study was approved by the research ethics committee of Azienda Provinciale Servizi Sanitari, Trento on March 15, 2023 (report 4959).

Results

Social Skills Questionnaire

A comparative analysis of the pre- and postintervention SSQ responses (Teacher form) for matched participants was performed using the Wilcoxon signed rank test. This test was used to examine the statistical significance of the improvement in social and communication competence of the participants based on the aggregated data of the 12 participants. Wilcoxon signed rank tests determined that there was a statistically significant median increase (W=1, P=.008; critical value of W=1 at n=8) between pre- and postintervention scores, indicating that the participants showed significantly higher frequencies of positive social interaction and communication competence after the intervention.

Postsession Observations

Postsession observations by the therapist were mainly oriented toward understanding the behaviors exhibited by the participants during the VR game sessions to identify possible usability issues. Different behaviors were considered to gather information about the user experience with the VR game, including (1) qualitative measures of participants' adaptation and engagement with the game, (2) a systematic evaluation of participants' interactions and communication, and (3) an assessment of participants' emotional states during the activities.

Overall, all the participants displayed a natural curiosity and interest in the experience, which further grew over time. This observation was supported by various qualitative indicators, including positive and enthusiastic expressions (both verbal and nonverbal) during the tasks as well as during active engagement.

During the game sessions, most participants actively shared their improvements, difficulties, impressions, and questions with other players and, particularly, with their facilitators. The collaborative interactions among the participants increased as the game missions progressed (Figure 1; Table 4).

We observed a growth in self-confidence among the participants throughout the game missions, as suggested by a gradual increase in the level of engagement with the activities as well as a decrease in adaptive distress in VR scenarios and visuospatial difficulties when interacting with the virtual surroundings (Figure 1; Table 4). Initially, they primarily focused on following the game missions and did not fully explore the virtual environment. However, gradually, they started venturing into the game scenario, comprehending its dynamics and, most importantly, feeling increasingly capable and secure.

The first mission (Coin Hunt) emphasized collaboration and communication among the participants, whereas the third mission (Planet Battle) actively engaged the participants to a greater extent than other missions. It is possible that these results were influenced by the game dynamics. Coin Hunt offered a lesser challenging and emotionally impactful setting than other missions. Thus, this environment might have facilitated increased social interactions among participants as they worked together to complete the task. By contrast, according to participant reports, Planet Battle was the most enjoyable game mission, which increased participants' motivation and engagement.

Overall, the participants successfully completed all game sessions, consistently achieving high scores. Notably, their game scores showed a clear upward trend across the sessions, even if the difficulty level was progressively increased by the facilitators.

Figure 1. Participants' behavioral assessment (first part) during the virtual reality (VR) gaming missions, expressed on a scale of 1 to 5 (1=low; 5=high).

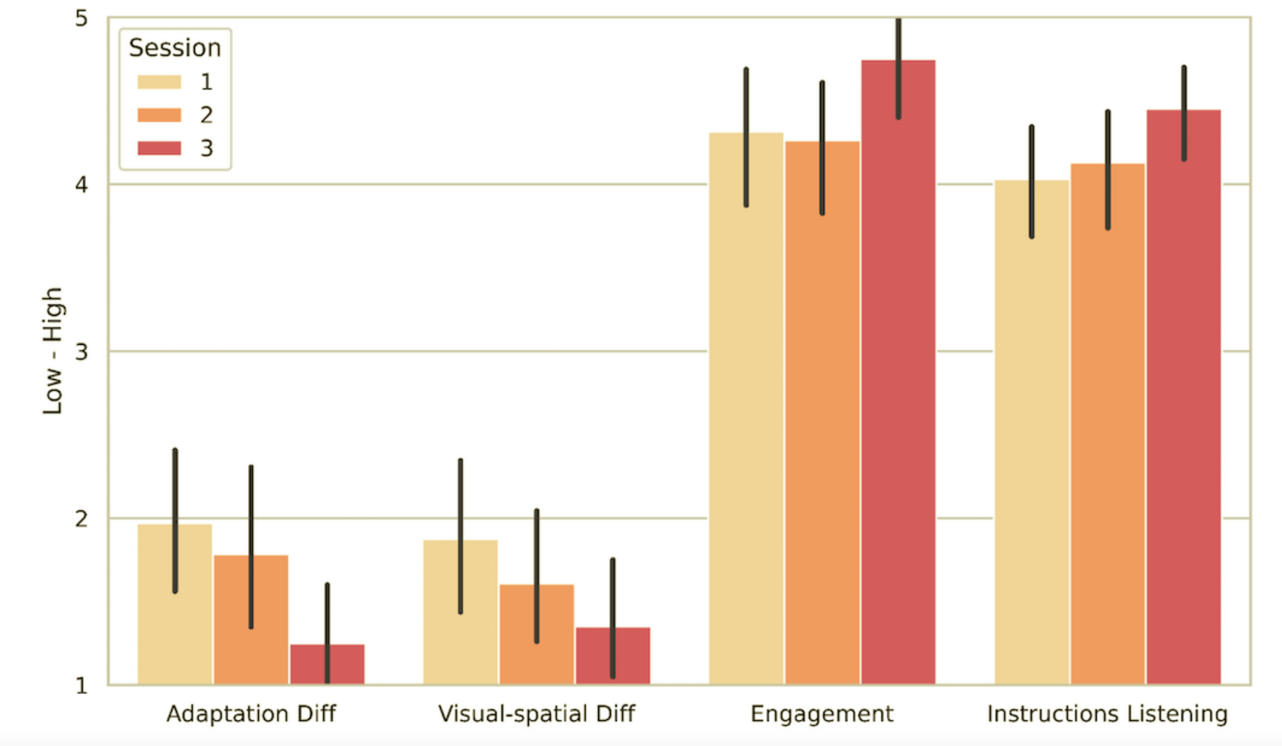

Table 4. Participants' behavioral assessment (first part) during the virtual reality (VR) gaming missions, expressed on a scale of 1 to 5 (1=low; 5=high).

Feature	First mission, mean score (SD)	Second mission, mean score (SD)	Third mission, mean score (SD)
Difficulties in adapting to VR	2.0 (1.3)	1.7 (1.2)	1.3 (0.7)
Visuo-motor difficulties	1.9 (1.3)	1.6 (1.0)	1.4 (0.8)
Listening to instructions	4.0 (1.0)	4.1 (0.9)	4.5 (0.6)
Engagement with the game	4.3 (1.2)	4.3 (1.0)	4.8 (0.7)

In addition, to obtain a more systematic measurement of the social patterns displayed during the VR activities, we quantified the number of social exchanges. The group social behaviors considered were social initiations and social responses to peers. Moreover, we differentiated between spontaneous social exchanges and prompted social exchanges. Spontaneous social exchanges included initiations and responses manifested spontaneously by the participant toward peers. By contrast, prompted exchanges included initiations or responses that were not spontaneously manifested by the participant but were solicited by the therapist through verbal cues. This differentiation allowed us to distinguish social exchanges based on spontaneity and to analyze any differences between activities. Furthermore, we noted the number of times each participant requested a break during the game. We quantitatively compared the distributions of these parameters among the 3 game missions using the Kruskal-Wallis test. Our results indicated a significant difference in both spontaneous (H_2=49.6, *P*<.001) and prompted (H_2=14.8, *P*<.001) social initiations and spontaneous (H_2=43.3, *P*<.001) and prompted (H_2=11.6, *P*=.003) social responses, with the first mission exhibiting higher scores than the subsequent ones. In addition, the number of requested breaks was significantly higher in the first mission, confirming that Coin Hunt is the most socially promoting activity. The collaborative and communicative nature of the gameplay is reflected in the higher number of social initiations and responses observed during this mission. Moreover, a higher need for breaks during this game mission by users corroborates this analysis, highlighting the critical role of appropriate social interaction modes for individuals with ASD. To gain a broader perspective on the nature of these results, we compared the ratio between spontaneous and prompted social exchanges. Our analysis of the distribution of spontaneous and prompted initiations and responses using the Mann-Whitney test revealed that the participants showed a significantly greater number of spontaneous social openings (mean 12.9, SD 11.4) than prompted social openings (mean 0.7, SD 1.2; *U*=76.0, *P*<.001) and a higher number of spontaneous social responses (mean 11.8, SD 0.6) than prompted social responses (mean 0.3, SD 0.6) to peers (*U*=74.5, *P*<.001), emphasizing the effectiveness of the game missions in promoting spontaneous group interactions.

To obtain a more systematic measurement regarding the participants' emotional state, we classified the gaming sessions by qualitatively indicating the nature of the activation state during the VR experience. The emotional state was encoded in agreement with 3 independent evaluators using 2 distinct parameters. The first parameter coded the level of activation and was characterized as calm, agitated, or dysregulated. The second parameter referred to the level of participation in the activity and was classified as active or passive. The results indicated that 75% (9/12) of the players approached the activity calmly, while only 25% (3/12) manifested episodes of agitation, and none of the participants became dysregulated during the activities. Moreover, >86% (10/12) of the players participated actively in the scenarios, whereas only 14% (2/12) showed a passive attitude. Overall, the participants maintained a positive attitude during the game sessions, demonstrating collaboration and maintaining a high level of attention and activity. Moreover, the analysis showed a low level of frustration experienced by most participants. We observed 9 episodes of frustration during the first mission (mean 1.6, SD 0.5), 2 episodes during the second mission (mean 1.5, SD 0.5), and 1 episode during the last mission. The observed results could indeed be attributed to increased participant familiarity and adaptation throughout the different missions, both in terms of knowledge of the VR game and the ability to use the controllers. As participants progressed through the game missions, they likely became more comfortable with the VR environment and developed better skills in using the controllers. This increased familiarity and skill level may have contributed to the decrease in frustration episodes during subsequent missions. These results confirmed that the VR game provides a controlled and safe environment that supports skills training.

Results of the Interviews With the Participants

The interviews with participants at the end of the VR gaming experience were mainly oriented toward evaluating whether the VR gaming experience met the participants' expectations and identifying possible usability issues. Different questions were used to gather information about user experience with the VR game. The results from the rating on a Likert scale (1=not at all; 5=very much) showed an overall appreciation of the VR game user experience by all participants (12/12, 100%), who found the VR game easy to use, clear, and engaging (Table 5), with no participants reporting interaction issues or discomfort with the VR game (Table 6).

To further confirm this positive experience of participants with the VR game, we asked them to express their willingness to play again with it after the end of the intervention (Table 4). All the participants (12/12, 100%) were willing to play again, and 92% (11/12) of them reported experiencing positive feelings, such as happiness and relaxation, during the VR gaming session and at the end of the intervention.

Table 5. Participants' appreciation of the virtual reality (VR) gaming environment on a scale of 1 to 5 (1=not at all; 5=very much) in the feasibility study.

Factor measured	Score, mean (SD)
Clarity of VR game	4.5 (0.5)
Engagement	4.8 (0.3)
Interaction with objects	4.3 (1.1)
Movement in VR	4.9 (0.2)
Object grasping	4.6 (0.4)
Interaction with the environment	4.7 (0.4)
Focus on activity	4.8 (0.3)
Enjoyment	4.7 (0.4)
Willingness to play again	4.8 (0.3)

Table 6. Participants' difficulties experienced with the virtual reality gaming environment on a scale of 1 to 5 (1=not at all; 5=very much) in the feasibility study.

Factor measured	Score, mean (SD)
Difficulty with Oculus headset	1.1 (1.5)
Difficulties with controllers	1.3 (0.6)
Nausea	1.0 (0.2)

Discussion

Principal Findings

The feasibility study with 12 adolescents with ASD showed a good level of acceptance of the VR game intervention, and several targeted behaviors related to social interaction were observed. Although the findings of this study have an exploratory nature, they can help guide the future design of VR game interventions that foster social skills training in adolescents with ASD. In particular, as shown in previous work [19] the design of a cooperative model for the game mechanics helped to sustain the motivation and engagement of players over the VR gaming sessions and to promote the triggering of social behaviors. This finding is also aligned with the recent studies highlighting the social motivation explanation of ASD [29], such as the importance of learners' motivation or agency in social engagement and interaction performance. An implication is that VR-based training activities differ in their social affordance and should be selected and designed in alignment with the learner and learning needs to promote a comprehensive set of social skills [16]. In accordance with previous studies [30-32], the findings from our observations during the game sessions highlight the significance of maintaining a balance between serious content and game elements in serious games designed for individuals with ASD. Moreover, our positive findings in terms of participants' success in completing the game missions and achieving their objectives suggest a potential alignment between the participants' skill levels and the challenges presented in the game; this indicates a promising match between their abilities and the game's demands [33]. Overall, we can confirm that the deployment of an inclusive co-design method during the Zentastic game development facilitated a successful merging of therapists' knowledge and expertise with adolescents' requirements and preferences for VR gameplay, ensuring their motivation to engage with the game over multiple sessions to train their social skills in a positive and safe VR environment.

Limitations

This study contributes new knowledge to the inclusive co-design of VR gaming solutions for the training of adolescents with special needs; this domain of design and research is still understudied, often omitting to include the views of the key stakeholders involved in the adoption of such solutions. However, some limitations are still present.

First, the sample of participants involved in the iterative design process was rather limited, which implies that the results of our feasibility study should be interpreted with caution. Future applied research to study the effectiveness of VR gaming environments for training social skills should involve a larger sample of target users and control groups with a systematic research design. In addition, the number of female participants involved was very small, and this might have affected our design, which better represented the preferences and interests of male adolescents.

Another limitation of the feasibility study conducted is the lack of control for history effects that might be coincidental with the intervention deployment, so we cannot derive final conclusions in terms of social skills training outcomes determined by our VR game intervention. However, our results can inform future research that is needed to further assess the transferability of the social skills trained in the VR game to everyday settings, as well as the long-term deployment of the VR game intervention in natural, formal, and informal learning environments, including, for example, remote access to the VR game from home. Another interesting question to be addressed by our own and future design-based research is regarding the effect of different design and implementation features of VR game interventions for training social skills of adolescents with ASD, so that we can support their long-term training in VR with a more diversified range of missions targeting additional behavioral skills.

Conclusions

Overall, the results of our feasibility study showed that playing the Zentastic multiplayer VR game had a positive effect on supporting the enhancement of social skills and competence in adolescents with ASD, as evidenced by the results of the SSQ scores before and after intervention. Data collected from the postsession observations by therapists and from the interviews with participants further confirmed the value of the VR game in terms of user engagement, safety, and well-being during the training activities in VR; this would encourage the future application of VR gaming solutions for the training of adolescents with ASD and, potentially, other neurodevelopmental disorders. Even if further research is necessary to validate these results, these initial findings could be considered as promising indications of the usefulness of adopting an inclusive co-design approach when developing VR gaming solutions for the training of skills in this target population.

Acknowledgments

This research was funded by European Institute of Technology (EIT) Digital (grant 22124 XR4A; extended reality–enabled social skills therapy for adolescents with autism and neurodevelopmental disorders). The authors wish to thank the therapists and adolescents who participated in this study.

Authors' Contributions

SG, MC, and ES designed the study; ES and OMI acquired funding; MC and MD supervised the study recruitment and game implementation; and SG and ES coordinated the research activities. EV, GA, AB, and PV provided intellectual input to the game and study design. SG and AB led ethics approval. MC and EV led the study recruitment and data management. SG, MC, GA, and EV performed data analyses. SG drafted the manuscript and incorporated feedback from coauthors. All coauthors revised and approved the submitted manuscript.

Conflicts of Interest

ES, MC, and MD are cofounders of Meeva Srl. All other authors declare no conflicts of interest related to this study.

Abstract

Background: In the context of training specialist nurses and nursing education, a game-based mobile app was used as a simulation to teach intensive critical care specialist nurses the knowledge and skills of extracorporeal membrane oxygenation (ECMO) pipeline preflushing.

Objective: This study aimed to evaluate the impact of a game-based mobile app on improving ECMO pipeline preflushing skills in intensive critical care specialist nurses.

Methods: A total of 86 intensive critical care specialist nurses who were learning ECMO for the first time were included in this study. The nurses were divided into 2 groups: a control group (n=43) and an experimental group (n=43). Participants in the experimental group used a game-based mobile app for simulation exercises; the control group received no additional intervention. All participants took a theoretical test and a skill operation test at the beginning of the study and 1 week later. The differences in scores between the 2 groups were compared, and the learning curve of the experimental group was observed.

Results: The final theoretical test scores (88.44 and 85.02) and skill operation test scores (89.42 and 86.33) of the experimental group and control group, respectively, were significantly higher than those of the initial tests (theoretical test scores: 75.88 and 74.42; skill operation test scores: 75.44 and 75.93; all $P<.001$). The scores of the final theoretical test (88.44) and the final skill operation test (89.42) in the experimental group were higher than the scores of the control group (85.02; $P<.001$ and 86.33; $P<.001$, respectively). Learning curve analysis showed that the experimental group needed an average of 17 operations to master the skill.

Conclusions: This study suggests that a game-based mobile app may be more effective for intensive critical care specialist nurses in ECMO pipeline preflushing education than traditional Chinese lecture-practice education.

extracorporeal membrane oxygenation; mobile app; simulation training; specialist nurses; learning curve; ECMO; intensive care

Introduction

Extracorporeal membrane oxygenation (ECMO) is a treatment that uses an improved extracorporeal circulation system to provide temporary life support for patients with potentially reversible heart or respiratory failure [1]. ECMO achieves the purpose of lung or heart recovery from disease by providing a mechanism for gas exchange and heart support. With the continuous development of ECMO-related technologies, it has become a recognized treatment method for neonates, children, and adults who do not respond to conventional medications for respiratory failure and heart failure. According to statistics, among 1099 patients with COVID-19 in China diagnosed between December 2019 and January 29, 2020, a total of 55 patients entered the intensive care unit for treatment, 67 patients underwent invasive mechanical ventilation, and 5 patients received ECMO treatment [2]. During the new coronary pneumonia epidemic, the application of ECMO played an important role during the treatment of patients who are critically ill. Despite major advancements in technology, ECMO is still associated with high morbidity and mortality [3,4], with nosocomial infections being the leading causes, including ventilator-associated pneumonia (57.6%), tracheobronchitis (9.1%), bloodstream infections (9.1%), skin and soft tissue infections (9.1%), and cytomegalovirus reactivation (9.1%) [5]. Although the occurrence of these complications is not necessarily directly related to improper pipeline preflushing, if medical staff do not follow the correct sequence of steps and do not observe the principle of sterility, it may lead to an increased risk of complications. Therefore, it is necessary to train intensive critical care specialist nurses on ECMO.

In recent years, to compensate for the shortcomings of traditional education models, such as classroom teaching and group exercises, and to improve teaching quality, education in the field of medicine and health has continuously sought more innovative models and methods. More and more educators are applying game teaching to medical field teaching. For example, Tan et al [6] applied games to blood transfusion teaching and found that they had a positive effect in improving nursing students' knowledge and confidence in blood transfusion practice. Researchers used video games to simulate nursing and medical students' first visit to the operating room in hopes of improving perception and performance and reducing stress [7]. In addition, a serious game was used to supplement the teaching of cardiopulmonary resuscitation (CPR) [8]. This game could simulate emergencies in a 3D virtual environment. Participants must apply CPR to rescue an injured patient. The use of this game improved students' CPR knowledge and skills [8]. At present, there are few innovative education studies on ECMO and its pipeline preflushing; they mainly consist of the combination of education using high-fidelity simulation and augmented reality (AR) technology. Researchers have carried out high-fidelity simulation education and training courses for intensive critical care specialist nurses, improving their personal skills and the skill level of the whole team [1,9]. There was also great potential for improving the effect of ECMO intubation training based on AR instructions [10]. However, due to the high cost of training using the abovementioned teaching methods or techniques, and limited by the training venue and practice time, students usually do not have enough time to practice and cannot check the learning practice results in a timely manner.

The traditional ECMO training method mainly consists of students or nurses passively accepting theoretical explanations and technical operation demonstrations. The training method is simple and lacks innovation, and the training process does not evoke enthusiasm and participation from the trainees. In addition, the traditional ECMO training method, including high-fidelity simulation and AR technology education, limits the time and place for nurses to perform operational exercises [1,9]. To our knowledge, there have been no studies on the use of games in ECMO education or ECMO pipeline preflushing teaching. Therefore, this study integrated games into traditional clinical teaching methods and developed a game-based mobile app of ECMO pipeline preflushing, which enables intensive critical care specialist nurses to master the relevant technologies; at the same time, the app can become a tool for nurses to learn relevant knowledge and test learning results anytime and anywhere. We explored whether a game-based mobile app affected the practical knowledge and skill levels of intensive critical care specialist nurses. At the same time, combined with the learning curve, we analyzed the minimum number of operations intensive critical care specialist nurses needed to master this operation, to provide a reference for formulating more standardized training and guiding ECMO education in the future.

Methods

Participants

The study population included 86 nurses who were undergoing targeted training as intensive critical care specialist nurses at a university-affiliated hospital in China.

The inclusion criteria for this study consisted of the following:

- Having a mobile phone or computer
- Having internet access
- Having obtained the intensive critical care specialist nurse certificate but no previous experience in ECMO

The exclusion criteria for this study consisted of the following:

- Having participated in at least 1 theoretical lecture, demonstration, or group study on ECMO
- Have not undertaken the first or final theoretical and skill performance assessments of ECMO pipeline preflushing

Based on the experimental results, the researchers determined that the required number of nurses was at least 68 intensive critical care specialist nurses (34 in the experimental group and 34 in the control group). A total of 86 participants (43 in the experimental group and 43 in the control group) were included in the study due to an expected loss of 10% to 20% of the sample during follow-up.

We used convenience sampling methods to select intensive critical care specialist nurses from 2 districts (the eastern district and the western district) of a university-affiliated hospital in China as the research participants. Among them, those from the western district were used as the experimental group, and those from the eastern district were used as the control group. We registered the participants' details and kept the group information confidential. Before completing the training and evaluation, the trainers and participants were not informed of the group allocation.

Ethical Considerations

This study was approved by the Medical Ethics Committee of the Affiliated Hospital of Qingdao University, where the researchers are located. In this project, the rights and interests of the participants were fully protected, and the research protocol was approved in accordance with the requirements of the Medical Ethics Committee (approval number: QYFYWZLL26706). In this study, all participants provided informed consent, and participants reserved the right to withdraw at any time. During data collection and analysis, the data were anonymized, and only a number was used to match the results of each test. No other form of compensation was provided to the participants in this study.

Procedures

The study was conducted from March 8, 2021, to March 18, 2021. To prevent interaction between the 2 groups, intensive critical care specialist nurses from 2 different districts of the same general hospital were selected for the study. The 2 districts are located on opposite sides of Jiaozhou Bay, 40 km apart. The same management team was responsible for the management and training of the 2 groups.

On March 8, 2021, all intensive critical care specialist nurses conducted a 1-day theoretical training in the Shinan district of this general hospital. The training content referred to the *ECMO Manual* (2nd edition; Chinese version) [11] and *ELSO Guidelines for Training and Continuing Education of ECMO Specialists* [12], including the principles and indications of ECMO, contraindications, equipment and consumables, pipeline preflushing, etc. Subsequently, all intensive critical care specialist nurses underwent 2 days of skill training and practice. The skill training corresponded to the content of theoretical training. After the 3 days of on-site intensive training, the first theoretical and skill tests were immediately carried out. The intensive critical care specialist nurses who participated in the tests were not known to the examiners; they knew only that all participants had received training on ECMO.

Next, we downloaded the game-based ECMO pipeline preflushing mobile app onto the mobile phones of the intensive critical care specialist nurses of the experimental group, explained that they could play the game anytime and anywhere in the next 7 days, and asked them to use and complete the program more than 30 times. Within 7 days after the first evaluation, the control group received no additional intervention measures. Seven days after the intervention measures were implemented, the 2 groups of participants were again assessed on theoretical knowledge and skills.

Preparation of the Game-Based Mobile App

The game-based mobile app was designed and developed by a team of authors, including 6 nursing administrators with more than 10 years of clinical teaching experience, 10 clinical teachers, 1 software engineer, 1 technical support staff, 1 artist, and 1 graduate nurse. The software research and development team made reference to previous literature—based on the training of applied skills in nursing and combined with clinical teaching experience, gamification teaching theory, and the use of virtual clinical resources as the carrier—and simulated a clinical operation with high adaptability [13]. The researchers designed an “ECMO Pipe Preflushing Skill List” based on the *ECMO Manual* (2nd Edition; Chinese version) [11] and used it to create a game scene including pictures and animations. The researchers used the C++ programming language, which can be used to write a working system language or application programming languages [14], and the Cocos2D game engine to develop the game-based mobile phone app [15]. During software development, the team was responsible for overall coordination, supervision, management, and quality control, and they recorded, summarized, and organized the data for the entire process. This app was reviewed by professionals with a medical background. Since the software works with any Android operating system, the app can be played anywhere without an internet connection. Nurses start the game by registering with their phone number, but at first, they need to be connected to the internet to download the game.

According to the sequence of operations, the game was divided into 7 stages with a total of 61 steps:

- Stage 1: Preparing items and materials according to the detailed list (13 steps)
- Stage 2: Checking supplies (5 steps)
- Stage 3: Connecting and installing pipelines (12 steps)
- Stage 4: Using gravity to preflush the front membrane pipeline (4 steps)
- Stage 5: Using the machine to exhaust the gas after the membrane (17 steps)
- Stage 6: Stopping the pump, clamping the pipeline, and removing the pipeline (7 steps)
- Stage 7: Connecting the air-water cycle (3 steps)

The steps for users to use the game-based mobile app are as follows. The user logs in using the registered mobile number and password; the log-in screen is shown in Figure 1. After entering the game interface, the user first needs to select the “steps” box at the bottom left of the game interface. At each step, the user need to place the cards at the bottom right of the game screen into the green boxes at the top right of the screen in the correct order. An example of the game-based mobile app is shown in Figure 2. If the user places a card in the correct position, the card remains in the box, and when the positions of all the cards and green boxes are correctly aligned, then the next step can be entered. If the card is placed in the wrong position, it will bounce back to its original position, and the flower in the lower left corner will drop a petal. The flower has 9 petals; when all the petals have dropped, the game results in failure, and the “game failure” interface is shown (Figure 3). If the user completes all the steps before all the petals fall off, the game is successful, and the “game success” interface is shown (Figure 4).

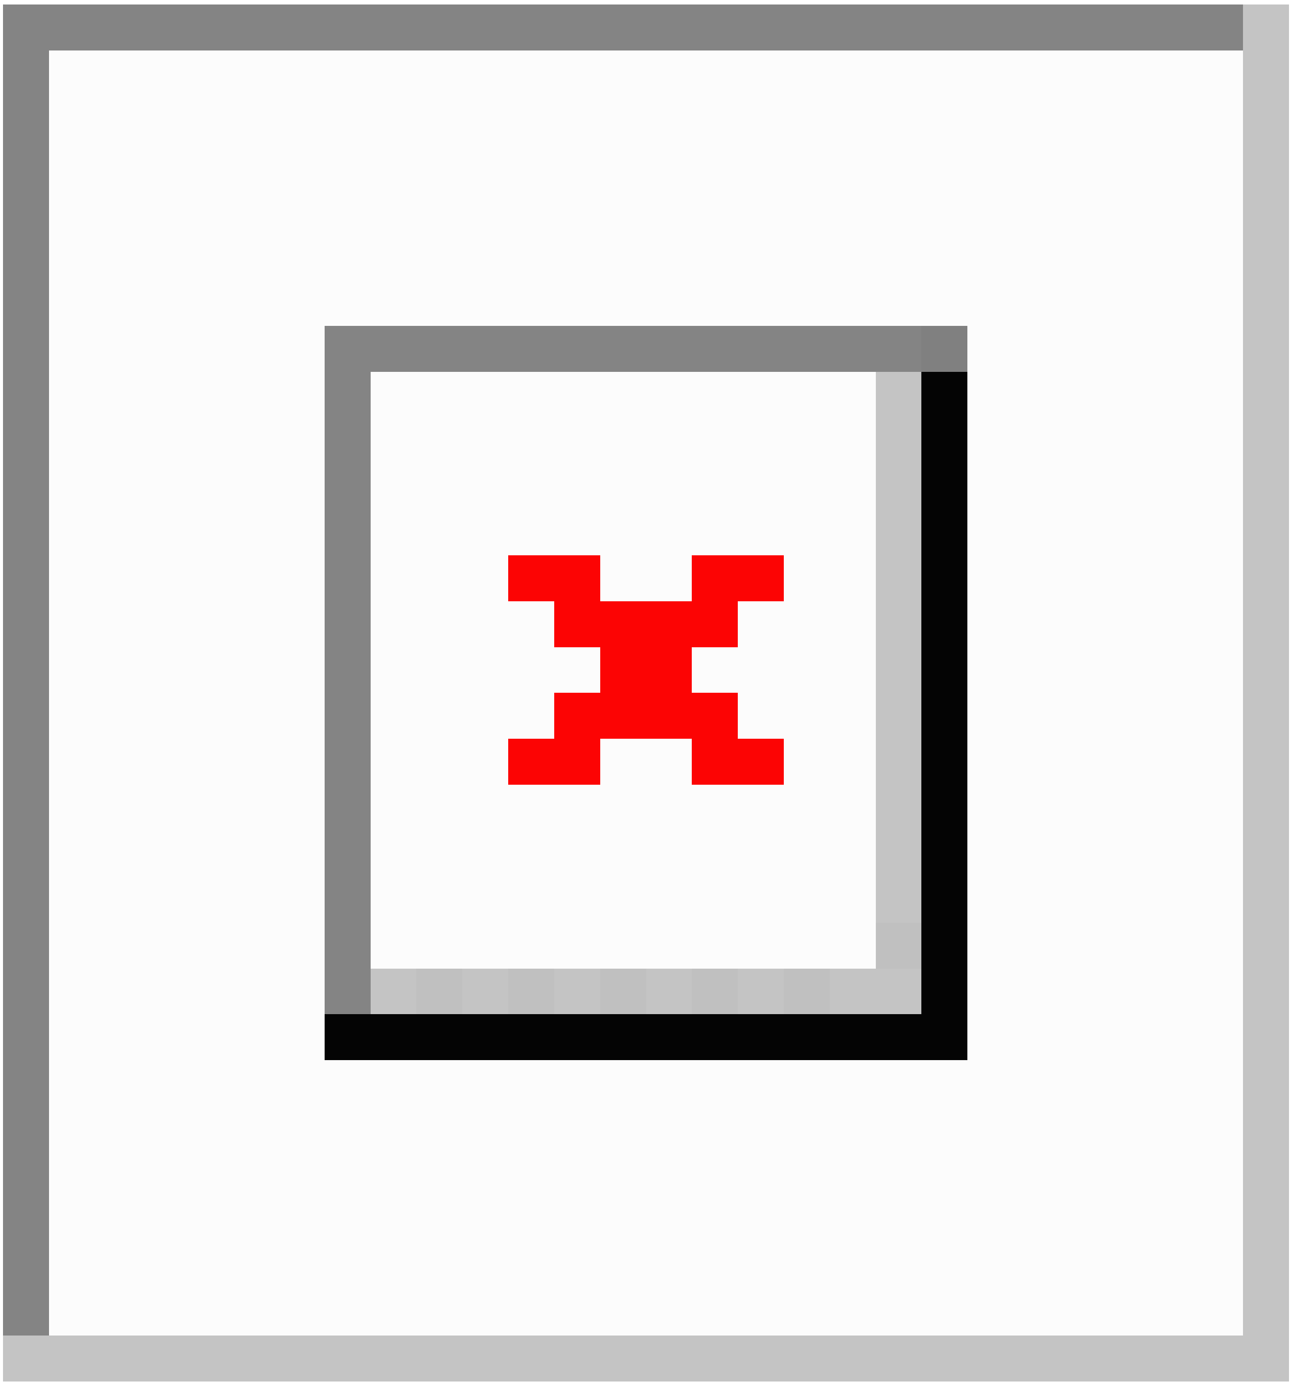

Figure 2. An example of the game-based mobile app. ECMO: extracorporeal membrane oxygenation.

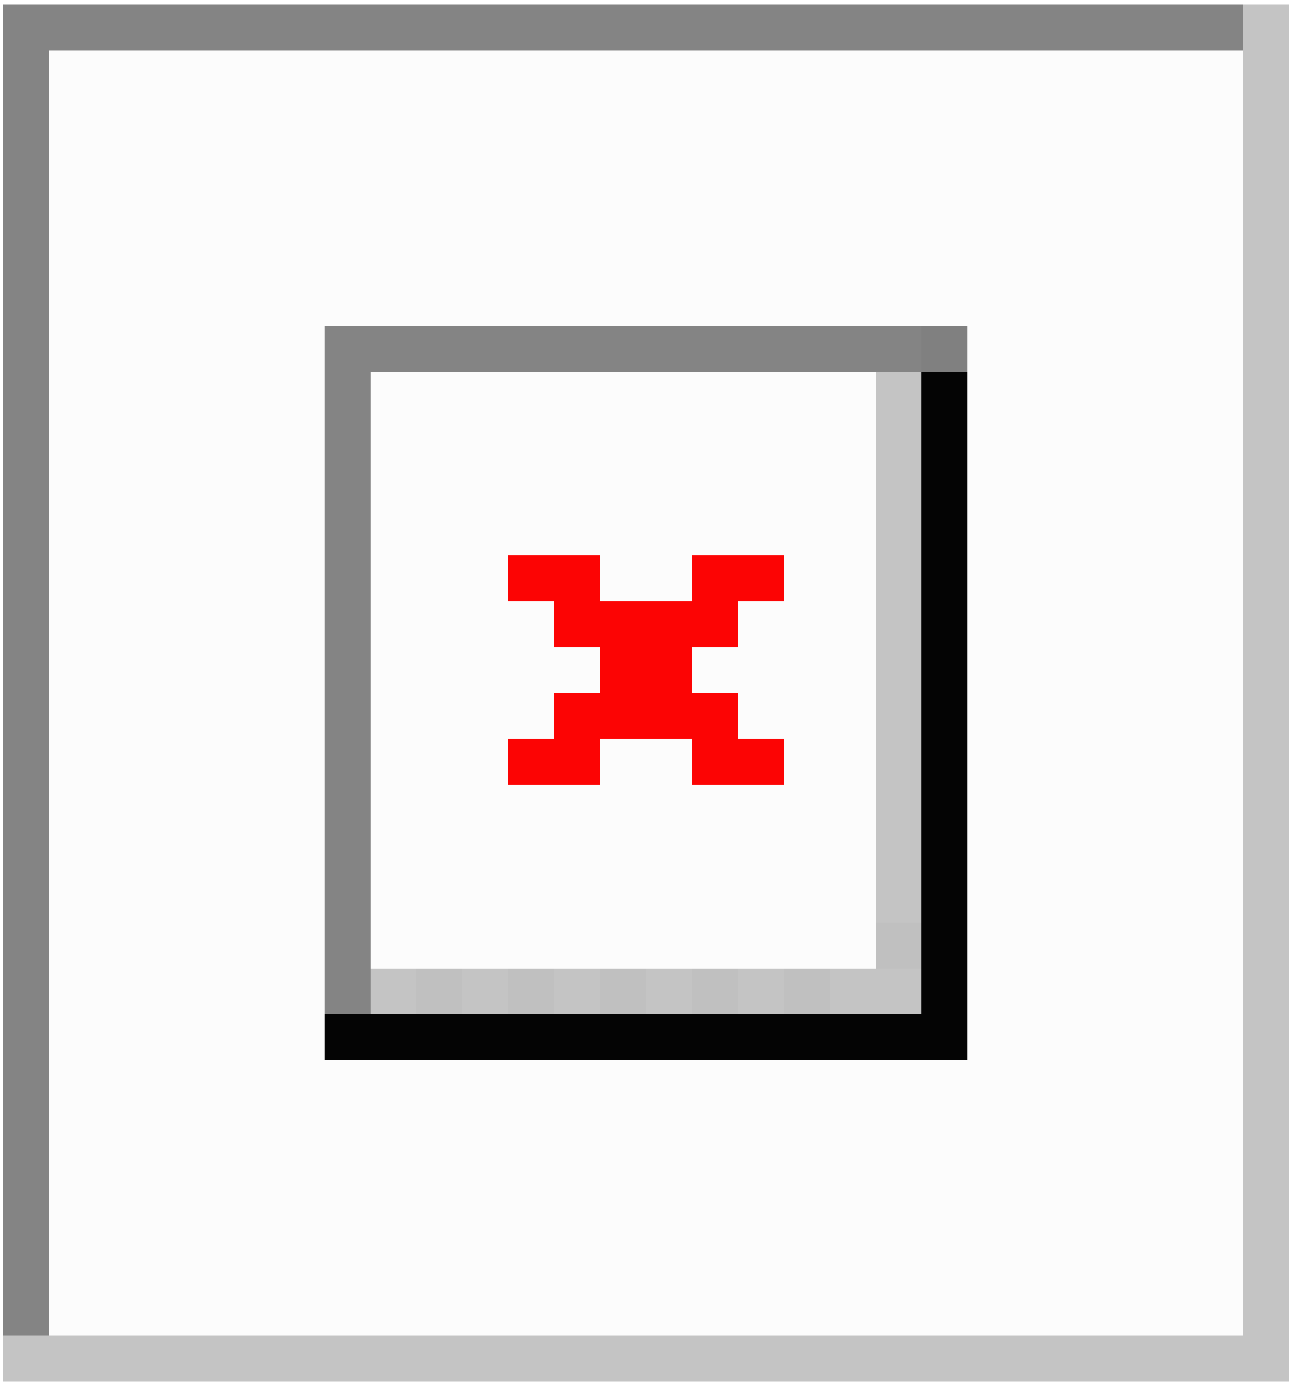

Figure 3. Screenshot of the interface at the end of the game when the user fails.

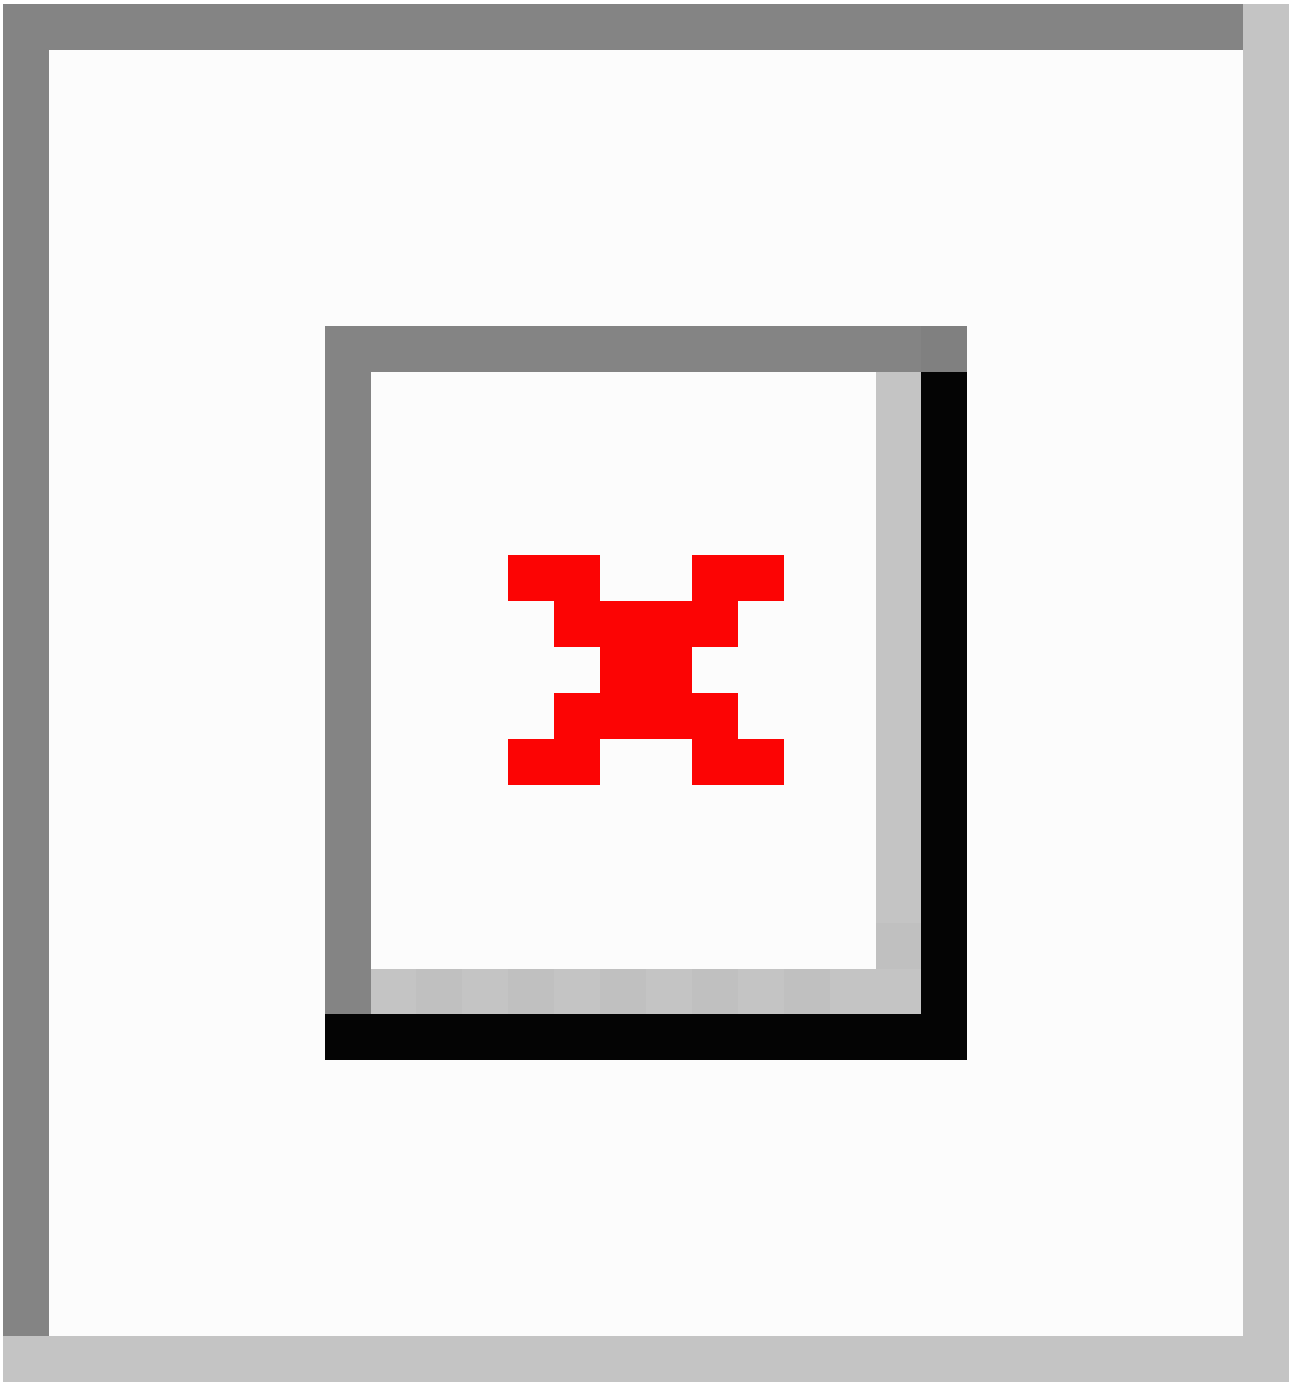

Figure 4. Screenshot of the interface at the end of the game when the user succeeds.

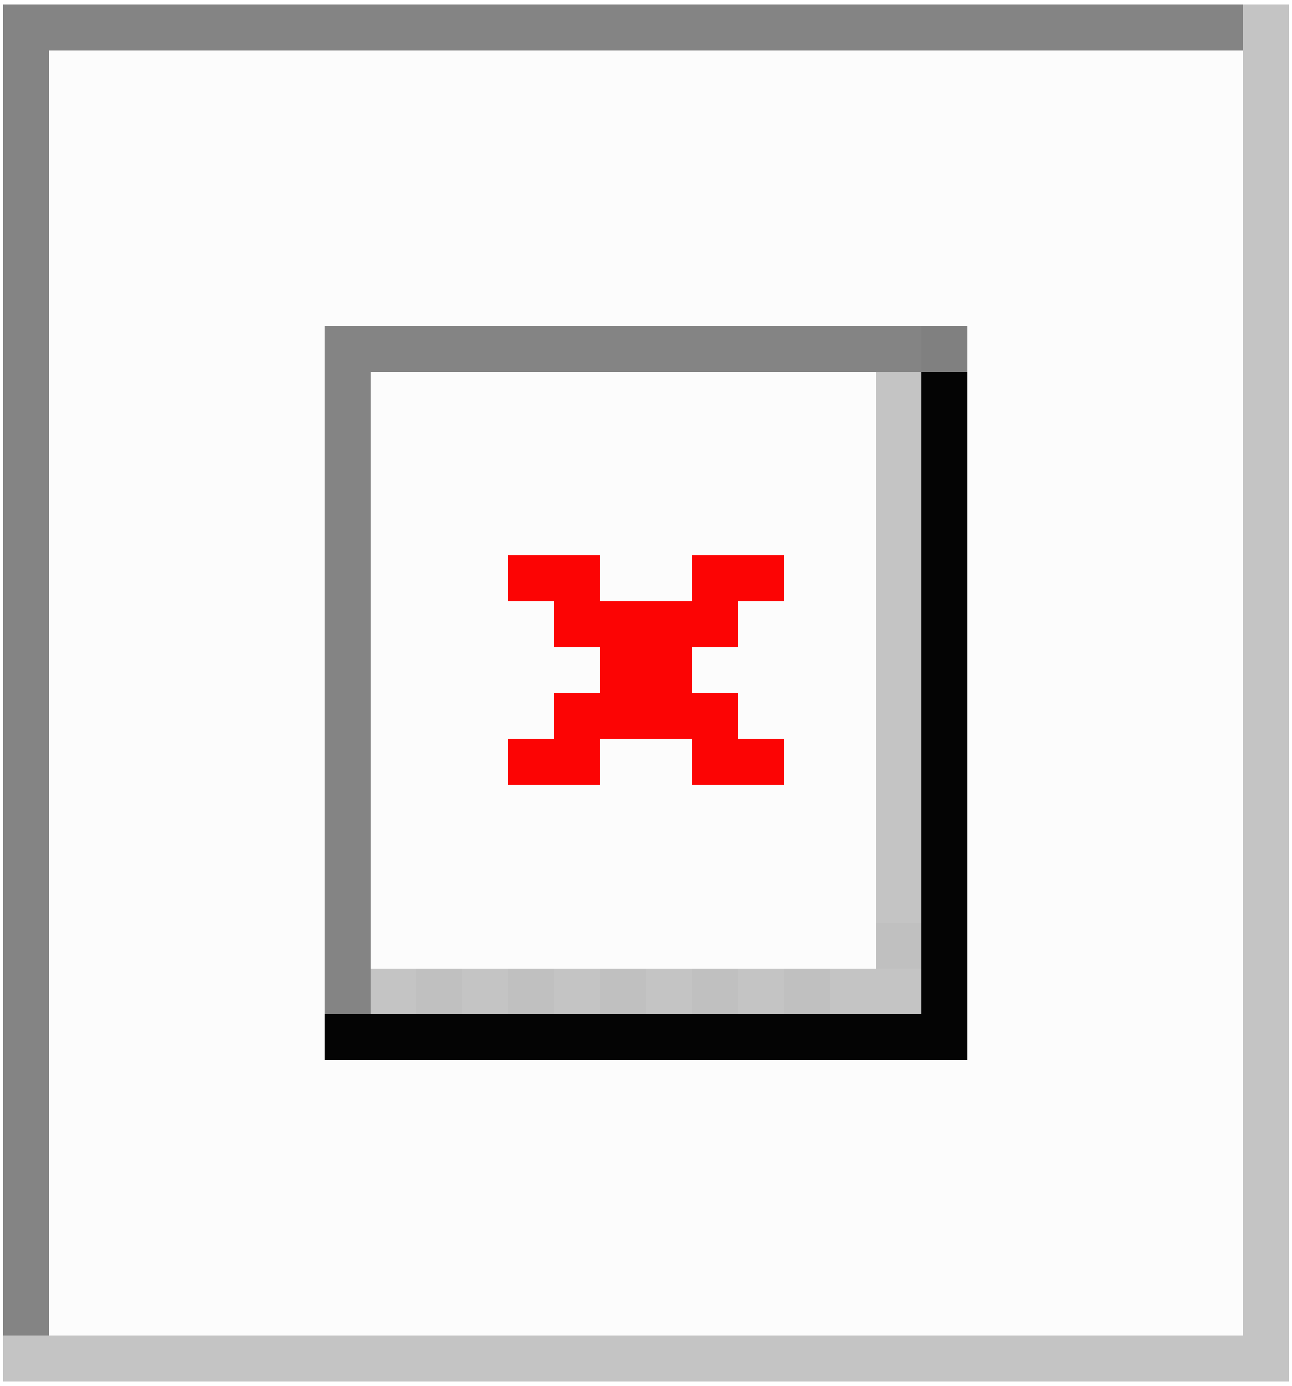


Data Collection Tools

Demographic Questionnaire

A descriptive characteristics questionnaire with 5 questions was used to collect data, including sex, age, education, job title, and the number of working years.

Skills Evaluation Tool

The ECMO Pipeline Preflushing Theoretical Scale and ECMO Pipeline Preflushing Skills Scale were used to assess the participants' mastery of theoretical knowledge and practical ability. We referenced the *ECMO Manual* (Chinese version; 2nd edition) [11] and *ELSO Guidelines for Training and Continuing Education of ECMO Specialists* [12] when designing these scales. The 2 scales were evaluated by 12 specialists in the field of acute and critical care and nursing education with a title of deputy senior or higher and with at least 15 years of work experience. When the content validity index–individual items (I-CVI) of a scale is >0.78 and the content validity index–overall scale (S-CVI) is >0.9, the content validity of the scale is considered good [16]. The I-CVI of the ECMO Pipeline Preflushing Theoretical Scale was 0.83, and the S-CVI was 0.91. The I-CVI of the ECMO Pipeline Preflushing Skills Scale was 0.83, and the S-CVI was 0.94.

ECMO Pipeline Preflushing Theoretical Scale

The ECMO Pipeline Preflushing Theoretical Scale has 58 items and consists of 3 parts: single-choice questions (40 items), multiple-choice questions (15 items), and short answers (3 items). The scale’s score ranges from 0 to 100.

ECMO Pipeline Preflushing Skills Scale

The ECMO Pipeline Preflushing Skills Scale has 61 items and consists of 3 parts: preparing items and materials according to the detailed list (13 item), preoperation preparation (5 items), and operation process (43 items). The scale’s score ranges from 0 to 100.

Data Analysis Tool

Based on the results of the pre-experimental study, the researchers referred to the average number of the ECMO pipeline preflushing needed to master the skill as 25 times. Therefore, this study counted the data of 30 operations used by each participant in the experimental group. Cumulative summation analysis (CUSUM) is a sequence analysis method first proposed by Page [17] to map the learning method of operation [18]. This study used CUSUM to draw the learning curve of the experimental group using a game-based mobile app to practice ECMO pipeline preflushing operation skills. The CUSUM was calculated as follows:

X_0 indicates the failure rate, and X_i represents the procedural success or failure of each practice. If it succeeds, then X_i=0, and if it fails, then X_i=1. In this study, we regarded the completion of the game before all the petals fell (within 9 mistakes) as a success, and the termination of the game as a result of all the petals falling was regarded as a failure. According to previous studies [19], the operation success rate was 94.4%, so the failure rate was X_0 = 1 – 94.4% = 5.6%.

The difference between the score of each operation of the participant and the set target value was sequentially accumulated. A learning curve was drawn, where the abscissa (*x* value) represents the number of intubation operations and the ordinate (*y* value) represents the sum of the previous cumulative sums. The curve fitting effect was evaluated by the curve fitting coefficient of determination (R^2), where $0 \le R^2 \le 1$. An R^2 value ≥0.95 indicates that the curve fit is satisfactory. The curve derivative function formula was obtained according to the curve function formula; the curve slope value corresponding to each operation was calculated; and the corresponding abscissa (*x* value) and the curve function value when the slope *k*=0 were calculated, that is, the curve peak value. The first integer value of *x* is the minimum number of operations the research participant needed to master the skill.

Data Analysis

The data obtained from the study were analyzed using the SPSS (version 24.0; IBM Corp) software package. The percentage, number, mean, and SD values were used in the descriptive statistical evaluation of the data. The normal or nonnormal distribution of the data was evaluated using the 1-sample Kolmogorov-Smirnov test. Nonparametric tests showed that the distribution of skill scores was nonnormal (*df*=86; *P*=.04). The skill scores between the 2 independent groups were compared using the Mann-Whitney *U* test. The χ^2 test was used to analyze the relation between the grouped variants. The Wilcoxon test was used in matching groups to determine the difference in scores between the first and final operation assessments and between the first and final skill performances. The data were evaluated at a *P*<.05 significance level.

Results

There was no significant difference in the distribution of descriptive characteristics between the control group and the experimental group (all *P*>.05; Table 1).

Table . Participant demographics between the control and experimental groups.

Demographics		Experimental group (n=43)	Control group (n=43)	*Z* score or χ^2 (*df*)	*P* value
Age (y), mean (SD)		30.51 (2.520)	30.44 (3.275)	−0.327[a]	.74
Number of working years, mean (SD)		6.93 (2.414)	6.84 (2.886)	−0.435[a]	.66
Sex, n (%)				0.231 (1)[b]	.63
	Female	32 (74)	30 (70)		
	Male	11 (26)	13 (30)		
Education, n (%)				0.311 (2)[b]	.86
	Postgraduate	4 (9)	5 (12)		
	Undergraduate	36 (84)	36 (84)		
	Junior college	3 (7)	2 (4)		
Job title, n (%)				3.817 (2)[b]	.15
	Senior	1 (2)	2 (4)		
	Intermediate	26 (60)	17 (40)		
	Junior	16 (38)	24 (56)		

[a]*Z* score.
[b]χ^2 value.

In the first ECMO pipeline preflushing theoretical test and skill operation test scores, no statistically significant differences were observed between the control group and the experimental group (*P*=.10 and *P*=.63). The experimental group's final theoretical test and skill operation test scores were significantly higher than those of the control group (*P*<.001). The final theoretical test and skill operation test scores of the experimental group were significantly higher than the first test scores of the experimental group (*P*<.001). The final theoretical test and skill operation test scores of the control group were also significantly higher than the first scores of the control group (*P*<.001; Tables 2 and 3).

Table . Difference in theoretical test scores between the control and experimental groups.

Score	Experimental group, median (range)	Control group, median (range)	*Z* score	*P* value
First theoretical test scores	75.88 (66-87)	74.42 (65-90)	−1.672	.10
Final theoretical test scores	88.44 (79-95)	85.02 (78-91)	−3.972	<.001[a]
Z score	−5.782	−5.715		
P value	<.001[b]	<.001[c]		

[a]Difference in theoretical test scores between the control and experimental groups at the final skill performance (*P*<.05).
[b]Difference in theoretical test scores between the first and final skill performance in the experimental group (*P*<.05).
[c]Difference in theoretical test scores between the first and final skill performance in the control group (*P*<.05).

Table . Difference in skill performance scores between the control and experimental groups.

Score	Experimental group, median (range)	Control group, median (range)	*Z* score	*P* value
First skill performance scores	75.44 (67-86)	75.93 (67-88)	−0.486	.63
Final skill performance scores	89.42 (82-94)	86.33 (76-94)	−4.145	<.001[a]
Z score	−5.783	−5.717		
P value	<.001[b]	<.001[c]		

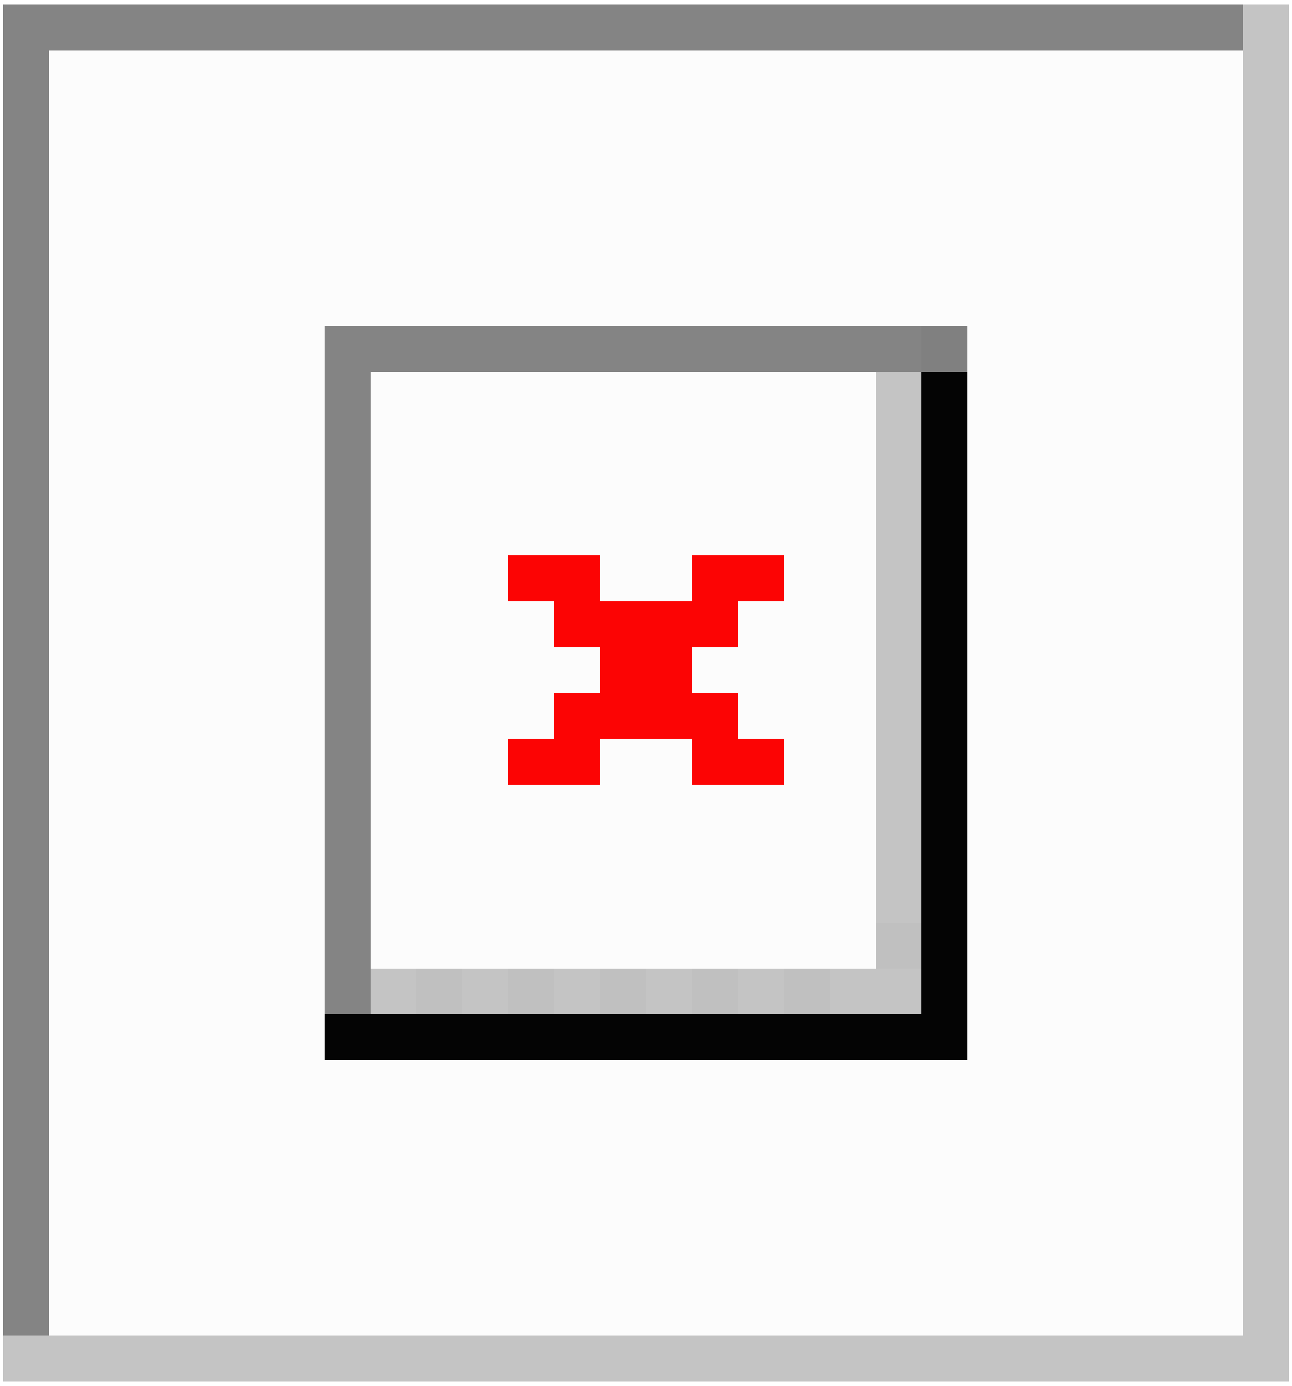
[a]Difference in skill test scores between the control and experimental groups at the final skill performance ($P<.05$).

[b]Difference in skill test scores between the first and final skill performance in the experimental group ($P<.05$).

[c]Difference in skill test scores between the first and final skill performance in the control group ($P<.05$).

The fitting curve model tests of the quadratic curve, compound function curve, exponential curve, and cubic curve showed that the *P* values were all <.05, and the R^2 values were 0.954, 0.498, 0.498, and 0.985, respectively. As $R^2>0.95$ for the quadratic curve and the cubic curve, the best fitting model curve was the cubic curve (Figure 5), and the fitting equation was $\sum i(\text{CUSUM value}) = 0.04x^3 - 3.17x^2 + 71.99x - 61.83$ (x=the number of operations). When the slope of the curve is 0, the corresponding abscissa (*x* value) represents the average number of operations for the group of students to master this skill. Calculated by the curve function formula, the first integer value of *x* after the peak of the curve of the experimental group was 17. Therefore, the minimum number of operations required for the experimental group to master this skill was 17.

Figure 5. The average learning curve of the experimental group. CUSUM: cumulative summation analysis.



Discussion

Principal Findings

In this study, the final averages of the ECMO pipeline preflushing theory and skill scores of the control group and the experimental group increased. The final theory and skill performance scores of the experimental group were significantly higher than those of the control group (*P*<.001). Both the game-based mobile app simulation training method and the conventional training method improved the theoretical knowledge and skill level of intensive critical care specialist nurses, but the game-based mobile app simulation training method was more effective than the conventional training method, which was consistent with the results of Gu et al [20]. In addition, the study used learning curve analysis to find that the experimental group of nurses needed 17 operations to master this skill.

Learning curves are increasingly used for health care education and formative assessment [21,22]. Every operation in the medical field requires a process from being unfamiliar to skilled. By establishing an operational learning curve, students' mastery can be assessed [23]. It could be seen from the learning curve that in the initial stage of learning, the curve showed an upward trend and the growth rate was large. This might be because at this stage, the participants were not familiar with the operation process and the rules of the game, and the researchers set the number of mistakes to only 9 in the game. Once the number of mistakes was too high, the game was terminated. In this period, the number of successful completions of the game was relatively small, so the CUSUM value increased greatly. After the first stage of grouping and learning, as participants became familiar with the operating process, although the learning curve continued to rise, the growth rate began to decrease. We called this period the plateau period. During this period, the slope of the curve was still positive but gradually approached 0. When the learning curve began to show a downward trend, the slope of the curve began to be negative, indicating that the number of successful players in the game was gradually increasing. The reason for these results might be that after studying and gaining experience, the participants were very familiar with the operation process of ECMO pipeline preflushing and could complete the game according to the correct steps within the specified number of 9 mistakes. Therefore, the learning curve analysis showed that the nurses in the experimental group needed 17 operations to master the skill.

Contributions and Implications

Game-based mobile apps can simulate real-life situations, and nurses or students can enter the clinical situation from the virtual world and improve practical skills and confidence before actual operations [24]. The results of this study were similar to the results of Bayram and Caliskan [25], which showed that the average score of nursing skills for pneumatic tube ostomy after using the game-based virtual reality application method was significantly improved. This app is suitable for Windows, Android, Mac, and other platforms and can be installed on computers, mobile phones, tablets, etc, thus achieving platform and network diversity. Most importantly, the game-based app provides participants with the opportunity and environment to practice and test learning outcomes anytime, anywhere, and with an unlimited number of attempts. This is different from traditional operation practices, where there is limited space, only a small number of participants can practice at a time, and the practice room is only open for a short time, along with other complicating factors. Overall, the integration of game-based mobile apps into ECMO pipeline preflushing education in China is effective in improving the learning time, knowledge, and skill level of intensive critical care specialist nurses compared to traditional training methods.

Significance for Clinical Education

This study confirms that a game-based mobile app can help intensive critical care specialist nurses better learn and master ECMO pipeline preflushing skills. The app can help nurses translate the theoretical knowledge of nursing into practice, stimulate learners' interest in learning, optimize the learning process, improve the learning effect, and cultivate clinical critical thinking. This app enables intensive critical care specialist nurses to learn the correct ECMO pipeline preflushing procedure for error-free operation in future clinical work while being a tool for nurses to learn and test learning outcomes anytime and anywhere. In addition, by establishing a learning curve, we understood how nurses learn a certain clinical operation for the first time and the amount of operational training required to master this operation, which has guiding significance for the development of clinical skills.

Limitations

First, in the early stages of learning, both groups of nurses made mistakes, leading to failure, but we could not identify which steps had a high error rate. Therefore, we could not explain the reason for the high failure rate of the early operations. Second, we could not monitor the scores of the nurses in the control group during each operation practice. Therefore, we could not draw the learning curve of the control group at this time, and there was no way to compare the learning curves of the 2 groups. Third, we will use more comprehensive sampling and randomized controlled trials in future investigations. According to the follow-up feedback of the research participants, we will add related knowledge questions, related knowledge teaching videos, and scene simulation modules in the follow-up study to improve the mobile app and its attractiveness and effectiveness.

Conclusions

This study suggests that a game-based mobile app may be more effective for intensive critical care specialist nurses in ECMO pipeline preflushing education than traditional Chinese lecture-practice education. In addition, the ECMO pipeline preflushing skill can be mastered by playing the game 17 times.

Acknowledgments

The authors thank Professor Lin De Jun for his assistance in developing the game-based mobile app. In addition, the authors would like to acknowledge all nurses and the training management teams in this study for their contributions. This work was supported by the Department of Humanities and Social Sciences, Qingdao University, China (grant RZ2100005016); the 2021 Qingdao Medical and Health Research Program Project (grant 2021-WJZD181); and the 2020 Teaching Research and Reform Project of Qingdao University School of Medicine and Qingdao Outstanding Health Professional Development Fund.

Abstract

Background: Positive self-esteem predicts happiness and well-being and serves as a protective factor for favorable mental health. Scholarly gaming within the school setting may serve as a channel to deliver a mental health curriculum designed to improve self-esteem.

Objective: This study aims to evaluate the impact of a scholarly gaming curriculum with and without an embedded preventive mental health curriculum, Mental Health Moments (MHM), on adolescents' self-esteem.

Methods: The scholarly gaming curriculum and MHM were developed by 3 educators and a school-based health intervention expert. The scholarly gaming curriculum aligned with academic guidelines from the International Society for Technology Education, teaching technology-based career skills and video game business development. The curriculum consisted of 40 lessons, delivered over 14 weeks for a minimum of 120 minutes per week. A total of 83 schools with previous gaming engagement were invited to participate and 34 agreed. Schools were allocated to +MHM or –MHM arms through a matched pairs experimental design. The –MHM group received the scholarly gaming curriculum alone, whereas the +MHM group received the scholarly gaming curriculum plus MHM embedded into 27 lessons. MHM integrated concepts from the PERMA framework in positive psychology as well as the Collaborative for Academic, Social, and Emotional Learning (CASEL) standards in education, which emphasize self-awareness, self-management, social awareness, relationship skills, and responsible decision-making. Participants in the study were students at schools offering scholarly gaming curricula and were enrolled at recruitment sites. Participants completed a baseline and postintervention survey quantifying self-esteem with the Rosenberg Self-Esteem Scale (score range 0-30). A score <15 characterizes low self-esteem. Participants who completed both baseline and postintervention surveys were included in the analysis.

Results: Of the 471 participants included in the analysis, 235 received the –MHM intervention, and 236 received the +MHM intervention. Around 74.9% (n=353) of participants were in high school, and most (n=429, 91.1%) reported this was their first year participating in scholarly gaming. Most participants were male (n=387, 82.2%). Only 58% (n=273) reported their race as White. The average self-esteem score at baseline was 17.9 (SD 5.1). Low self-esteem was reported in 22.1% (n=104) of participants. About 57.7% (n=60) of participants with low self-esteem at baseline rated themselves within the average level of self-esteem post intervention. When looking at the two groups, self-esteem scores improved by 8.3% among the +MHM group compared to no change among the –MHM group (P=.002). Subgroup analyses revealed that improvements in self-esteem attributed to the +MHM intervention differed by race, gender, and sexual orientation.

Conclusions: Adolescents enrolled in a scholarly gaming curriculum with +MHM had improved self-esteem, shifting some participants from abnormally low self-esteem scores into normal ranges. Adolescent advocates, including health care providers, need to be aware of nontraditional educational instruction to improve students' well-being.

Introduction

Self-esteem is an important marker of overall adolescent well-being. Positive self-esteem predicts happiness, academic performance, and resiliency among other favorable outcomes, whereas low self-esteem contributes to anxiety and depression [1,2]. Because self-esteem can be either a risk factor or a protective factor for mental health challenges, it is critically important to target with supportive initiatives.

Adolescence is a pivotal time to develop positive self-esteem. A strong sense of self-worth propels adolescents to explore new opportunities and may help navigate feelings of inadequacy when experiencing common challenges at this age, such as friend group transitions, feelings of awkwardness, and unexpected emotional lability [3]. The benefits of self-esteem have been especially relevant since 2000 when the prevalence of anxiety, depression, and suicidal ideations began to increase in adolescents, worsening during the COVID-19 pandemic, and remaining slow to improve despite the end of COVID-19 restrictions [4-7].

One cohort of adolescents, high-volume technology users, are at increased risk for low self-esteem [8-10]. Multiple hypotheses exist for this relationship, including comparing self to social media standards and the social isolation that can occur with excessive video gaming [11,12]. In contrast, several research inquiries suggest that interactive technology use can be helpful [13,14]. One primary reason is that technology can serve as a motivator for behavioral intervention and contribute to the promotion or reduction of certain behaviors [15]. For example, in the educational space, interactive websites and captivating software apps can ignite student engagement, improve academic performance, and serve as a reward for completed learning objectives [16].

A more extensive example of using technology to positively shape behavior is scholarly gaming. Scholarly gaming is an academic course in secondary schools that leverages student excitement around video gaming to teach technology-based career skills, project-driven teamwork, and accountability for adolescents. However, there appears to be a gap that scholarly gaming has yet to fill—supporting the self-esteem of student participants. Many of the students who enroll in scholarly gaming classes may not be well connected to school life outside of their interest in technology and gaming, putting them at risk for feelings of isolation [17].

Our intervention offered a scholarly gaming curriculum that embedded opportunities to develop positive self-esteem within the academic instruction, serving as a vessel to deliver a mental health curriculum; offered schools an opportunity to improve the emotional well-being of adolescents at baseline; and promoted an inclusive extracurricular activity for interested students, boosting feelings of self-worth and confidence [18]. With these design elements, scholarly gaming could offer a practical and affordable approach to student mental health support, which many experts in education desire [19,20].

The purpose of this study is to evaluate the impact of scholarly gaming with and without an embedded mental health curriculum, known as Mental Health Moments (MHM), on the self-esteem of adolescents. We hypothesized that students participating in a scholarly gaming curriculum with embedded MHM (+MHM) would show greater improvement in self-esteem compared to the same scholarly gaming curriculum without the MHM (−MHM). To evaluate the hypothesis, we quantitatively assessed the self-esteem of adolescents at baseline and post intervention (+MHM or –MHM).

Methods

This prospective study compared baseline and postintervention self-reported self-esteem scores from adolescents participating in +MHM and –MHM. This study occurred from December 2021 through May 2022.

Setting and Participants

Recruitment for this study occurred at secondary schools in Canada and the United States. Eligible schools were identified by reviewing prior enrollment in school-sponsored gaming events, demonstrating that the school had the tech resources to support a scholarly gaming course. All schools that had participated in school-sponsored gaming events (N=83 middle and high schools in North America) were invited via email to participate in the study. A total of 34 schools agreed to participate, representing more than 30 independent districts across the United States (11 states) and Canada (1 province). There was no statistical difference between the schools that enrolled versus those that declined when comparing student body size, public versus private, Title 1 status, and poverty rates (Multimedia Appendix 1). There was a slight geographic difference between schools who agreed and declined to participate, with schools in the Midwest (55%) and West (55%) being more likely to enroll than schools in the Southwest (33%), Northeast (20%), or Southeast (7%; $P<.001$; Table S1 in Multimedia Appendix 1).

The most common reason for declining enrollment in the study was faculty preference, as some teachers did not want to deviate from pre-existing lesson plans. A total of 17 schools each were allocated to the intervention (+MHM) and control (–MHM) arms.

Participant eligibility included enrollment in a course that provided the –MHM or +MHM scholarly gaming curriculum at a participating school, aged 12-18 years, and a class schedule that allowed engagement with the study-approved curriculum for 120 minutes each week. No student was required to participate, and students could withdraw at any time from the survey process. There was no compensation or benefits in kind for participation.

Ethical Considerations

Participating schools considered their local legislation and institutional requirements before joining the study. Additionally, scholarly gaming teachers provided all eligible participants with a written informed assent/consent form to share with their guardians. The institutional review board at Children's Mercy Hospital and Clinics (Kansas City, MO) approved the secondary analysis of data (STUDY00002344) collected by the study investigators who designed the +MHM and −MHM programs.

Study Design and Allocation

In this prospective study, participating schools were allocated to +MHM and –MHM arms through a matched pairs experimental design, balancing the number of students enrolled in the school, Title 1 status, public versus private, and geography.

Interventions

Teacher Training

All teachers received the following resources at no cost: access to either the +MHM or −MHM curriculum guides on the web, depending on their study allocation; paper versions of the curriculum guides as a backup; student handouts for applicable lessons; and three video tutorials. The curriculum guides included scripted lessons, along with standardized presentation materials and supplements for each lesson. The video tutorials explained how to use the scholarly gaming curriculum consistently and follow the data collection process, and emphasized the need for a standardized experience throughout the study. Finally, teachers were informed that the study sought to measure the impact of a new curriculum on self-esteem over time but were blinded as to whether they were providing +MHM or –MHM.

Standard Curriculum (–MHM)

The scholastic gaming curriculum included 40 lessons over 14 weeks for a minimum of 120 minutes per week. The goal of the curriculum was to teach students meaningful skills and knowledge needed to work in the digital gaming industry. Examples include project management, graphic design, basic coding, marketing, maximizing team performance, and career opportunities linked to gaming. The curriculum, designed by multiple educators and a school-based health intervention expert, was organized into units, daily lessons, and timed projects. The –MHM curriculum content aligned with the International Society for Technology in Education (ISTE) benchmarks. Lessons were led by the teacher and provided a standardized experience through prewritten lesson plans (within the curriculum) for teachers to follow. Each lesson plan engaged study participants with prescriptive teacher dialogue and premade resources (eg, worksheet or infographic) created by the curriculum writers. The research team verified with the participating schools that the scholastic gaming teacher held the appropriate professional licensure and certification to teach secondary school in that state/province.

Standard Curriculum With Embedded Mental Health Moments (+MHM)

Participants allocated to the +MHM group received the same scholastic gaming curriculum and teacher training as those in the –MHM group but with the addition of +MHM embedded into 27 of the 40 scholarly gaming curriculum lessons. To make room for the embedded +MHM, 10 minutes of student work time was removed from the lesson plan. There were no other changes made. +MHM was designed by the same team of professionals as –MHM and aligned with the previously mentioned ISTE standards and validated frameworks in education and psychology that support favorable mental health [21,22]. Additionally, all scholarly gaming teachers who provided +MHM met the same credentialing standards as the –MHM faculty.

The primary goal of +MHM was to promote positive self-esteem in participants, growing confidence in their worth and abilities. +MHM accomplished this goal by linking elements of the tech-based academic lesson to one of three premade student experiences (discussion, activity, or personal reflection) that provided insight into one or more of the following: self-awareness, self-management, social awareness, relationship skills, responsible decision-making, positive emotions, engagement, sense of meaning, and achievements. All +MHM experiences were led by the teacher in a standardized way, using prescriptive teacher dialogue and premade resources from the curriculum. +MHM experiences were designed to be delivered in 10 minutes, as this was the time allotment created for them.

To illustrate an example of +MHM, an academic lesson that explored harsh feedback for a game design linked itself to a discussion regarding the "purpose of emotions" and offered scripted strategies for controlling emotions calmly and professionally. An expanded example of an MHM lesson can be found in Multimedia Appendix 2.

Measures

At baseline and post intervention (14 weeks), each school's scholastic gaming teacher was emailed a link to the electronic study surveys. Upon receipt of the link, teachers distributed the surveys to each student enrolled in the study to complete within a standardized window of 5 days. All survey responses were deidentified through a school code plus a number that was selected by each student. Supervising teachers were directed to ensure no duplicate student numbers.

Demographic Characteristics

Students were asked to report their age; grade in school; number of years participating in scholastic gaming; race; gender; and if they identified as lesbian, gay, bisexual, transgender, queer (LGBTQ+). Grade in school was categorized into middle (grades 6 through 8) or high school (grades 9 through 12). Years of participation in scholastic gaming was categorized as "first year" versus "two or more years." Race was asked by "Which do you identify with?" allowing participants to select one or more options. Race was classified as American Indian or Alaska Native, Asian, Black or African American, Hispanic or Latino, Native Hawaiian/Pacific Islander, White, more than one race, or prefer not to say or unknown. Gender was asked similarly to race, allowing participants to select male, female, or nonbinary. Students could also identify as LGBTQ+ or not LGBTQ+.

Self-Esteem

The Rosenberg Self-Esteem Scale (RSES), a validated scale consisting of 10 questions on a four-point Likert scale measured participant self-esteem at baseline and week 14 [23]. The total RSES score was calculated by summing responses to each question and reverse coding five questions that use negative phrases. Scores range from 0 to 30, with lower scores indicating lower levels of self-esteem. A score of less than 15 is considered low self-esteem [23,24]. A binary variable indicating if a student had low self-esteem (defined as RSES <15) was created.

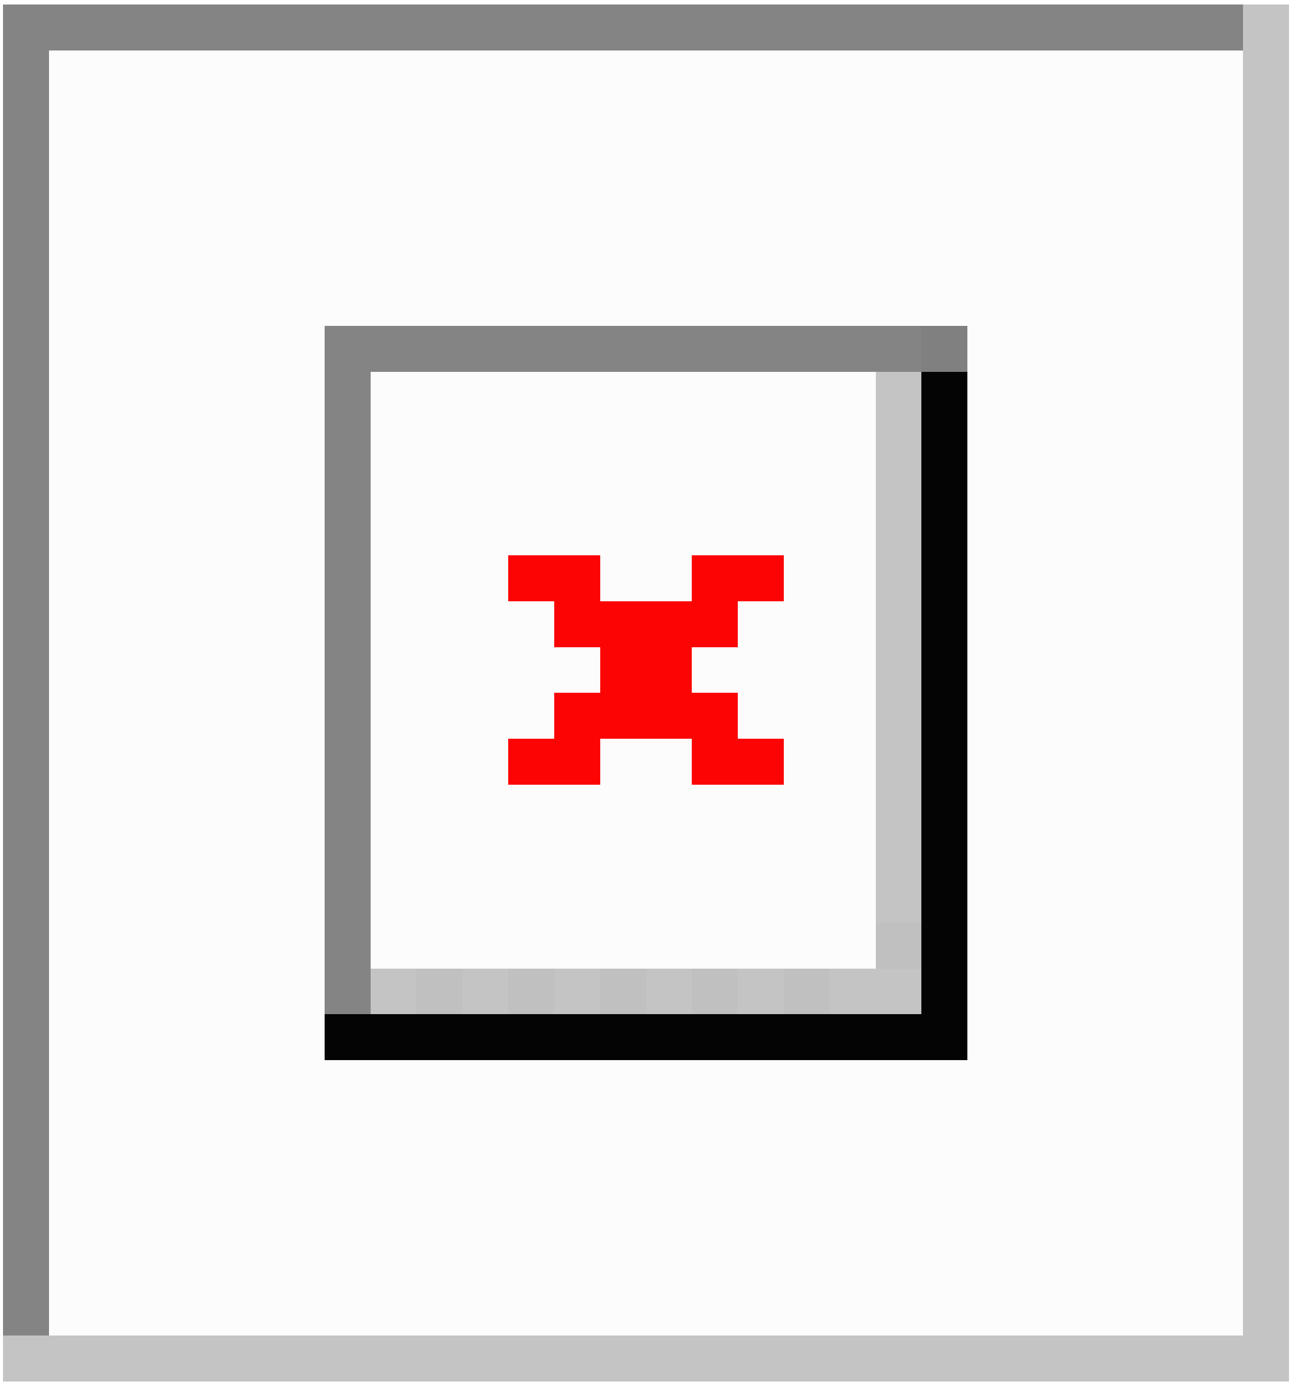
Data Analysis

Basic descriptive statistics (frequencies, means) were used to describe the study sample. Baseline demographic differences between the +MHM and –MHM groups were assessed using χ^2/Fisher exact and *t* tests for categorical and continuous data, respectively. Changes in the RSES score from baseline to postintervention as a continuous variable were assessed via multivariable repeated measures linear regression, controlling for baseline imbalances between the study arms. A multilevel model was implemented to account for the clustering of individuals within each school. Subgroup analyses were conducted using multivariable repeated measures linear regression to examine if there was a differential impact on the MHM curriculum by race, gender, and sexual orientation. Subgroup analyses collapsed the following racial categories into an "additional races" category due to small sample sizes: American Indian and Alaska Native, Asian, Native Hawaiian or Pacific Islander, more than one race, or prefer not to say or unknown. Students who chose not to self-report their gender were excluded from the subgroup analyses related to gender. The association between the MHM curriculum and improvement of low self-esteem (RSES score <15) was assessed using multivariable logistic regression controlling for baseline imbalances between the study groups. All analyses were completed using SAS Version 9.4 (SAS Institute, Inc).

Results

Among the 34 participating schools, 710 students enrolled in the study. Of those, 471 students completed all surveys (+MHM: n=236; –MHM: n=235) and were included in the analyses (Figure 1).

Figure 1. Study participation.



Demographic Characteristics

The majority (n=353, 74.9%) of the 471 participants were enrolled in grades 9-12 at the time of the study, were male (n=387, 82.2%), and reported that this was their first year participating in scholastic gaming (n=429, 91.1%). About half (n=273, 58%) reported their race as White. The characteristics of students in each study group were balanced at baseline, except for age and race. The mean age of students in the +MHM arm was slightly less than that of the –MHM arm (14.9, SD 1.5 years vs 15.2, SD 1.8 years; *P*=.04). The distribution of self-reported race was even between the study groups, except for the +MHM group that included more students who reported their race as Asian than the –MHM group (19/236, 8.1% vs 9/235, 3.8%), and the +MHM group also had fewer students who reported their race as White than the –MHM group (125/236, 53% vs 148/235, 63%; Table 1).

Table . Baseline characteristics of study participants.

Characteristic		Total (n=471)	+MHM[a] (n=236)	–MHM (n=235)	*P* value[b]
Years of participation, n (%)					.99
	First year	429 (91.1)	215 (91.1)	214 (91.1)	
	Two or more years	42 (8.9)	21 (8.9)	21 (8.9)	
Grade level, n (%)					.38
	Middle school	118 (25.1)	55 (23.3)	63 (26.8)	
	High school	353 (75.0)	181 (76.7)	172 (73.2)

[a]MHM: Mental Health Moments.

[b]*P* value from χ^2 or *t* test.

[c]Italics indicate statistically significant differences between study groups at baseline.

[d]Fisher exact test.

[e]LGBTQ+: lesbian, gay, bisexual, transgender, queer.

[f]Rosenberg Self-Esteem Scale scores range from 0 to 30, with lower scores indicating lower levels of self-esteem.

[g]A Rosenberg Self-Esteem Scale score <15 indicates low self-esteem.

There were statistically significant differences in the study group, race, and gender identification between those who were included in the analyses versus those excluded due to not completing the follow-up assessment. Students enrolled in the +MHM group were more likely to be included in the analyses than those in the –MHM group, students who declined to report their race at baseline and those who reported their race as Black or African American were less likely to be included than other races, and students reporting their gender identity as male or nonbinary were more likely to be included than those who reported their gender as female or declined to report (Multimedia Appendix 3).

Self-Esteem

Baseline

The mean RSES score among the entire study sample at baseline was 17.9 (SD 5.1), with 22.1% (104/471) falling into the low self-esteem category (RSES <15). +MHM and –MHM had similar mean self-esteem scores at baseline (18.0, SD 5.4 and 17.9, SD 4.9, respectively; *P*=.80), with 52 participants in each group having low self-esteem (Table 1).

Postintervention –MHM

Among –MHM participants who had low self-esteem at baseline (RSES <15), 54% (28/52) had self-esteem scores in the normal range (15 or greater) by the end of the study (Table 2). RSES as a continuous variable did not change over time in the –MHM group (baseline RSES 17.9, SD 4.9; postintervention RSES 17.9, SD 5.5; Table 3). Self-esteem scores increased slightly among –MHM students reporting their race as White, Hispanic/Latino, and the races collapsed into the additional races category. Among –MHM students reporting their race as Black or African American, self-esteem decreased from baseline to the end of the study. Self-esteem scores also decreased among –MHM students reporting their gender as male, female, and nonbinary (Table 4).

Table . Odds of low self-esteem improving to normal by the end of the study period. Results of logistic regression controlling for age and race. The analysis includes 104 students with Rosenberg Self-Esteem Scale score <15 at baseline.

	Low self-esteem[a] improved[b], n (%)		aOR[c] (95% CI)
	Yes (n=60)	No (n=44)	
+MHM[d] (n=52)	32 (61.5)	20 (38.5)	1.17 (0.68-2.01)
–MHM (n=52; reference)	28 (53.9)	24 (46.2)	1.0

[a]Abnormally low self-esteem defined as Rosenberg Self-Esteem Scale score <15.

[b]Improvement measured as a score ≥15 by the end of the study.

[c]aOR: adjusted odds ratio.

[d]MHM: Mental Health Moments.

Table . Changes in self-esteem scores over time. Results of repeated measures linear regression controlling for age and race.

		Rosenberg Self-Esteem Scale score[a], mean (SD)[b]		*P* values[c]		
		Baseline	Week 14	Group[d]	Time[e]	Group × time[f]
Study group				.14	*<.001* [g]	*.002*
	+MHM[h]	18.0 (5.4)	19.5 (5.6)			
	−MHM	17.9 (4.9)	17.9 (5.5)			

[a]Rosenberg Self-Esteem Scale scores range from 0 to 30, with lower scores indicating lower levels of self-esteem.

[b]Raw means for respondents at each time point.

[c]*P* values are based on model-based means for repeated measure analyses controlling for age.

[d]*P* value group: differences in self-esteem scores at baseline between study groups.

[e]*P* value time: differences in self-esteem scores between baseline and week 14.

[f]*P* value group × time: differences in change in self-esteem score over time by study group.

[g]Italics indicate statistically significant results.

[h]MHM: Mental Health Moments.

Table . Subgroup analyses of changes in Rosenberg Self-Esteem Scale scores over time by race, gender, and sexual orientation. Results of repeated measures linear regression controlling for age and race.

[a]Rosenberg Self-Esteem Scale scores range from 0 to 30, with lower scores indicating lower levels of self-esteem.

[b]Displays raw means for actual respondents at each time point.

[c]*P* values are based on model-based means for repeated measure analyses controlling for age.

[d]*P* value group: differences in self-esteem scores at baseline between study groups.

[e]*P* value time: differences in self-esteem scores between baseline and week 14.

[f]*P* value group × time: differences in change in self-esteem score over time by study group.

[g]Race subgroup analyses did not control for race.

[h]Italics indicate statistically significant results.

[i]MHM: Mental Health Moments.

[j]Additional races collapsed due to small sample sizes. Includes American Indian or Alaska Native, Asian, Native Hawaiian or Pacific Islander, more than one race, and prefer not to say/unknown.

[k]Four students who did not wish to disclose their gender were excluded from these analyses.

[l]LGBTQ+: lesbian, gay, bisexual, transgender, queer.

Postintervention +MHM

Among +MHM students who had low self-esteem at baseline (RSES <15), 62% (32/52) had self-esteem scores in the normal range (15 or greater) by the end of the study (Table 2). Self-esteem improved by about 8.3 percentage points from baseline to postintervention for the +MHM group (baseline RSES mean 18.0, SD 5.4; postintervention RSES mean 19.5, SD 5.6; Table 3). Among racial subgroups, self-esteem improved among +MHM students reporting their race as Black or African American, Hispanic/Latino, and White. Self-esteem decreased slightly among those falling into the additional races category. Results also displayed improvements in self-esteem among +MHM students reporting their gender as female and nonbinary. The largest improvement in self-esteem was among the LGBTQ+ subgroup, whose mean RSES score improved from 13.5 (SD 4.7) at baseline to 18.8 (SD 6.4) by the end of the study (Table 4).

Postintervention –MHM Versus +MHM

Results from the multilevel multivariable linear regression found that mean RSES score improvement over time was greater among the +MHM group (baseline: 18.0, SD 5.4; week 14: 19.5, SD 5.6) compared to the –MHM group (baseline: 17.9, SD 4.9; week 14: 17.9, SD 5.5; group × time; P=.002; Table 3). Additional subgroup analyses found that the +MHM intervention improved self-esteem more than the –MHM intervention among students identifying as African American or Black, White, male, female, and non-LGBTQ+ (see P values for group × time in Table 4).

Results of the multivariable logistic regression found that, among students with low self-esteem at baseline, the odds of reaching normal levels of self-esteem by week 14 were greater among students who were enrolled in +MHM compared to those in the –MHM group (adjusted odds ratio 1.17, 95% CI 0.68-2.01), although this finding was not statistically significant (Table 2).

Discussion

Principal Results

Our study found that the scholarly gaming curriculum produced a clinically relevant migration of participants from abnormally low self-esteem baselines to a normal range, and the +MHM group had greater self-esteem score improvement than the –MHM group. This suggests that the insertion of embedded preventive mental health (+MHM) into the scholarly gaming curriculum may amplify the well-being benefit of the scholarly gaming curriculum. Furthermore, the large sample size over one semester suggests delivering an embedded mental health curriculum within an academic course is feasible.

Independent of the macroscopic changes that embedded preventive mental health might offer, it's equally important to discuss the impact this intervention made on higher-risk cohorts of adolescents, as mental health burdens are not carried equally.

Implications for Adolescents at Higher Risk for Mental Health Threats

The Centers for Disease Control and Prevention reports that females; students of color; and individuals who identify as lesbian, gay, or bisexual are often at higher risk for mental health challenges throughout adolescence [25,26]. Subgroup analyses within our study revealed differences in the impact of the scholarly gaming curriculum (with or without MHM) between races, genders, and LGBTQ+ identification. These changes were magnified in the +MHM group, suggesting that embedded preventive mental health might offer some valuable improvements in self-esteem for several of the CDC-defined "higher risk" cohorts.

Female Adolescents

Participants who identified as female and received +MHM experienced an increased trend in self-esteem from baseline to the end of the study when compared to those who identified as female and received –MHM. This positive impact linked to embedded preventive mental health (+MHM) is worth noting for adolescent advocates—something they might consider sharing with schools in their community, given that adolescent females displayed a 53% increase in emergency department visits for suicidal ideations in 2021 compared to 2019 [27].

Students of Color

Racism can serve as a structural and social determinant of health that increases stress and negatively impacts mental health, making protective factors for mental health critically important to minoritized cohorts [28,29]. It is worth noting that Black and Hispanic/Latino participants who engaged with +MHM demonstrated increases in perceived self-esteem when compared to baseline values and the –MHM cohort for their race. It is possible that a curriculum that emphasizes student self-worth and provides an opportunity for peer connection as much as academic content may be beneficial for people of minoritized groups.

LGBTQ+ Identification

Adolescents who identify as LGBTQ+ sometimes have trouble finding a supportive niche and friend groups in school [30]. This can be a detriment to mental health, as prior research demonstrates how inclusion in extracurricular activities boosts students' perceptions of self-worth and confidence [31]. Enter scholarly gaming, an activity with no historical precedents and a nonthreatening environment for LGBTQ+ students potentially seeking a sense of belonging and friendship. The results demonstrated an increase in self-esteem scores for all LGBTQ+ participants post intervention. Furthermore, although not statistically significant due to sample size, students in the +MHM group who identified as LGBTQ+ had the lowest self-esteem scores at baseline and saw the largest improvement in self-esteem by the end of the study when compared to all other cohorts in the study. These findings may be related to benefits provided by the inclusive design of scholastic gaming and the impact of +MHM, suggesting that other school activities with a similar inclusive nature and embedded preventive mental health may benefit students who identify as LGBTQ+.

Comparison With Prior Work

To the best of our knowledge, this study is one of the first to quantify the impact of embedded preventive mental health within standard curricula, as compared to traditional social-emotional learning, which is often taught independent of academic content. Equally important, this study made a deliberate choice to use scholarly gaming, a class arguably centered around technology and video gaming, as the conduit to +MHM. The intent was to demonstrate that if +MHM could offer benefits in a scholarly gaming curriculum, it might offer benefits in another academic curriculum. Future implementations of the +MHM curriculum will need to be scalable for non–scholarly gaming classes, perhaps through universal instructional strategies, to see if they offer benefits for participants.

Limitations

The strengths of this study include its use of a longitudinal design, large sample size, and an intervention that was practical and affordable for schools to implement. Nevertheless, several limitations of this study should be considered. First, although the curriculum was prescriptive and standardized, we could not guarantee implementation validity, even with teacher training. Second, although the attrition rate was similar between both the +MHM and –MHM study groups, we could not definitively determine the causes of participant dropout. Third, the allocation of schools to the +MHM and –MHM groups used a matched pairs experimental design with the following key variables: student number, school number, Title 1 status, public versus private, and geographic distribution. While the nonrandom allocation pattern has the potential to introduce bias, we accounted for this by controlling for imbalances between the study groups at baseline and using multilevel modeling. Additionally, the LGBTQ+ categorization in our study was only able to classify a student as identifying as LGBTQ+ or not; we were unable to determine specific gender identities or sexual orientation. Further studies should consider more detailed identification. Finally, these findings may not be generalizable beyond students participating in a scholarly gaming curriculum. Future studies should evaluate the impact of the integration of +MHM into other curricula on student self-esteem.

Conclusions

Scholarly gaming with +MHM, a tech-based course that seems to capture the interest of many students, might serve as a successful conduit for embedded preventive mental health curriculum, improving the self-esteem of participants. This is particularly relevant, as scholarly gaming curricula often reach some of the most vulnerable youth through school-based interventions. Furthermore, if an embedded preventive mental health curriculum offers benefits in a scholarly gaming course, it might offer benefits in other academic settings [32,33]. Adolescent advocates and researchers should be aware of this potential opportunity for rapidly expanding school-based interventions to support self-esteem.

Acknowledgments

We would like to extend our appreciation to all the dedicated educators who implemented this curriculum across the United States and Canada. Thank you to Ryan Thomas, MD, at the University of Florida Health System and Mary Hamm, MD, at Leawood Pediatrics for providing an impactful peer review before manuscript submission. Generative artificial intelligence was not used for any part of this manuscript. Funding was provided by Generation Esports (no grant number) to manufacture the +MHM (Mental Health Moments) and –MHM curriculum. The funder was not involved in the study design, data collection, analyses, interpretation of the data, or manuscript submission.

Data Availability

The data sets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

CJ led the conceptualization, investigation, resources, and supervision, and helped design the data curation. SFW generated all formal analyses and methodology. LMM led the reviewing and editing. Validation, visualization, and writing the original draft were shared equally by all three authors.

Conflicts of Interest

CJ was compensated for cowriting the scholarly gaming curriculum with +MHM.

Abstract

Background: Virtual learning environments (VLEs) use a virtual environment to support learning activities. VLEs are commonly used to overcome the temporal and spatial restrictions of learning activities held in conventional face-to-face classrooms. In VLEs, students can participate in learning activities using the internet, and teachers can provide assistive learning tools during the process.

Objective: The purpose of this study was to investigate the relationships among nursing students' mental load, cognitive load, and affective learning outcomes in terms of their willingness to serve older adults in an interaction-based educational virtual reality (VR) learning environment.

Methods: This study used a cross-sectional method. A total of 130 students participated in interaction-based VR learning and completed related questionnaires. Descriptive and inferential statistics and stepwise regression for data analysis were used.

Results: The research results revealed that in the dimension of willingness to use VR learning materials, perceived usefulness received the highest score (mean 4.42, SD 0.45). In the dimension of nursing ability, students scored the highest in information management and application ability to care for case patients (mean 4.35, SD 0.54). Correlation analysis revealed that cognitive load during learning and willingness to serve older adults were negatively correlated, whereas willingness to use VR learning materials was positively correlated with nursing ability and willingness to serve older adults. Analyzing the regression coefficients of predictor variables revealed that willingness to use VR learning materials (β=.23; t_2=2.89, *P*=.005) and cognitive load during learning (β=–.35; t_2=–.4.30, *P*<.001) were predictive factors of nursing students' willingness to serve older adults.

Conclusions: This study demonstrated that students' willingness to use VR learning materials and their cognitive load during learning affected their willingness to care for older adults. Therefore, the components of mental or cognitive load generate inconsistent predictive effects on affective variables and willingness to serve older adults.

Introduction

As a consequence of population aging in many countries, nurses must be equipped with the ability to care for older adults, perform early assessments, and establish care demands. In nurse cultivation and education, technology learning elements are incorporated. Virtual learning environments (VLEs) use a virtual environment to support learning activities. VLEs are commonly used to overcome the temporal and spatial restrictions of learning activities held in conventional face-to-face classrooms. VLEs are learning environments free from temporal and spatial constraints that use a web-based virtual space to ensure representational fidelity and facilitate learner interactions. VLEs are typically established on servers.

In a VLE scenario, learners can perceive a construction of identity and a sense of presence and copresence. VLEs provide learners with multimedia materials and can be paired with teaching strategies. According to teaching goals, models can be designed to provide learning activities that assist learners in completing learning tasks [1,2]. VLEs have the following characteristics. (1) VLEs are planned information spaces. (2) VLEs are social spaces in which teachers and students can interact through teaching and learning processes. (3) Information and social spaces can be presented using text and 2D or 3D virtual reality (VR) modes. (4) In a VLE, students can participate in learning activities and discuss the content of the virtual learning space with teachers. (5) VLEs can integrate various techniques and teaching methods to innovate teaching. (6) VLEs can be used in distance teaching or in reinforcing classroom-based learning activities [1-5].

With advancing technology, content that cannot be presented using conventional teaching methods has gradually been converted using VR capabilities to enhance student learning. VR offer students the virtual experience of being in an actual environment and is suitable for assisting learning for scholars, students, nursing personnel, and patients [6]. In VLEs, students can participate in learning activities using the internet. During the process, teachers can provide assistive learning tools, such as web-based exchange and discussion, web-based tests, uploaded files, assignment submission, peer discussion, peer assessment, grading, questionnaires, and learning-history tracking, thereby generating rich interactive learning experiences [1,2,7].

Hodgson et al [8] used interactive VR lesson plans to support discussion and teaching, discovering that 65% of study participants reported that using VR for case discussion could increase their learning interests and assist them in preparing for future clinical internship scenarios. For the field of nursing, Chiou et al [9] established a VR learning platform to simulate the clinical scenario medication administration. They stated that students exhibited interest in the learning process and improved self-learning efficacy. Ball [10] applied the VR 360 Photosphere environmental platform experimentally, determining its ability to reduce students' anxiety about actual clinical environments. Herault et al [11] used 360-degree VR videos to simulate patients with trauma for the teaching of nursing students. The videos were divided into topics such as introducing the medical team, admitting patients into the emergency department, inspecting patients, and monitoring patients' conditions after they have been stabilized. These 4 scenarios supported the learning of students and medical and nursing personnel. Using the number of interactions noted during video coding, the duration of viewing a video, and the questions and answers raised on the basis of a video, the researchers discovered that the students exhibited significant differences in their cognition and learning processes. Hodgson et al [8] developed VR videos on the basis of real-world cases in hospital settings. The VR scenarios involved the interaction between patients and the medical team. Students were immersed in an environment to which they did not usually have access, enabling learning ahead of time. The research results indicated that 65% of the participants reported that discussing VR-based cases increased their learning interests and prepared them for clinical work.

Through a scoping review, Fealy et al [12] explored the effect of using immersive VR in nursing and midwifery education and discovered that using VR for simulated scenario learning provided students with the opportunity for repeated learning, which enhanced students' care ability and confidence. Foronda et al [6] and Shorey and Ng [13] conducted systematic reviews to investigate the effect of virtual simulation teaching on nursing students, nurses, and nursing education. The results revealed that VR for simulated scenario learning could replace or supplement traditional nursing education, with the VR-based method effectively increasing students' cognition and knowledge, skills and performance, critical thinking, self-confidence, and learner satisfaction.

Students can learn from VR simulation scenarios that enable interaction. In this study, we conducted a literature review of domestic and foreign studies and discovered that few studies have explored the use of interactive VR learning and its effect on nursing students' nursing ability and willingness to serve older adults. This study explored self-evaluated nursing ability and willingness to care for older adults in nursing students after they used interactive VR to learn; the influencing factors were also examined. The results can be used to enhance nursing students' nursing ability in terms of older adult care.

The research questions (RQs) of the study are as follows. RQ1: What are nursing students' perceptions of their adoption of interaction-based VR learning? RQ2: What are the nursing students' perceptions of factors (eg, willingness to use VR learning materials for older adult assessment, cognitive load, and willingness to serve for older adult care) that affect the adoption of VR educational technologies?

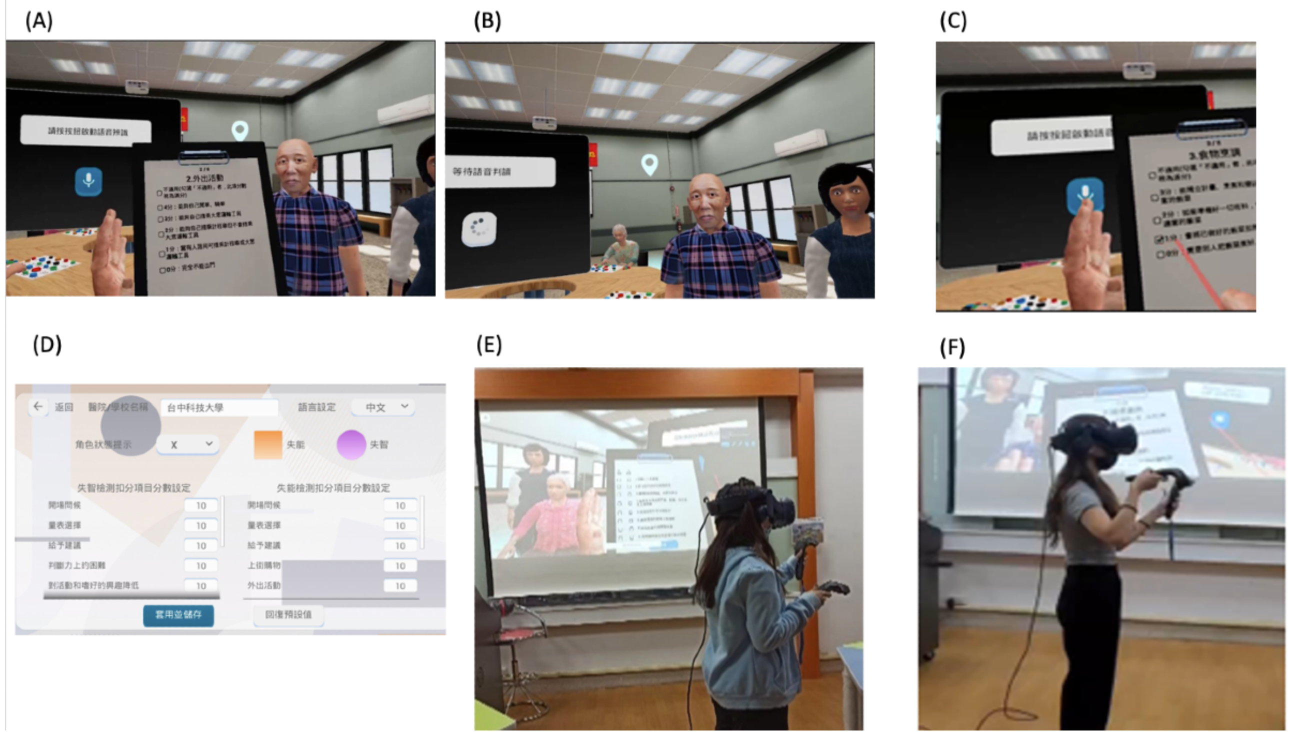
Methods

Research Design and Research Participants

This study adopted a cross-sectional correlation research design. A science and technology university in Taiwan acted as the recruitment site. Purposive sampling was used, and fourth-year students in the nursing department of a 5-year program were recruited as research participants, with those who had suspended their studies excluded. After the participants interacted with the VR-based older adult care assessment system, they completed a questionnaire survey. G*Power software (version 3.1.9.2; Heinrich-Heine-Universität Düsseldorf) was used to estimate the number of research samples. We set the statistical power as .8, type I error (α) as .05, and effect size as .3 (moderate effect). We identified 8 independent variables in this study. The calculation results indicated that the study required a sample size of 121; a total of 130 nursing students were recruited.

The research participants were enrolled in an older adult nursing course. In addition to classroom learning, they were instructed to use interactive VR lessons to experience older adult care. The VR lesson plan consisted of 2 units, namely the Ascertain Dementia-8 assessment and Instrumental Activities of Daily Living scale (IADLs). In the VR scenario, the students could interact with several older adults. The students could choose suitable assessment scales according to the older adults' conditions. For example, if an older adult or primary caregiver reported a decline in the older adult's memory function, then the student could select the Ascertain Dementia-8 assessment to assess the presence of early-onset dementia. If an older adult had reduced activity functions, then the IADLs could be selected. Using voice recognition and a VR images scale, the students could check the correct answers to scenario-based questions. A full test score of 100 was possible, with 60 representing the passing score. The detailed VR operation process is illustrated in Figure 1.

Figure 1. Virtual reality (VR) scenario. (A) Selecting a seated male or female older adult. (B) A caregiver was seated at the older adult's side. The caregiver could assist in answering questions that the older adult could not answer. (C) The assessment checklist was displayed as a virtual image; users could check the assessment items. (D) Backstage scoring system. Each assessment item (eg, Instrumental Activities of Daily Living scale items including ability to use telephone, shopping, food preparation, housekeeping, laundry, mode of transportation, responsibility for own medications, and ability to handle finances) was scored; the full score was 100. (E) and (F) Nursing students engaging in VR learning.



Research Instruments

An anonymous structured questionnaire was used for data collection. All research instruments were applied under the developer's consent. The scales were described as follows.

Personal Attributes and Demographic Information

We composed this part of the questionnaire through referencing the literature. Personal attributes consisted of age, sex, education level, and experiences with using VR to learn.

Willingness to Use VR Learning Materials for Older Adult Care and Assessment

We referenced the scale based on the technology acceptance model developed by Davis and Venkatesh [14], revising this scale to consist of perceived usefulness (6 items), perceived ease of use (3 items), attitude intention to use technologies (3 items), and perceived flexibility (3 items) regarding self-assessed VR-based older adult care learning materials. A 5-point Likert scale was used for assessment, comprising the options of *strongly disagree*, *disagree*, *neutral*, *agree*, and *strongly agree*.

Cognitive Load Scale for Using VR-Based Learning Materials for Older Adult Care and Assessment

Referencing Hwang et al [15] and Paas et al [16], we developed a cognitive load scale consisting of 2 dimensions, namely mental load and mental effort. Mental load was used to assess the perceived burden generated for nursing students when they complete the VR-based older adult care learning tasks. Mental effort was applied to evaluate the degree of cognition and amount of resources required by the nursing students when they complete the VR-based older adult care learning tasks, thereby facilitating the measurement of the perceived difficulty of the learning materials and tasks, the formats in which learning materials were presented, and the students' feelings about the explanation methods. A 5-point Likert scale was used for assessment, comprising the options of *strongly disagree*, *disagree*, *neutral*, *agree*, and *strongly agree*.

Nursing Students' Service Willingness Scale Regarding Older Adult Care

For the nursing students who used the VR lesson to learn to assess older adults, we used a scale to assess their willingness to serve older adults. The questionnaire design referenced that developed by Hsieh et al [17]. This willingness to serve older adults scale comprised 15 items rated on a 5-point Likert scale, ranging from *strongly disagree* to *strongly agree*; the higher the score, the greater the student's willingness to serve older adults. All questionnaire items were direct items. Experts were invited to modify the items to ensure construct validity.

Questionnaire Reliability and Validity

Validity

To ensure the content validity and expert validity of the questionnaire, we invited 3 nursing professors in departments related to older adult care and 2 industry experts to review the adequacy of the content of each scale in the questionnaire. We referenced Polit and Beck [18], who suggested a calculation method for content validity indicators in which items scored higher than 3 by experts are retained. After calculating the percentage, we determined that the content validity index of the willingness to use VR learning materials for older adult care and assessment was .98, that of the cognitive load scale for using VR-based older adult care learning materials was .96, and that of the nursing students' willingness to serve older adults scale was .99. Each scale exhibited favorable content validity.

Reliability

Cronbach α coefficient analysis was applied. The Cronbach α of the willingness to use VR learning materials for older adult care and assessment was .96, that of the cognitive load scale was .98, and that of the willingness to serve scale was .97. All scales exhibited favorable internal consistency.

Ethics Approval

Ethical approval for the study was obtained from the Human Research Ethics Council (CRREC-110-088). The researcher explained the research purpose and process to the participants. To ensure the protection of their personal rights, written informed consent was obtained prior to data collection.

Data Processing and Analysis

This study used the SPSS statistical software (version 23.0; IBM Corp) for data entry and statistical analysis. A P value of <.05 indicated statistical significance. Descriptive statistics involved using the percentage, mean, and SD to present distributions. The independent sample 2-tailed t test, one-way ANOVA, Pearson correlation coefficient, and stepwise regression were used for inferential statistics and analysis.

Results

Descriptive Variables of Research Participants

Of the 130 participants of this study, most (n=126, 96.9%) were women. Most of the participants were aged 19 years (n=66, 50.8%), followed by those aged 18 (n=62, 47.7%) and 20 (n=2, 1.5%) years. A total of 93.9% (n=122) of the participants had previously used VR, but none had used VR learning materials related to the care of older adults.

Participants' Use of VR-Based Learning Materials for Older Adult Care and Assessment and Their Nursing Ability

Regarding the overall research variables, the total mean score of cognitive load during learning was 2.49, that of willingness to use VR learning materials was 4.23, that of nursing ability was 4.25, that of willingness to serve older adults was 3.66, and that of the satisfaction toward the VR learning model was 4.14. The detailed data are presented in Table 1.

Table 1. Participants' use of virtual reality (VR) learning materials to assess older adult care and their nursing ability (N=130).

Research variable, secondary dimension	Secondary dimension, mean (SD)	Total, mean (SD)
Cognitive load during learning		2.49 (0.73)
Mental load	2.45 (0.74)	N/A[a]
Mental effort	2.52 (0.78)	N/A
Willingness to use VR learning materials		4.23 (0.47)
Perceived usefulness	4.42 (0.45)	N/A
Perceived ease of use	4.25 (0.61)	N/A
Willingness to use	3.96 (0.74)	N/A
Flexibility	4.29 (0.49)	N/A
Nursing ability		4.25 (0.48)
Basic and general educational competencies	4.32 (0.50)	N/A
Information management and application ability of nursing care case scenario	4.35 (0.54)	N/A
Health care policies, finance, and environmental capability	4.28 (0.62)	N/A
Care quality, case content safety, and leadership ability	4.18 (0.70)	N/A
Nursing practice ability	4.26 (0.49)	N/A
Preventive health care ability	4.22 (0.54)	N/A
Teamwork ability	4.09 (0.72)	N/A
Risk and quality management ability	3.26 (0.75)	N/A
Ethical ability	3.38 (0.65)	N/A
Willingness to serve older adults	N/A	3.66 (0.40)
Satisfaction toward the VR learning model	N/A	4.14 (0.52)

[a]N/A: not applicable.

Difference Analysis of Demographic Data and Research Variables

The independent sample 2-tailed *t* test was used to explore whether sex-based differences were present among the 4 variables of cognitive load during learning, willingness to use VR learning materials, nursing ability, and willingness to serve older adults; Levene test with equal variance was used to obtain the *F* test values of the 4 aforementioned variables, which were 4.13, .01, .34, and 5.07, respectively. Among them, cognitive load during learning and willingness to serve older adults had *P* values of <.05. Next, the *t* value and significance were used for data analysis. The *t* values of the 4 variables of cognitive load during learning, willingness to use VR learning materials, nursing ability, and willingness to serve older adults were .92, 1.52, 1.23, and –14.53, respectively. Only the *t* value of willingness to serve older adults exhibited a significant difference (*P*<.001). According to the mean values listed in Table 2, women's willingness to serve older adults was significantly higher than that of men (*P*<.001).

Table 2. Sex-based differences in research variables (N=130).

Dimension	Participants, n		Research variable, mean (SD)			*F* test		*t* test	
	Male	Female	Male	Female	*P* value	Value	*P* value	Value (*df*)	*P* value
Cognitive load during learning	4	126	3.00 (1.15)	2.47 (0.71)	.43	4.13	.04	.92 (128,3)	.43
Willingness to use VR[a] learning materials	4	126	4.58 (0.48)	4.22 (0.47)	.13	.01	.91	1.52 (128,3)	.13

Willingness to serve older adults	4	126	3.10 (0.04)	3.68 (0.39)	<.001	5.07	.03	–14.53 (128,43)	<.001

[a]VR: virtual reality.

Correlation Analysis of Cognitive Load During Learning, Willingness to Use VR Learning Material, Nursing Ability, and Willingness to Serve Older Adults

According to the analysis results summarized in Table 3, the correlation coefficient of cognitive load during learning and willingness to serve older adults was –.374 (*P*<.001), indicating that these 2 variables were significantly and negatively correlated. The correlation coefficient of willingness to use VR learning materials and nursing ability was .693 (*P*<.001), indicating that these 2 variables were significantly and positively correlated. The correlation coefficient of willingness to use VR learning materials and willingness to serve older adults was .274 (*P*<.001), indicating that these 2 variables were significantly and positively correlated.

Table 3. Correlation analysis.

Research variable	Cognitive load during learning	Willingness to use VR[a] learning materials	Nursing ability	Willingness to serve older adults
Cognitive load during learning				
r	1	—[b]	—	—
P value	—	—	—	—
Willingness to use VR learning materials				
r	–.122	1	—	—
P value	>.05	—	—	—
Nursing ability				
r	–.006	.693	1	—
P value	.94	<.001	—	—

[a]VR: virtual reality.

[b]Not applicable.

Regression Analysis of Willingness to Use VR Learning Materials and Cognitive Load During Learning on Willingness to Serve Older Adults

We applied regression analysis, and the model variance analysis results in Table 4 indicated that the overall regression model reached a significant level (F_2=15.133, *P*<.001), indicating that the overall regression model was statistically meaningful. After adjustment, the coefficient of determination was .180. Following the *F* test, we conducted an analysis of the regression coefficients of the predictor variables. The results revealed that the standardized regression coefficient (β) of willingness to use VR learning materials was .23 (t_2=2.89, *P*=.005), reaching a significant level; the β of cognitive load during learning was −.35 (t_2=–4.30, *P*<.001), also reaching a significant level. The standardized regression coefficient represented the amount of variance explained by the individual predictor variables for the dependent variables.

Table 4. Regression analysis of willingness to use virtual reality (VR) learning materials and cognitive load during learning on willingness to serve older adults. The adjusted R^2 was 0.18 (F_2=15.13, *P*<.001).

Model	Unstandardized coefficient, B estimation value (SE)	Standardized coefficient beta distribution	*t* test (*df*)	*P* value
Constant	3.30 (.32)	.32	10.36 (2,127)	<.001
Willingness to use VR learning materials	.19 (.07)	.23	2.89 (2,127)	.005
Cognitive load during learning	–.19 (.04)	–.35	–4.30 (2,127)	<.001

Discussion

Participants' Use of VR Learning Materials for Assessing Older Adult Care and Nursing Ability Under Personal Attributes

Among the research participants, 96.9% were women, 50.8% were aged 19 years, and 93.9% had previously used VR but not VR learning materials related to the care of older adults. This result indicates that VR has been widely applied in daily life but little older adult care learning materials had incorporated VR, resulting in few opportunities for students to learn and experience this immersive technology. The overall learning satisfaction of the students using VR learning materials to assess older adult care was high, a result that is in line with those of the systematic literature review of Gasteiger et al [19].

Under the dimension of willingness to use VR learning materials, perceived usefulness scored the highest among all aspects. This result is similar to that of related studies [20-22], indicating that using VR to assist learning reinforced the cognitive level of learners and assisted them in their learning. Regarding the nursing ability dimension, information management and application ability to care for case patients scored the highest among all aspects, indicating that through engaging with the interactive VR scenario, learners' ability to perceive and respond to scenario-based problems was enhanced. The participants could use voice recognition to respond and select the correct care method. The learning process was valuable for the participants' future case management ability, a result echoing those of other studies [22,23].

Significant Correlation Factors of Cognitive Load During Learning, Willingness to Use VR Learning Materials, Nursing Ability, and Willingness to Serve Older Adults

This study revealed sex-based differences in the participants' willingness to serve older adults, with women being significantly more willing to do so than did men. This result may be attributable to the nursing department being composed largely of women, and thus their willingness to care was higher than that of men. This result is in line with that of Guo et al [24].

The mean score of cognitive load during learning in this study was low, reflecting that during the research process, the older adult care assessment learning materials were not perceived as difficult or burdensome by the learners. If participants can be equipped with relevant older adult care knowledge in the classroom before experiencing VR, their cognitive load during learning can be reduced. Notably, cognitive load during learning and willingness to serve older adults were negatively correlated. This result indicated that when teachers choose learning materials, in addition to making selections according to the teaching objectives and content of the professional course, they must also consider the difficulty and appropriateness of the content. During the students' learning process, teachers must adjust the course content according to the learners' cognitive load, thereby increasing learners' learning effectiveness and their willingness to care for older adults. This finding is consistent with those of other studies [17,25,26].

Willingness to use VR learning materials and nursing ability were positively correlated, demonstrating the essentiality of the vividness of the learning environment. Through the use of VR to present a vivid scenario of caring for older adults, the nursing students' ability to provide professional nursing care to older adults was enhanced. From the positive feedback scenario of interactive VR, the opportunities for nursing students to interact with older adults were increased, which reinforced the students' willingness to serve older adults. This research result is in line with those of related studies [21,27-30].

Critical Factors Influencing Willingness to Serve Older Adults

This study discovered that willingness to use VR learning materials and cognitive load during learning were critical factors influencing willingness to serve older adults. This result indicated that engaging in the interactive VR scenario increased the students' willingness to use such materials. Additionally, with VR supporting conventional classroom teaching, students may repeatedly practice older adult care scenarios, allowing them to become familiar with the relevant knowledge on a cognitive level. They can engage in learning without worrying about making mistakes and harming older adults. Thus, students' learning load was reduced, and their problem-solving ability and self-confidence increased. These results are consistent with those of other studies [17,21,27,29-31].

Studies of willingness to serve older adults [10,13,17,24,32,33] have reported that through learning to interact with older adults, nursing students can observe older adults' verbal and nonverbal cues, with such interaction increasing their willingness to serve and care for older adults. This study used VR learning materials, and the results revealed that through the VR simulation scenario, the opportunities for students to interact with older adults were increased. Learning through VR scenarios can reduce students' anxiety when communicating with older adults in a real-world context, thereby increasing students' willingness to serve older adults.

Limitations

This study had some limitations. The respondents provided subjective responses, which could sometimes obscure their actual intention, and more male participants should have been included in the study. Moreover, this study was a quantitative study, which increased the difficulty of understanding the nursing students' willingness to serve older adults.

Conclusions

This survey of 130 preregistered nurses explored factors affecting their willingness to serve older adults. The most influential factors were willingness to use VR learning materials and cognitive load during learning, both of which can be enhanced through older adult care–related courses and practical experience. Nurses play a critical role in the care of older adults, and courses on older adult care are thus crucial for developing sufficient professional human resource capacity. We recommend that VR case scenarios about older adult nursing assessment be incorporated into in-service education. Through repeated practice using these scenarios, nurses' willingness and ability to care for and serve older adults can increase. Longitudinal follow-up studies of recent nursing graduates (preregistered nurses) who had engaged in VR-based older adult care courses must be conducted to elucidate these courses' effects on nurses' older adult care competence and willingness to serve older adults.

Acknowledgments

We sincerely express our appreciation to the experts in the geriatric nursing education fields and their academic, policy, and workforce knowledge for helping us adapt the questionnaire to the context and for assessing the content validity of the questionnaire.

We are grateful for the funding we received from the Ministry of Education and the Ministry of Science and Technology (110-2511-H-025-007). The funders had no role in the design of the study; in the collection, analyses, and interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

Authors' Contributions

PLH and YRW was responsible for the study idea and design. PLH were responsible for the drafting of the manuscript. TCH supported the technical detail problems of the virtual learning system. PLH performed the data collection. YRW and PLH performed the data analysis. PLH made critical revisions to the paper for important intellectual content. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The potential risk and subsequent impact of serious complications after pancreatic and colorectal surgery can be significantly reduced through early recognition, correct assessment, and timely initiation of appropriate therapy. Serious gaming (SG) is an innovative teaching method that combines play with knowledge acquisition, increased concentration, and quick decision-making and could therefore be used for clinically oriented education.

Objective: This study aims to develop a case-based SG platform for complication management in pancreatic and colorectal surgery, validate the application by comparing game courses of various professional groups in the health care sector, and test the acceptance of the developed platform in the context of clinical education by measuring levels of usability and applicability within the framework of a validity and usefulness analysis.

Methods: In this observational trial, a novel SG for management of postoperative complications was developed and prospectively validated in a cohort of 131 human caregivers with varying experience in abdominal surgery. A total of 6 realistic patient cases were implemented, representing common complications after pancreatic and colorectal surgery. Cases were developed and illustrated using anonymized images, data, and histories of postoperative patients. In the prospective section of this study, following a brief case presentation, participants were asked to triage the virtual patient, make an initial suspected diagnosis, and design a 3-step management plan, throughout which the results of selected diagnostic and therapeutic actions were presented. Participants' proposed case management was compared to ideal case management according to clinical guidelines. Usability, applicability, validity, and acceptance of the application were assessed using the Trier Teaching Evaluation Inventory as part of a noncomparative analysis. In addition, a comparative analysis of conventional teaching and learning formats was carried out.

Results: A total of 131 cases were answered. Physicians selected more appropriate therapeutic measures than nonphysicians. In the Trier Teaching Evaluation Inventory, design, structure, relevance, timeliness, and interest promotion were predominantly rated positively. Most participants perceived the application to be superior to conventional lecture-based formats (training courses, lectures, and seminars) in terms of problem-solving skills (102/131, 77.9%), self-reflection (102/131, 77.9%), and usability and applicability (104/131, 79.4%).

Conclusions: Case-based SG has educational potential for complication management in surgery and could thereby contribute to improvements in postoperative patient care.

Introduction

Advanced inflammatory [1] or malignant [2,3] diseases of the pancreas or colorectum usually require surgical intervention. Unpreventable postoperative complications occur in up to every second abdominal surgery due to the severity and complexity of the procedure and patients' general frailty [4,5]. Correct and rapid classification of symptoms is essential for the recognition and treatment of postoperative complications [6] such as postpancreatectomy hemorrhage [7], a potentially life-threatening complication after pancreatic surgery [8]. In such situations, misjudgments are directly associated with increased morbidity and mortality [2]. As the risk, severity, and subsequent impact of postoperative complications could be significantly reduced through early recognition, correct assessment, and timely initiation of appropriate therapy, the training of situation awareness and decision-making processes has the potential to translate into manifest clinical benefit [9].

In clinical practice, physicians face challenges related to rapidly changing health care systems and the need to constantly keep up with scientific advances [10]. Outdated doctrines can result in suboptimal care and medical errors [11]. Therefore, the establishment of new didactic formats can contribute to the maintenance of high standards, prove the effectiveness of innovative methods, and gain user acceptance [12,13]. Clinically oriented education aims to strengthen the theoretical, practical, and communication skills of medical staff and to prepare and motivate them for lifelong continuing training [14]. Various teaching methods with distinct characteristics can be combined to best achieve these goals [13,15]. Serious gaming (SG) is an innovative teaching method that combines play with knowledge acquisition, increased concentration, and quick decision-making [16,17]. The strengths of SG lie in the acquisition and subsequent transfer of procedural skills as well as declarative knowledge [18]. In addition, SG is suitable for teaching the peculiarities of individual cases, such as gender- or ethnicity-specific disease patterns, thus increasing awareness and raising consciousness. Recent evidence suggests that by implementing these aspects, both student education per se and the quality of patient care can be improved [19]. Traditionally, medical teaching takes place in person and offers relatively little interaction between students and teachers. During the COVID-19 pandemic, the need to digitize and restructure established formats has grown substantially, and both educators and students have realized that web-based teaching is not only feasible but also offers many advantages and opportunities, including independence in place and time and the promotion of cooperative learning [20]. Digital education options offer the potential to integrate recent evidence, contributing to lifelong learning and lasting knowledge. Considering the necessity not only to generate and make knowledge available but also to manage it, the potential of digital education has not yet been exhausted [21].

This project aims to develop and validate a scalable, case-based SG platform for clinical education of postoperative management targeting health care professionals throughout different stages of training. Ultimately, the aim is to improve the quality of care for hospitalized patients by increasing health care professionals' capability to transfer knowledge to specific disease contexts and thus provide sensitized care.

Methods

Structure and Development of the SG

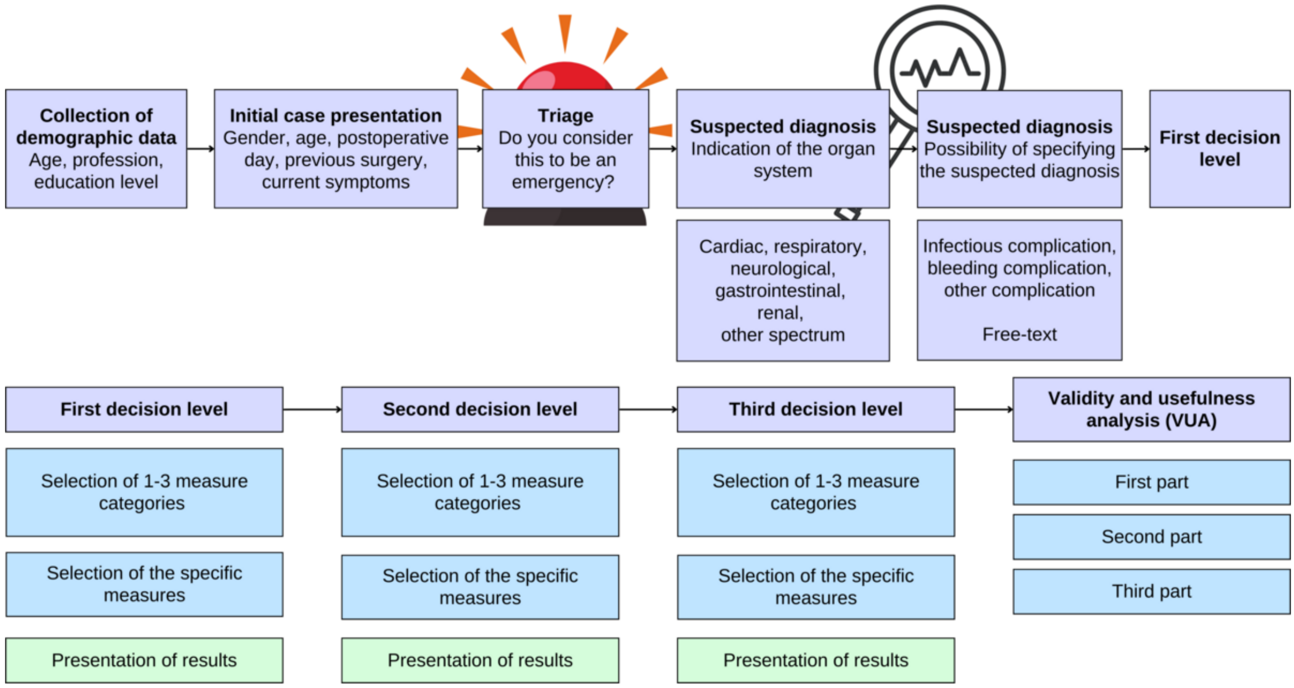
The SG was designed as an anonymized, prospective, open, observational study based on a voluntary web-based survey constructed with REDCap (Research Electronic Data Capture; Vanderbilt University) [22]. Participants included hospital staff with patient contact and medical students in German-speaking countries, and the study was carried out in German. A total of 6 independent SG cases were implemented. The cases represented complications after pancreatic surgery (postpancreatectomy hemorrhage or postoperative pancreatic fistula [POPF]), colorectal surgery (anastomotic leakage or mechanical ileus), and general postoperative complications (eg, stroke, wound infection, and COVID-19 infection). These 6 cases of postoperative complications were selected based on their rate of occurrence [23] and severity, as well as their potential to identify and respond to early clinical symptoms. Initial case selection took place with a drop-down menu that included brief case descriptions (ie, "4th postoperative day after ileostomy reversal, muscular defense" for the case on anastomotic leakage).

The SG platform allowed participants to plan and carry out diagnostic and therapeutic measures for fictitious postoperative patients who presented with new symptoms. After selecting 1 or more measures, participants were presented with the results of the respective diagnostic or therapeutic actions and could adjust their further actions accordingly. A total of 108 diagnostic and therapeutic measures, grouped into 16 measure categories, were available per selection level and case. Multimedia Appendix 1 gives an overview of measures and measure categories.

For case illustration, completely anonymized photographic images of visible disease symptoms or signs, laboratory parameters, imaging data, or other diagnostic tests of patients from the Department of Visceral, Thoracic, and Vascular Surgery at the University Hospital Carl Gustav Carus Dresden who underwent pancreatic or colorectal surgery between 2015 and 2021 were used.

For general statistical evaluations, demographic data were collected at the beginning of each game case. The following initial case presentation provided patient information. Subsequently, participants were asked to make a suspected diagnosis and select initial diagnostic and therapeutic measures from a list. The measure results were presented directly after selection. This was followed by 2 more decision levels, with the first level representing the acute, the second the definitive, and the third the long-term management of the suspected complication (Figure 1).

Figure 1. Serious gaming case structure. Introductory part: from the collection of demographic data of the participant to the first decision level. Main part includes 3-step case management and validity and usefulness analysis.



Between levels, participants were asked to change or narrow down their current suspected diagnosis, mandatorily indicating a suspected affected organ system and offering further specification of the complication mechanism and the complication itself. Furthermore, it was recorded whether the participants considered the case at hand to be an emergency (binary question). Each case was concluded with a validity and usefulness analysis (VUA).

VUA Framework

The first part of the VUA was based on the Trier Teaching Evaluation Inventory (Figure 1). The second part allowed a comparison of the application to existing lecture-based teaching and learning. The third part enabled an evaluation of the expected knowledge gain in comparison with common theoretical or practical learning formats. Finally, the case was to be evaluated with a grade (1=best to 6=worst grade).

All answers were given by means of a fully verbalized, 5-point, balanced scale (eg, scale end points of the first part: "agree," "rather agree," "undecided," "rather disagree," and "disagree"; second and third part: "SG is superior," "SG is rather superior," "undecided," "SG is rather inferior," and "SG is inferior").

Participant Recruitment

Pilot-testing and evaluation of the SG took place from December 2021 to February 2022. We aimed to recruit a diverse cohort of health care professionals as potential users of our application. To this end, the SG was advertised through various channels, including direct email advertisements to medical and nursing staff of the University Hospital Carl Gustav Carus Dresden and students of the Medical Faculty Carl Gustav Carus Dresden, web-based portals of the Technical University Dresden, and direct information events. Participants not affiliated with the University Hospital Dresden were reached by email through appropriate mailing lists (eg, mail distribution lists of German clinics). Participants were recruited from the entire German-speaking area, and the study was carried out in German.

The prerequisite for participation was the ability to give informed consent and the informed consent itself. Only fully answered cases were included in the final analysis.

Ethical Considerations

This study was carried out in accordance with the Declaration of Helsinki and its later amendments. The Ethics Committee of the Technical University Dresden reviewed and approved this study (BO-EK-378072021). Before participation, all participants consented to anonymized data acquisition, data analysis, and publication of the results.

Game Process Evaluation and Statistical Analysis

The SG case itself and the subsequent VUA were evaluated separately. The general statistical evaluation comprised a descriptive evaluation of the participant cohort, an evaluation of processing times, and a comparative evaluation of differences in case duration and duration of processing time of individual management levels between occupational and educational groups using ANOVA. Initial and final suspected diagnoses were evaluated using descriptive statistics, with free-text statements classified as "correct," "incorrect," and "not specified." The results were displayed using frequency distributions by case and occupational group.

In order to analyze the appropriateness of management decisions, an ideal solution path was elaborated for each case, corresponding to a specific sequence of diagnostic and therapeutic measures. Besides this ideal solution path, 1 measure was defined as crucial for each SG case, that is, essential for the recovery of the fictitious patient, by 2 surgical experts with over 15 years of clinical experience in general and abdominal surgery (TW and MD). This therapeutic action was used to assess appropriate, exaggerated, and understated therapy escalation. The appropriateness of the selected therapeutic pathway was rated based on all clinical decisions made throughout the course of the SG case. These evaluations were based on valid German or European guidelines [7,24-26], expert opinions, and publications, as well as existing evidence on complication management in abdominal surgery, to ensure medical correctness and contextual coherence as well as a straightforward and realistic initial presentation. The ideal paths with the appropriate therapeutic measures for all cases as well as initial case presentations are presented in Multimedia Appendix 2, and measure categories and individual measures are presented in Multimedia Appendix 1. Final diagnoses had to be given in free-text format.

VUA results were summarized using descriptive statistics. Raw data were exported directly from REDCap [22] and are provided in Multimedia Appendix 3. The subsequent statistical analysis and illustration were performed using R software (R Foundation for Statistical Computing) [27], GraphPad Prism (version 9; Dotmatics) [28], and Canva (Canva Inc) [29]. Significance in groupwise comparisons was assessed using ANOVA (for numerical variables) and the Fisher exact test (for categorical variables), with $P<.05$ considered statistically significant.

Results

Participant Cohort and Processing Time

A total of 131 SG cases were completed in the desktop-based SG application (Multimedia Appendix 4). Overall, the participant cohort reflected the entire spectrum of health care professionals with the largest proportions; 57% (74/131), 15% (20/131), and 14% (18/131) of cases were completed by medical students, nursing and other clinical staff with patient contact, and experts, respectively (Multimedia Appendix 5). The age group of 21-25 years was most frequently represented (45/131, 34%), and the average age of the participants was 30.8 (SD 10.4) years (Multimedia Appendix 4). On average, a single SG session took 11 minutes and 46 seconds. No significant differences regarding the duration were found between cases (P=.68; Multimedia Appendix 6), age (P=.46; Multimedia Appendix 4), or occupational groups (P=.33; Multimedia Appendix 5).

In addition, a cross-case analysis was performed comparing the time needed per measure stage, which was defined from the beginning of the selection of the measure top categories per stage until the presentation of the results of the respective stage. The analysis showed a significant difference in processing time. On average, participants needed 1 minute and 25 seconds for the first stage, 53 seconds for the second stage, and 30 seconds for the third stage (all $P<.001$; Table 1).

Table 1. Average duration of serious gaming cases with respect to management level.

3-step case management	Average duration	*P* value
Acute management	1 min 25 s	<.001
Definitive management	53 s	<.001
Long-term management	30 s	<.001

SG Cases Discriminate Between Professions and Surgical Expertise

The implemented SG cases were of varying difficulty and were capable of discriminating between varying surgical expertise. A total of 121 (92.4%) out of 131 participants selected the correct organ system at the initial assessment (Figure 2). When other optional specification levels were used, the result was predominantly correct (correct specification of complication mechanism: 77/88, 88%; Figure 3; correct specification of exact complication: 29/33, 88%; Figure 4).

All participating experts and board-certified surgeons correctly selected the suspected organ system after the initial patient presentation (Figure 2), demonstrating that case presentations provided sufficient information for surgical experts to conclude relevant details about the virtual case. In contrast, medical students and nonphysician caregivers selected incorrect organ systems more frequently. This demonstrates that varying surgical expertise was mirrored by the differences in correct case interpretation. The final diagnoses given at the end of the game also correlated with the participants' level of training. In the final step of each case, physicians gave the correct diagnosis in all cases (Multimedia Appendices 7-12).

Based on the results of medical students and other staff, the cases varied in difficulty. The COVID-19 and wound infection (Multimedia Appendix 11) case was ultimately correctly interpreted by all participants, and most participants correctly diagnosed the virtual patients with stroke (16/19, 84%; Multimedia Appendix 8) and ileus (9/10, 90%; Multimedia Appendix 10). In contrast, sentinel hemorrhage (Multimedia Appendix 12), POPF (Multimedia Appendix 9), and 2 pancreatic surgery-specific complications were misspecified by 67% (12/18) and 43% (6/14) participants, respectively, with marked differences between physicians and other participant groups.

Figure 5 summarizes the case-specific therapy escalation. Overall, the assessment of therapy escalation led to particular difficulties in case 3 (POPF) and 4 (mechanical ileus). Case 5 (COVID-19 and wound infection), on the other hand, was correctly assessed by the great majority (17/19, 89%) of participants.

Figure 2. Interprofessional evaluation of the initially specified suspected diagnosis by suspected organ system across all serious gaming cases. Specification of the organ system was mandatory, while specification of complication mechanism and exact complication were voluntary.

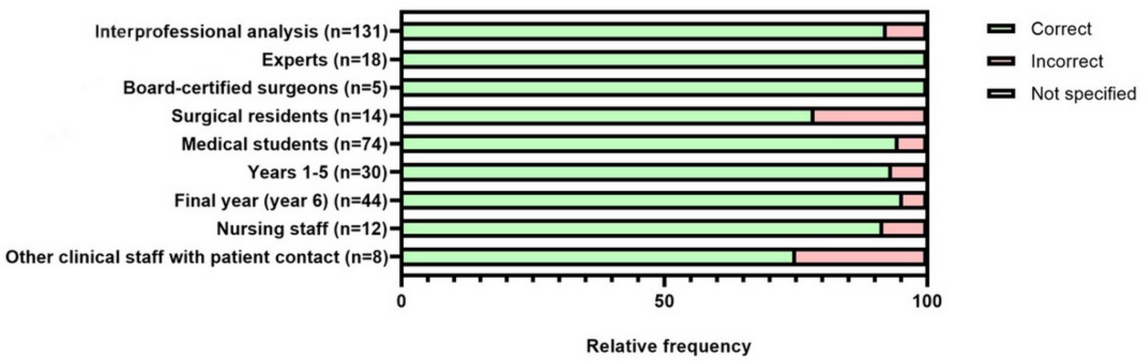


Figure 3. Interprofessional evaluation of the initially specified suspected diagnosis by suspected complication mechanism across all serious gaming cases. Specification of the organ system was mandatory, while specification of complication mechanism and exact complication were voluntary.

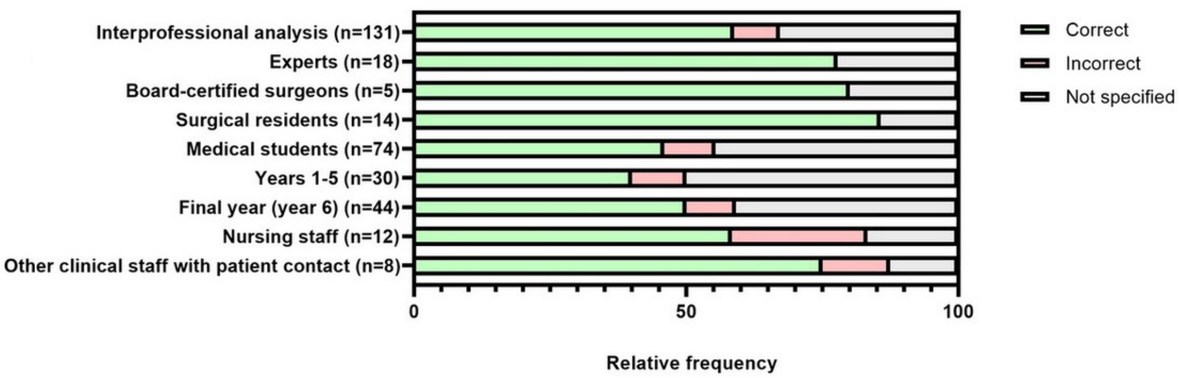

Figure 4. Interprofessional evaluation of the initially specified suspected diagnosis by suspected exact complication across all serious gaming cases. Specification of the organ system was mandatory, while specification of complication mechanism and exact complication were voluntary.

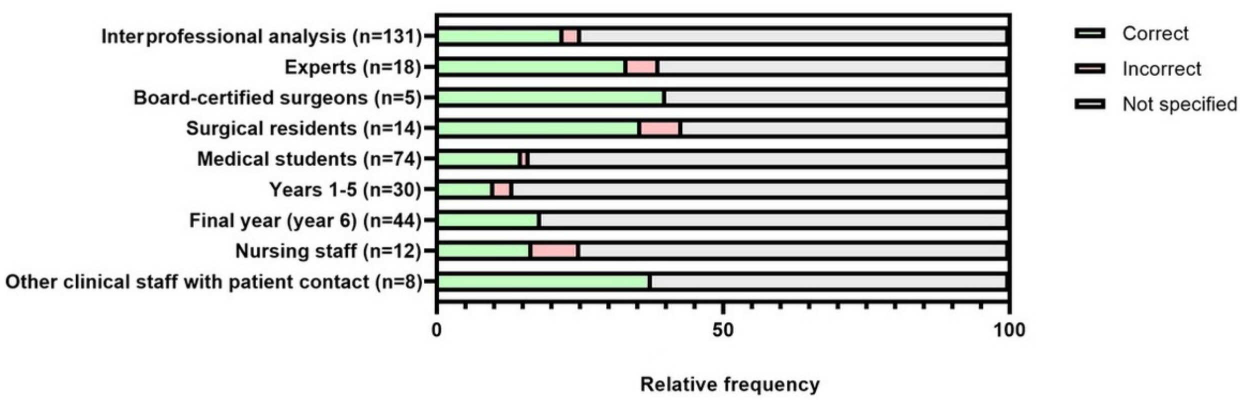

Figure 5. Case-specific evaluation of therapy escalation. In order to analyze the appropriateness of management, 1 therapeutic measure was defined as crucial for each serious gaming case based on valid guidelines. POPF: postoperative pancreatic fistula.

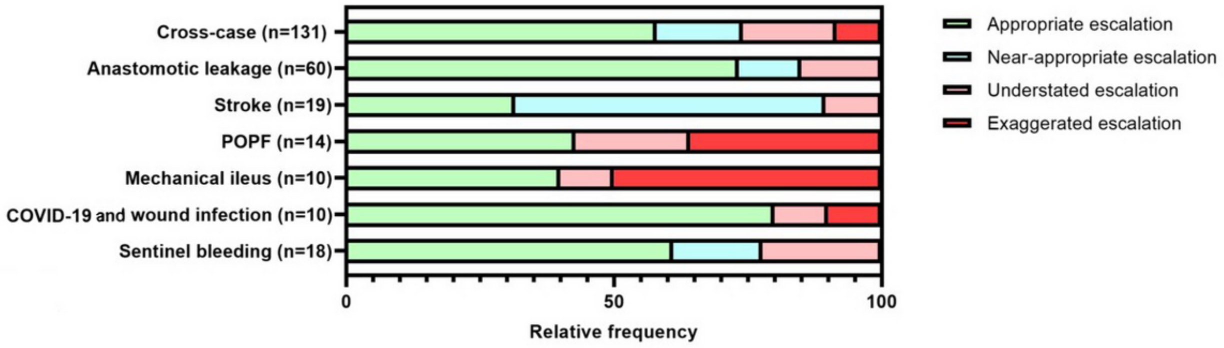


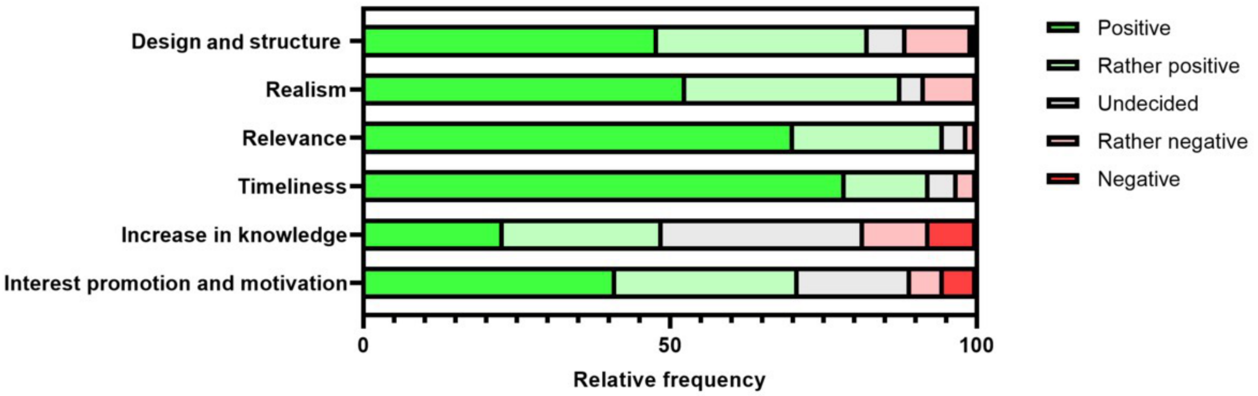
Multimedia Appendices 13-18 display the case-specific therapy escalation stratified by occupational and educational group.

SG Is Accepted by Health Care Professionals

The goal of the VUA was to determine how instructive and user-friendly participants perceived the case-based SG application to be. Overall, design, structure, realism, relevance, and timeliness were predominantly rated positively (Figure 6). Interest promotion and motivation for autodidactic workup and estimated increase in knowledge were rated lower compared to the aforementioned dimensions. The detailed results of the VUA are summarized in Multimedia Appendix 19.

Most participants perceived case-based SG to be superior to conventional lecture-based learning and teaching formats (training courses, lectures, and seminars) in terms of increasing problem-solving skills (53/131, 41% perceived it superior; 49/131, 37% perceived it rather superior), self-reflection (50/131, 38% perceived it superior; 52/131, 40% perceived it rather superior), and usability and applicability (55/131, 42% perceived it superior; 49/131, 37% perceived it rather superior). Overall, 74 (57%) out of 131 participants perceived the SG application to be superior (26/131, 20% perceived it superior; 48/131, 37% perceived it rather superior) to these conventional teaching formats with regard to the gain of theoretical competencies, while 26 (20%) out of 131 participants did not see any difference. Overall, the case-based SG was rated "good" ("2") or better in 78% (102/131) of cases (Multimedia Appendix 19).

Figure 6. Results of the noncomparative validity and usefulness analysis. After completing a serious gaming case, participants were asked to rate it across several dimensions using a 5-point scale.



Discussion

Principal Findings

This study presents a new didactic implementation of case-based learning (CBL) as a SG for medical education in the field of identification of surgical complications and validates this implementation in a representative cohort of participants with varying medical experience and expertise. Overall, the case-based SG format was well-accepted, and the majority of participants rated the platform as superior to traditional formats in terms of problem-solving skills, self-reflection, usability and applicability.

Comparison to Previous Work

Postoperative complications are a part of the perioperative process that can only be prevented to a limited extent [9]. Timely recognition and straightforward treatment initiation are crucial to optimizing patient outcomes [2]. One limitation of conventional didactic methods lies in the poor transfer of theory into practice [30]. SG has the potential to markedly improve this transfer by teaching medical decision-making, training a systematic and complete approach, building up automatisms, and transferring these into a virtual action [31].

Complications after surgical interventions are common and closely linked to higher morbidity and mortality [2,3]. Despite knowledge about predisposing factors and early warning signs, clinical management guidelines generally leave room for individualized decisions that take clinical circumstances into consideration. In terms of such diagnostic and therapeutic decisions (ie, diagnostic computer tomography scan or application of antibiotics), a recent large-scale study [32] has compared a decision-making algorithm to standard care in the context of postoperative complications after pancreatic resection. Here, the algorithm-directed initiation of diagnostic and therapeutic measures resulted in a significantly reduced 90-day mortality rate, indicating that logic-triggered decision-making has the potential to improve clinical outcomes in postoperative care. The presented case-based SG platform could contribute to an integration of such knowledge and "quasi-algorithmic" decision-making into medical education, which could result in improved identification of early warning signs of serious complications after major abdominal surgery.

In aviation and military training, simulations (ie, flight simulators) have been an integral part of training curricula for over a century [33]. Adapted to the growing demand for digital and combined teaching concepts [34], the interest in SGs is currently growing in the field of medicine too [12]. Cases present a combination of theory and practice and can prepare users for clinically acute and challenging situations, with growing evidence suggesting the effectiveness of CBL [35,36]. Medical SGs address different specialties (surgery [37], internal medicine [38], etc) and target groups (patients [39], physicians [40], nurses [41], and students [18]) and vary regarding the type of application (web-based [42], virtual, or augmented reality [43]). To date, no comparable case-based SG for complication management in surgery is available. Existing works in the field of surgery mostly aim at training laparoscopy or other specific practical skills [37] and focus less on cases requiring complex multilevel management.

SG facilitates training under near-realistic conditions without the risk of harming patients [44]. Moreover, it has the potential to raise awareness about medical errors and, therefore, ultimately, reduce health care use and costs. Specific and rare medical scenarios are reproducible, which is challenging to teach in theoretical curricula. The strengths of SG lay in building up strategic and analytical skills and to train decision-making. As such, better attitudes toward learning and increased enthusiasm for learning were reported in individuals taught with SG in comparison to those taught with a written script [36,45].

The proposed platform does not impose any requirements for the end device, facilitating mobile, time- and place-independent, and inexpensive usage. In contrast, existing SG applications often rely on equipment that is prone to failure, expensive to develop and implement, and has limited scalability and availability [46]. Our overall results add to the growing body of evidence that CBL and SG have the potential to increase learning fun, which are important precursors for motivation and success [47,48]. Upscaling of the platform through transfer into other medical specialties or inclusion of other professional contexts of patient care, as well as an adaptation to rapidly updating medical evidence, are possible extensions of this work that are being investigated in follow-up trials.

In line with these findings, participants perceived the proposed SG application to be superior to traditional learning formats such as lectures with regard to gaining clinical and problem-solving skills and empowerment for self-reflection as well as higher joy in learning.

Strengths and Limitations

The study results suggest that case-based digital SG could be a relevant addition to existing learning formats in the context of multimodal learning in medical education. The major strengths of the proposed SG application are its realism, topicality, and uncomplicated applicability and handling. The only dimensions of the VUA in which the SG platform was rated positive or superior in less than 50% of the cases were those of estimated increase in knowledge gain. These lower ratings in terms of subjectively perceived learning gains present a weakness of the SG format, which may be partially inherent to the methodology used. Rather than assessing concrete knowledge acquisition, we explored the subjective impact on learning. Future studies may gauge SGs' impact on learning through diverse methods, such as multiarm interventions comparing SG with traditional approaches and long-term assessments including multiple-choice questions, clinical scenarios, simulator-based performance, practical exams, and Objective Structured Clinical Examinations. Still, learning is characterized by an interplay of different modalities that complement each other.

The limitations of this study are mostly related to the study design. First, the generalizability of the results is limited since participation was voluntary. As a consequence, the validation of the presented case-based SG platform primarily included interested individuals. Due to the voluntary participation, the subgroup sizes were variable and, in some cases, small, rendering subgroup analyses impossible. These sources of bias could be eliminated through other modes of inclusion, that is, cohort inclusion in the context of mandatory classes or a cross-sectional study with mandatory participation, improving the representativity and homogeneity of subgroups. Second, the representation of selectable diagnostic and therapeutic measures in the form of a finite list could have introduced bias, as participants could be guided in both a favorable (ie, toward correct measures) and an unfavorable direction (ie, toward wrong measures). In the future, enhancement could be achieved by substituting drop-down menus with free-text fields. These would facilitate more individual responses without the risk of influencing participants' decision-making process. The results would therefore be more likely to mirror the unbiased thought process, but this process would make evaluation substantially more challenging. To provide quick and reliable feedback for free-text fields within a game, artificial intelligence–based language processing methods could be integrated to filter and categorize the free-text responses in terms of content [49,50], providing respective feedback. Additionally, a human expert review process could be connected with such automated feedback, which could be used in the case of difficulty classifying certain answers. Third, realistic conceptualization of cases was time- and labor-intensive and required an expert review process to guarantee case quality. Simplifying this procedure could be accomplished by implementing a standardized and user-friendly input interface for health care professionals, coupled with a structured and straightforward review process to guarantee medical accuracy and relevance. Third, our platform, similar to most other SGs in medical education, primarily analyzes knowledge gain, skill enhancement, attitudes, and satisfaction within a testing scope [12]. Future studies should venture an implementation attempt into real teaching with the aim to prove the effectiveness and clinical impact of the format and to map a learning curve after a longer period of participation.

Despite these limitations, this study introduces an innovative, scalable combination of case-based learning and SG with high educational potential, particularly in the context of clinical decision-making in the context of complication management in pancreatic and colorectal surgery.

Future Directions

Until now, medical SGs, including our platform, primarily analyze knowledge gain, skill enhancement, attitudes, and satisfaction within a testing scope [12]. Future studies should venture an implementation attempt into real teaching with the aim to prove the effectiveness and clinical impact of the format and to map a learning curve after a longer period of participation. To boost knowledge gained through SG, various extensions, like stronger game characteristics, could potentially be integrated into these continuing studies, such as a coaching simulated senior physician to request advice from during the game.

Conclusion

This study explores the use of SG in medical education, particularly for teaching surgical complication management. Using a desktop-based SG application, we assessed its effectiveness and acceptance among health care professionals. The findings reveal various strengths of the proposed case-based SG platform. The application presents real postoperative complications, allowing users to enhance their decision-making skills without risk. This approach enhances early complication identification, which could ultimately contribute to the sensitization of caregivers and better patient care and outcomes after abdominal surgery.

Acknowledgments

The authors would like to thank all the study participants who took part in the validation trial. This work has been funded by the German Research Foundation DFG within the Cluster of Excellence EXC 2050: “Center for Tactile Internet with Human-in-the-Loop (CeTI)” (project number 390696704). Furthermore, FRK received funding from the Medical Faculty of the Technical University Dresden within the MedDrive Start program (grant 60487) and from the Joachim Herz Foundation (Add-on Fellowship for Interdisciplinary Life Science).

Data Availability

The case descriptions and ideal clinical pathways are available in Multimedia Appendix 2. Participant data gathered in the context of this work are available in Multimedia Appendix 3.

Authors' Contributions

S-CS contributed to conceptualization, data curation, formal analysis, funding acquisition, investigation, methodology, project administration, software, validation, visualization, writing the original draft. MD and TW were involved in conceptualization, funding acquisition, investigation, resources, supervision, validation, writing, reviewing, and editing. GK-J contributed to funding acquisition, project administration, writing, reviewing, and editing. JW was involved in funding acquisition, resources, supervision, writing, reviewing, and editing. FRK contributed to conceptualization, formal analysis, funding acquisition, investigation, methodology, project administration, software, supervision, validation, visualization, writing the original draft.

Abstract

Background: As cancer treatment methods have diversified and the importance of self-management, which lowers the dependence rate on direct hospital visits, has increased, effective cancer care education and management for health professionals and patients have become necessary. The metaverse is in the spotlight as a means of digital health that allows users to engage in cancer care education and management beyond physical constraints. However, it is difficult to find a multipurpose medical metaverse that can not only be used in the field but also complements current cancer care.

Objective: This study aimed to develop an integrated metaverse cancer care platform, Dr. Meta, and examine its usability.

Methods: We conducted a multicenter, cross-sectional survey between November and December 2021. A descriptive analysis was performed to examine users' experiences with Dr. Meta. In addition, a supplementary open-ended question was used to ask users for their suggestions and improvements regarding the platform.

Results: Responses from 70 Korean participants (male: n=19, 27% and female: n=51, 73%) were analyzed. More than half (n=37, 54%) of the participants were satisfied with Dr. Meta; they responded that it was an interesting and immersive platform (n=50, 72%). Less than half perceived no discomfort when using Dr. Meta (n=34, 49%) and no difficulty in wearing and operating the device (n=30, 43%). Furthermore, more than half (n=50, 72%) of the participants reported that Dr. Meta would help provide non–face-to-face and noncontact services. More than half also wanted to continue using this platform in the future (n=41, 59%) and recommended it to others (n=42, 60%).

Conclusions: We developed a multidomain metaverse cancer care platform that can support both health professionals and patients in non–face-to-face cancer care. The platform was uniquely disseminated and implemented in multiple regional hospitals and showed the potential to perform successful cancer care.

Introduction

Cancer is a major global public health concern. There were approximately 19.3 million new cancer cases and 10.0 million cancer deaths globally in 2020 [1,2]. In South Korea, there were nearly 250,000 and 80,000 of such cases, respectively, in 2019 [3]. Although this disease is closely related to significant psychosocial burdens, it can be cured through early diagnosis or effective cancer treatment [4]. Thus, effective cancer education and care, which can lead to appropriate diagnosis and treatment, are important for the successful management of the disease. The dissemination of knowledge to train health professionals has become vital, especially because the types, symptoms, and treatments of cancers have diversified [5]. In addition, as the implementation of traditional cancer care methods has become difficult owing to the spread of infectious diseases such as COVID-19, self-management and home care have become more critical [6,7]. Digital health care is emerging to rapidly diffuse knowledge and is essential for cancer care.

The rapid development of information and communication technologies has accelerated digital transformation in the health care field. The world is seeking to overcome hostile environments such as the crisis of a superaged society, the outbreak of new infectious diseases, and the disparity in medical resources through digital health care [8-10]. Several studies have revealed the effectiveness of broadly applying digital health care services, including mobile health, telehealth using wearable devices, big data analytics, and artificial intelligence, to prevent and treat various diseases and maintain health [11,12].

As the digital health care industry based on innovative and evolving computing technology is expanding, metaverse technologies (eg, virtual reality [VR], augmented reality [AR], mixed reality [MR], and extended reality [XR]) that make the virtual and real worlds converge and interact are drawing attention as playing a key role in the future of digital health care [13-15]. VR is a technology that allows people to experience the real-like world in a computer-generated virtual world. AR creates an interactive environment by overlapping virtual 2D or 3D objects with the real world. In VR, users are blocked from the real world and are fully immersed in a virtual environment. However, in AR, users can simultaneously interact with virtual objects in the real world [13,16]. MR is a technology that merges real- and virtual-world elements and creates a concurrent virtuality continuum by combining the 2 worlds. In AR, virtual objects are superimposed on the real world and provide additional information such that users can see the natural environment, in which the virtual objects necessary to deliver information are placed. In MR, however, the real and virtual worlds are synchronized so that users can interact with targets in both the physical and virtual components of this shared environment [13,16]. This higher level of linkage boosts the advantages of VR and AR, making users feel that virtual components are physically present in the real world. XR is a comprehensive technology that encompasses a wide range of immersive and interactive technologies including VR, AR, and MR [13,16].

In the metaverse, people can interact with each other and digital objects in real time through avatars and engage in diverse activities, such as education, entertainment, counseling, and socializing. Metaverse provides a more immersive and interactive experience than traditional online services. In metaverse situations, users can move around and interact with digital objects, creating a sense of presence that is not possible in text-based chats or video calls [17,18]. In addition, metaverse services offer more creativity than traditional online services. In this metaverse, users have greater freedom to express themselves creatively through their avatars, build their own virtual environments, and design a wide range of virtual objects, which is not possible in a video call or traditional online game [17,18]. In addition, metaverses provide a more life-like social experience based on a more engaging way of interacting with each other than traditional online services. In this metaverse, users can explore virtual spaces, attend events, and interact with others in a way that feels more natural and authentic, which is not possible through video calls or traditional social network services [17,18]. Therefore, metaverse services can be considered to be superior to traditional online services. However, choosing a metaverse does not necessarily mean completely excluding traditional online services. A metaverse can integrate different types of online services such as videoconferencing, social media, and gaming into a single virtual space. Consequently, users can have seamless and cohesive online experiences across multiple metaverse platforms [17,18]. Although traditional online services are valuable tools for many users, through a new and transformative platform, they offer unique benefits that are not available through existing digital technologies. Previous studies have argued that metaverse technology can successfully meet the demand for non–face-to-face medical services and improve health care quality [16,19-24].

As part of efforts to scrutinize the reasons for using metaverse technology and its effectiveness, research has been conducted to identify the factors associated with the use of metaverse. Many previous studies have applied the technology acceptance model (TAM), well-known as a theoretical framework for predicting the use of new information technologies, to understand the use of metaverse better. The TAM posits that an individual’s perceived usefulness and perceived ease of use of technology determine intention to use, which consequently impacts actual use [25]. This model has been expanded by including new external and contextual factors and different factors from other theories to enhance its explanatory power in various contexts [26]. The findings of existing studies have confirmed that TAM-based factors such as perceived usefulness, perceived ease of use, and intention to use are closely associated with the use of metaverse [27-29]. In addition, according to other prior studies examining metaverse use, perceived enjoyment [30] and perceived immersion [31], whether directly or indirectly, may positively influence intention to use, while cybersickness [32] may negatively impact intention to use. Several metaverse studies have also demonstrated a positive relationship between satisfaction and intention to use [33,34]. To sum up, perceived usefulness, perceived ease of use, intention to use, perceived enjoyment, perceived immersion, and satisfaction are likely associated with using metaverse. Our research focuses on these potential variables in developing the metaverse platform and investigating its user experience.

Furthermore, the effectiveness of metaverse technology has been discussed in the context of cancer. VR, AR, and MR benefit health professionals when applied to develop and use educational or surgical tools [35,36]. Other research has shown that using VR and artificial intelligence enhances doctor-patient risk communication and shared decision-making in surgery [37]. Additionally, VR increases the satisfaction of patients with cancer under oncology care [38], improves therapy training knowledge [39], and reduces cancer-related symptoms (eg, anxiety, distress, and fatigue) [40,41]. Previous studies proposed the potential of AR in patient education and health literacy [42-44]. The multifaceted effectiveness of metaverse technology in different cancer-related groups implies that it may be useful for both cancer prevention and treatment.

Considering that every patient is different, and cancer care is complicated [45], developing and using an integrated metaverse service that can accomplish various aims are advantageous for meeting the needs of health professionals, patients, and caregivers as much as possible. Metaverse and cancer care research are in their early stages, and attempts to apply this emerging technology to cancer care are currently underway. An increasing number of studies [40,46] have demonstrated that metaverse technologies are promising in cancer care. However, these studies are not yet abundant and have been conducted on a small scale, often on single-purpose platforms. It is necessary to deal with a multipurpose platform not only to meet various needs associated with cancer care but also to understand the impact of metaverse on cancer care. To the best of our knowledge, no embodied integrated metaverse cancer care platform that embraces multiple purposes has been developed with combined functions and used in diverse real-world contexts. The challenges of the metaverse, such as inadequate funding, the necessity of careful effort to secure privacy, and an insufficient degree of portraying reality [47-49], may hinder large-scale continuous research. However, it is difficult to explain the authentic potential of metaverse technologies in cancer care simply by listing successful cases on a single platform.

Thus, this paper presents the initial phase of designing and creating a multipurpose metaverse cancer care platform that can be used and maintained steadily in the real world and investigates its usability. As this is the first study to use this new metaverse platform, there are several obstacles (eg, trial and error in developing and using the new metaverse platform, the need for training in platform management, and expensive initial setting cost) in securing many participants. Therefore, the usability test of this new platform is conducted in the form of a basic-level pilot test. Although the usability test recruits a smaller number of participants compared to previous studies and is at a basic level, mentioning the outcomes of the usability test along with the platform development information notably demonstrates the potential of the platform. In addition, despite these limitations, this study has its significance for disseminating and implementing the newly developed multidomain metaverse platform to multiple sites through a national-level project, thus laying the groundwork for large-scale research. We propose that metaverse technology may be well suited to building successful cancer care services. We expect the findings of this study to provide future directions for advancing integrated cancer care platforms.

Methods

Study Design

After demonstrating our cancer care platform to the users, we conducted a multicenter cross-sectional survey to examine their experiences with it.

Procedure

Metaverse Platform Development (Dr. Meta)

Dr. Meta, a metaverse technology-based digital platform for cancer care, was developed at the National Cancer Center (NCC), Korea, in October 2021. It is an XR platform that combines VR and AR elements. The main purpose of its development was to overcome physical constraints (eg, time and space) and educate health professionals (eg, doctors, nurses, and pharmacists) with additional engagement and support in providing good-quality health care services to patients. The metaverse platform development project was supported by the Ministry of Science and ICT of Korea in May 2021 to foster domestic digital health care technology and promote local, non–face-to-face digital content.

Dr. Meta was developed by considering 4 types of metaverses (virtual worlds, mirror worlds, AR, and lifelogging) and their characteristics, as suggested by the Accelerated Studies Foundation [50]. First, virtual worlds are defined as alternative worlds that are similar to or completely different from the reality created by digital data. Users can access avatars whose characteristics are projected, interact with other avatars or virtual objects, and become immersed in virtual space [17,50]. This metaverse platform offers a new virtual space that is unavailable in the real world. It allows users to create their own avatars, select virtual stages or backgrounds, perform activities, and interact with virtual objects (such as 3D organs, medical devices, animals, and plants).

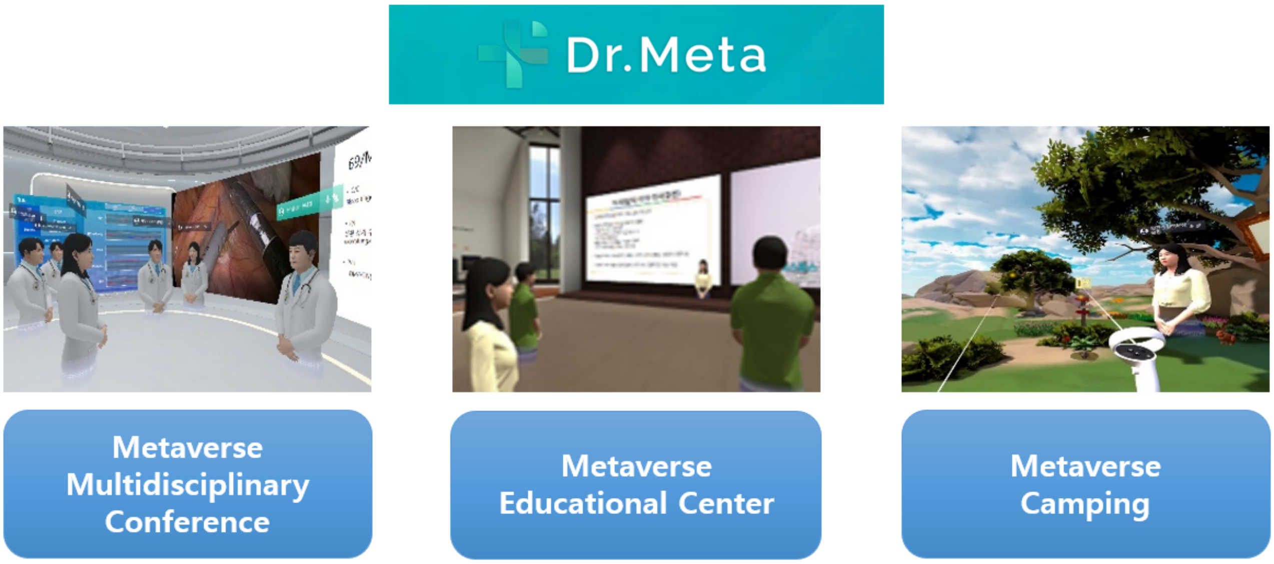
Second, mirror worlds are informationally enhanced worlds created by reproducing the real world. Virtual mapping, modeling, geospatial and other sensors, and lifelogging (history recording) technologies have been used to reflect real-world information as realistically as possible [17,50]. This metaverse platform contains several virtual backgrounds developed by replicating actual conference rooms at NCC Korea. This also includes real-time voice communication. These components may play a role in reflecting real-world environments.

Third, AR offers an interactive world created by overlapping virtual 2D or 3D objects in real space. Location-aware systems and networked information have been used to overlay virtual images with pictures or backgrounds of reality recognized by humans [17,50]. In this metaverse platform, users can upload, arrange, and display virtual objects (both 2D and 3D), actual files (eg, presentations, video clips, and images), and other resources. This exhibiting function may lead to an advanced combination of the real and virtual worlds.

Finally, lifelogging materializes in the digital world by recording, storing, and sharing everyday experiences and information about people and objects. Capturing memory, observation, communication, and behavior modeling with augmentation technologies are used to handle ordinary information [17,50]. This metaverse platform can provide patient charts and computed tomography scan images and has access to web services, including YouTube, Instagram, and other social network services in the virtual space. Users can upload photos and interact with others through voice conversation. They can assess their real-world experiences and information without time and spatial constraints and share them with others. Overall, the characteristics of all 4 types of metaverse were incorporated into the metaverse platform.

Several targeted subplatforms have been developed and operated within large platforms to achieve multidimensional goals. The metaverse platform consists of three subplatforms: (1) Metaverse Multidisciplinary Conference, (2) Metaverse Educational Center, and (3) Metaverse Camping. Metaverse Multidisciplinary Conference allows multiple health professionals from various medical fields and regions to remotely cooperate in real time by accessing the virtual space as avatars and using the 3D medical object data, patient information (eg, electronic medical record), and audio-visual data linked to the program. In Metaverse Educational Center, health professionals from other regions and medical institutions can access the virtual space of this subplatform as avatars to gain theoretical education and experience interactive medical training content. In Metaverse Camping, patients and their family members can use the XR technology in the virtual space with their relatives and acquaintances who live afar to hang out and experience psychological comfort and social support. Figure 1 shows the images of each subplatform of the metaverse platform.

Figure 1. Pictures of each subplatform of Dr. Meta.



As each subplatform has different purposes and targets, its characteristics and functions will inevitably be differentiated to optimize goal achievement. The Metaverse Multidisciplinary Conference and Metaverse Educational Center were developed to assist health professionals in efficient cooperation in real time and aid remote medical training for multiple people. The former tends to be more sensitive to privacy protection and security than the latter. The former focuses on patient treatment and is more likely to handle a patient's personal health records and private information, whereas the latter focuses on knowledge instruction and skill delivery to the audience and is less likely to request sensitive personal data. Nevertheless, health professionals primarily operate these 2 subplatforms. Fundamental activities include sharing information, communicating with other users, and interacting with digital objects. Group-level performance is primarily conducted for collaboration and education, and multiple data formats are used to achieve efficient outcomes. The characteristics of all 4 types of metaverses were found on both subplatforms.

Metaverse Camping was developed to help patients and caregivers feel comfortable and supported and is mostly operated by them, even if doctors join and communicate through it. As feelings of comfort and support occur at the individual level, the functions that focus on individual-level performance or achievement predominantly comprise Metaverse Camping. There is a plan to upgrade this subplatform considering the comfort and support that can be obtained at the social level; nevertheless, at this stage, the emphasis is on individual units. Users can interact with virtual objects and perform actions such as drawing or turning on music in a virtual campsite. Virtual-world characteristics were detected on this subplatform.

After developing the metaverse platform, we disseminated it to 6 (ie, Chonnam National University Hwasun Hospital, Gyeongsang National University Hospital, Jeju National University Hospital, Kangwon National University Hospital, Kyungpook National University Chilgok Hospital, and Pusan National University Hospital) out of 12 regional cancer centers (RCCs). We also support the arrangement of the relevant infrastructure and staff training for its installation and management.

Study Participants

After preparing Dr. Meta's operations, platform demonstrations and usability tests were conducted at 7 cancer centers. Participants aged greater than 19 years were recruited from each cancer center between November and December 2021. Before participating in the survey, participants were requested to read the research information and provide their consent. They could participate in the survey only if they consented voluntarily to do so. Participant inclusion criteria for the study were being aged greater than 19 years and having experience using 1 of 3 subplatforms of this metaverse platform. Participant exclusion criteria for the study were having experience using this metaverse platform but being aged less than or equal to 19 years, being unable to complete self-reported surveys, having a serious physical or mental condition that prevents them from participating in the study, not consenting to the survey, or withdrawing consent during the study. A daily necessity worth about $5 was provided as compensation for participating in the study. We did not ask for information that could identify participants (eg, name and social security number), so the data used in this study was deidentified. Figure 2 shows the participants who used the metaverse platform.

Figure 2. Pictures of participants using Dr. Meta.

Measures

During the survey preparation, we asked for feedback about the initially prepared questionnaire from the platform users. We received their opinions expressing a desire to avoid feeling burdened when participating in the survey after experiencing new metaverse technology. Therefore, we used a simple and concise questionnaire to ensure that participants from various groups, including patients, could easily understand it. Researchers could universally use this questionnaire to evaluate participants' experience using the metaverse platform across different subplatforms. The questionnaire first asked about participants' sociodemographic information (eg, age, sex, and position in the hospital, including patients and caregivers) to assess their characteristics. The next part of the questionnaire consisted of multiple questions evaluating participants' user experience of the metaverse platform. The questions were adapted from previous studies examining potential variables associated with using the metaverse (eg, TAM-based factors) [29,30,34], translated into Korean, abbreviated, and modified to suit the purpose and context of the study. These questions were categorized into individual differences (2 items: "I am usually interested in using new technologies or devices" and "I tend to not experience dizziness or motion sickness easily"), user satisfaction (4 items: "I was generally satisfied with using this XR platform," "This XR platform made me feel interested and immersed," "There was no discomfort (eg, dizziness and nausea) in using this XR platform," and "There was no difficulty in wearing and operating this XR platform device (ie, head-mounted display and controllers)"), and future expectations (3 items: "This XR platform will be helpful for non-face-to-face and noncontact services," "I want to continue using this XR platform in the future," and "I want to recommend this XR platform to others") relevant to the use of Dr. Meta. Each of them was scored on a 5-point Likert scale (1="strongly disagree" to 5="strongly agree"). The final part of the questionnaire consisted of an open-ended question assessing the participants' subjective opinions (ie, suggestions and improvements) about the platform. We used these 9 items and 1 open-ended question to evaluate participants' experiences with the metaverse platform. The questionnaire used in this study is shown in Multimedia Appendix 1.

Statistical Analysis

We conducted a descriptive analysis to examine how participants perceived their experiences using Dr. Meta. This user experience was rated by obtaining the frequency and proportion of participants with positive opinions for each item. The number of participants with positive opinions after using the metaverse platform was calculated by adding those who answered "agree" and "strongly agree." SPSS (version 22.0; IBM Corp) was used for the data analysis.

Ethics Approval

This study was approved by the institutional review board of the NCC Korea and the 6 RCCs (IRB NCC: NCC2021-0331; Chonnam National University Hwasun Hospital: CNUHH-2021-218; Gyeongsang National University Hospital: GNUH2021-11-012-001; Jeju National University Hospital: JEJUNUH2021-10-017; Kangwon National University Hospital: KNUH-A-2021-11-014-001; Kyungpook National University Chilgok Hospital: KNUCH2021-11-032-001; and Pusan National University Hospital: 2111-016-109).

Results

Participant Characteristics

Overall, 74 people participated in the survey after using the metaverse platform, and this study analyzed the data from 70 participants. Of the 70 participants, 3 (4%), 19 (27%), 29 (41%), 15 (21%), and 4 (6%) were aged 20-29, 30-39, 40-49, 50-59, and 60-69 years, respectively. In addition, 19 (27%) participants were male, and 51 (73%) were female. More than half (n=45, 64%) of the participants were health professionals. Table 1 presents the participants' demographic information.

Table 1. Demographic information of the participants.

Characteristics	Total (N=70), n (%)[a]	Metaverse Multidisciplinary Conference (n=15), n (%)	Metaverse Educational Center (n=35), n (%)	Metaverse Camping (n=20), n (%)
Age group (years)				
20-29	3 (4)	0 (0)	2 (6)	1 (5)
30-39	19 (27)	3 (20)	11 (31)	5 (25)
40-49	29 (41)	7 (47)	15 (43)	7 (35)
50-59	15 (21)	4 (27)	7 (20)	4 (20)
60-69	4 (6)	1 (7)	0 (0)	3 (15)
Sex				
Male	19 (27)	9 (60)	6 (17)	4 (20)
Female	51 (73)	6 (40)	29 (83)	16 (80)
Position in the hospital				
Health professionals[b]	45 (64)	14 (93)	29 (83)	2 (10)
Patients	8 (11)	0 (0)	0 (0)	8 (40)
Caregivers	9 (13)	0 (0)	0 (0)	9 (45)
Others[c]	8 (11)	1 (7)	6 (17)	1 (5)

[a]Percentages may not add up to 100% due to rounding.

[b]"Health professionals" includes doctors, nurses, and pharmacists in this study.

[c]"Others" includes hospital administrative staff, educators, social workers, and researchers in this study.

Usability Results

Regarding user satisfaction, this study's results showed that more than half (37/70, 54%) of the participants were satisfied with using Dr. Meta. In total, 50 (72%) participants responded that Dr. Meta is an interesting and immersive platform. Regarding future expectations, over half (n=50, 72%) of the participants reported that the platform would be helpful for non–face-to-face and noncontact services. Furthermore, 41 (59%) participants wanted to continue using the platform in the future, and 42 (60%) wanted to recommend it to others. Table 2 summarizes the overall positive experiences of the metaverse platform's participants.

Moreover, regarding the feedback about the metaverse platform, participants responded to the open-ended question "If you have any suggestions or improvements, please write them in." The most commonly reported one was the difficulty in wearing and operating the XR devices (eg, "The device was heavier than I thought, and wearing it was inconvenient. It was also challenging to operate the platform"; "The device is heavy; thus, it strains my neck and shoulders"; and "People wearing glasses are uncomfortable wearing the device"). Many participants also proposed that it is crucial to improve the quality of content and create realistic materials on various topics to decrease dizziness and increase immersion (eg, "If the virtual space is more realistic, I will be more immersed."). In contrast, the usefulness of metaverse platform in medical education was a representative advantage that the participants mentioned (eg, "It will be very helpful to the community medical field."). Textbox 1 presents more information about the feedback on the participants' experiences with the metaverse platform.

Table 2. The positive experience of the participants after using Dr. Meta.

Items[a]	Total (N=70), n (%)[b]	Metaverse Multidisciplinary Conference (n=15), n (%)	Metaverse Educational Center (n=35), n (%)	Metaverse Camping (n=20), n (%)
Individual differences				
I am usually interested in using new technologies or devices.	43 (62)	13 (87)	20 (57)	10 (50)
I tend to not experience dizziness or motion sickness easily.	24 (34)	3 (20)	11 (31)	10 (50)
User satisfaction				
I was generally satisfied with using this XR[c] platform.	37 (54)	10 (67)	19 (54)	8 (40)
This XR platform made me feel interested and immersed.	50 (72)	13 (87)	26 (74)	11 (55)
There was no discomfort (eg, dizziness and nausea) in using this XR platform.	34 (49)	7 (47)	16 (46)	11 (55)
There was no difficulty in wearing and operating this XR platform device (ie, head-mounted display and controllers).	30 (43)	4 (27)	15 (43)	11 (55)
Future expectations				
This XR platform will be helpful for non-face-to-face and noncontact services.	50 (72)	11 (73)	23 (66)	16 (80)
I want to continue using this XR platform in the future.	41 (59)	11 (73)	17 (49)	13 (65)
I want to recommend this XR platform to others.	42 (60)	11 (73)	18 (51)	13 (65)

[a]Items are based on a 5-point scale (1="strongly disagree" to 5="strongly agree"). The number of participants who had positive opinions after using Dr. Meta was calculated by adding the number of participants who answered "agree" and "strongly agree."

[b]Percentages may not add up to 100% due to rounding.

[c]XR: extended reality.

Textbox 1. The details of feedback on the participants' experience of Dr. Meta.

Advantages

- "It will be very helpful to the community medical field."
- "It was amazing, and I am glad my parent liked it."
- "There was nothing particularly bad about it, and seeing virtual objects in front of me was nice. Also, it was nice to experience healing for a while."
- "It could be useful if the convenience of using the device is improved."
- "Depending on how you use it, it could be helpful."
- "It was great to experience an exciting and immersive new educational system."
- "It is livelier and engaging than face-to-face or previous online training. If the content is well-developed, it can be very effective."
- "If improvements are made to induce interest and overcome physical constraints, this program will be a great way to deliver non-face-to-face education."

Improvements

- "The device was heavier than I thought, and wearing it was inconvenient. It was also challenging to operate the platform."
- "The device is heavy; thus, it strains my neck and shoulders."
- "People wearing glasses feel uncomfortable wearing the device."
- "If the virtual space is more realistic, I will be more immersed."
- "It would be nice to have a variety of content to experience. I was getting bored with the simplicity over time."
- "It was hard to use, and the voice function needed to be fixed."
- "It was inconvenient to wear and use the device. Adding a function that allows users to experience content without the device would be wonderful."
- "I need some guidance on how to operate it."
- "The device is heavy and requires time to get used to the operation."
- "The content should be designed considering different age groups and health conditions."
- "I am worried about contamination problems when multiple people share the device."
- "I wonder if applying this platform in the medical field is realistic because of the expensive cost of the device."

Discussion

Principal Findings

This study aimed to (1) develop an integrated metaverse cancer care platform and (2) examine its user experience. Dr. Meta is a multipurpose metaverse health care platform distributed and used by the local community. To the best of our knowledge, it is not only the first to be developed in South Korea but is also a unique case worldwide. This was possible because this study used a cancer center system established at the national level. Our results showed that more than half of users thought this metaverse platform was satisfying, interesting, and immersive. Although less than half of users indicated positive opinions on no discomfort in using this platform and no difficulty in wearing and operating its device, more than half of users thought it was helpful for non–face-to-face and noncontact services and wanted to use it continuously and recommend it to others. These outcomes were also observed in the pattern of responses to a feedback question. Users primarily mentioned the difficulty in wearing and operating this platform's device. They also raised the necessity of improving the quality of its content. On the other hand, users were favorable about the platform's usefulness as a medical education tool. The metaverse platform will serve as evidence to enable the expansion of the country's medical metaverse project, helping to establish a concrete direction for future research and development. It will also assist in overcoming physical constraints and proceeding with successful non–face-to-face cancer care, positively contributing to solving unequal issues of medical resource accessibility between areas (urban, metro, and rural regions).

Moreover, the findings of this study showed that various groups can use this metaverse platform according to their requirements. When it comes to the subplatforms targeting health professionals, more than half of users thought Metaverse Multidisciplinary Conference and Metaverse Educational Center were satisfying, interesting, and immersive. Even though less than half of users provided positive opinions on no discomfort in using these subplatforms and no difficulty in wearing and operating their device, more than half of users thought these subplatforms were helpful for non–face-to-face and noncontact services and wanted to recommend them to others. Over half of the users wanted to use Metaverse Multidisciplinary Conference continuously but not Metaverse Educational Center. Although the initial cost for the development of metaverse platform was relatively high, health professionals could learn repeatedly at no additional cost once the platform was deployed. Based on the results of other studies using a medical metaverse for health professionals' education

[51-53], it is feasible to predict that this platform will be more effective in providing education that cannot be easily implemented in the real world. It can also serve as a catalyst to activate the training of health professionals by enabling education on invasive treatment [54]. To maximize these advantages, a capability that the virtual world can accurately reflect the real world is needed [55,56]. This metaverse platform can be developed in the future to embody digital twins for this purpose. This should be accomplished through discussions on data sharing and privacy issues.

With respect to the subplatform targeting patients and caregivers, while less than half of users thought Metaverse Camping was satisfying, more than half of users thought it was interesting and immersive. Unlike the other 2 subplatforms, this subplatform received positive opinions on no discomfort in using it and no difficulty in wearing and operating its device from over half of users. In addition, more than half of users thought it was helpful for non–face-to-face and noncontact services and wanted to use it continuously and recommend it to others. Through this subplatform, patients can overcome physical constraints and receive support such as high-quality cancer education, monitoring, and counseling. Consequently, they can enhance self-efficacy regarding health behaviors and gain comfort, similar to other studies [57-59] examining the role of the medical metaverse in patient support. A more immersive environment may provide a greater patient experience without being disturbed by external stimuli [55,60-62]. This metaverse platform can be developed in the future to establish an immersive environment for this purpose. Additional solutions that maximize immersion should be developed, such as preparing more accessories to overcome the inconvenience of wearing such devices.

Furthermore, Dr. Meta provided evidence of a metaverse platform for conducting more sophisticated research. It can act as a stimulus in new studies that test the associations among relevant variables. Verifying the determinants or constructing predictive models using this metaverse platform could be directions for future research. For example, examining the role of immersion in the satisfaction and continuous use of metaverse platform could be an important research topic. These outcomes can guide the theory-driven development of other metaverse health care platforms for different disease contexts.

Future Perspective

The study results prove that metaverse platform has the potential to provide effective cancer care and simultaneously show that it needs to be upgraded to enhance the user experience. Some interesting differences among the subplatforms suggest that certain components of metaverse platform require further improvement. This study's outcomes showed that less than half of the Metaverse Educational Center users wanted to continuously use the Metaverse Educational Center. In addition, less than half of Metaverse Camping users responded that they were satisfied with using Metaverse Camping. We plan to set different future directions to improve subplatforms by accommodating their own purposes.

Regarding Metaverse Educational Center, an interactive environment where users can directly control and interact with virtual objects and spatial elements may allow them to become more engaged with the platform [60-62]. Such improved engagement may help users achieve their goal of sharing information successfully. For example, diverse interactive functions such as performing physical activities through motion recognition, assembling and disassembling 3D anatomical structures, and manipulating 3D medical devices may be useful for delivering messages and acquiring knowledge. These improvements are expected to be widely applicable in other health care fields. In addition to high interactivity, vivid 2D or 3D digital objects that match topics or innovative simulation functions that realistically describe topics may also strengthen users' intentions toward continuous use [63].

Concerning Metaverse Camping, gamification elements (eg, quizzes and rewards) and personalized feedback may help users successfully attain the goal of self-motivation and feeling comfortable [64,65]. This may enhance user satisfaction with the platform. For instance, if users can customize their characters, navigate campsites, complete quests, receive fruit stickers, or watch flower images appearing on trees as rewards, they may experience comfort, fun, or other positive emotions. Thus, users can dynamically interact with new virtual objects and easily immerse themselves in the platform. Among the 4 types of metaverse, these plans are closely related to virtual worlds.

Moreover, improving the voice, movement, and time spent recording functions on both subplatforms may elicit a more positive user experience. Communication within a shorter time interval in the Metaverse Educational Center or recoding the voice diary on Metaverse Camping may make users think that they are putting their daily life information on the platform and that it is tailored. As people tend to favor personalized information [66], these upgrades may encourage them to use the platform. Among the 4 metaverse types, these plans are closely related to lifelogging. In summary, we plan Dr. Meta's future development by focusing more on the virtual world and lifelogging aspects. It is expected that the influence of these improvements will not only be within the subplatform but will also positively affect the evaluation and actual use of the entire platform by stimulating user satisfaction and curiosity.

Furthermore, it is possible to present meaningful directions for future development and maintenance beyond the scope of subplatform improvement. Currently, Dr. Meta is mainly used through the head-mounted display (HMD); however, many participants complained of motion sickness due to the HMD or said that it was difficult to wear and handle. Therefore, we plan to develop different versions of the metaverse platform that can be operated on various media types, such as desktops and tablets, to reduce the dependence on HMD. We will also develop a user-friendly manual to guide the use of Dr. Meta and provide it to the users to minimize inconvenience. In addition, according to their feedback, several participants felt content needed improvement. For example, they stated that the content was monotonous and lacked realism. Thus, we will emphasize vivid and realistic depictions of content that need to be authentic and fantasy elements of content that need to be fictional. We also plan to increase the number of content scenarios and videos that users can choose. Additionally, some participants suggested that providing content that reflects user characteristics might enhance the quality of services. Therefore, in the future, we will prepare various content and matching algorithm systems to satisfy user requirements. Finally, current subplatforms and content are still insufficient to cover the complexity of cancer care. Therefore, we will gradually expand the metaverse platform by developing new subplatforms tailored to target participant groups to diversify its purposes and functions. While securing various subplatforms, we will spur Dr. Meta's operation by applying models and content well-fitted with topics.

While advancing Dr. Meta, we sought to diversify its uses. Our research is currently supported by the Ministry of Health and Welfare of Korea starting in 2022, linked to a government project that focuses on establishing infrastructure and maintaining its setting to disseminate and implement new digital health care technologies in local communities. We aimed to establish an environment in which we could cooperate with health professionals from other hospitals in multiple regions of South Korea. In addition, a platform will be developed to collaborate on education or research with Koreans as well as foreign hospitals and research institutes.

Limitations

Although there were favorable evaluations and expectations of this platform, this study had some limitations. First, the sample size seems to be small. As this was the first study conducted following the development of metaverse platform, the main focus was to explore the field applicability of the newly developed metaverse platform called Dr. Meta. Therefore, although there was a limit to securing a sufficient number of users, this study first examined the feasibility of metaverse platform by conducting a usability test in the form of a pilot test on a small number of people to provide evidence of the potential for practical use of the platform. To address this issue, we will invite new RCCs to our project and recruit participants for an extended period in future research. Dr. Meta is expected to operate more stably in the future; therefore, more participants are expected to be recruited.

Second, it looks like the proportion of participants is unbalanced by position in the hospital. The number of participants who were patients or caregivers was small, and health professionals mainly participated in the study. It is a natural occurrence because 2 of the 3 subplatforms introduced in this study were developed for health professionals, and we even wanted to test the subplatform developed for patients on health professionals first before providing it to patients to ensure safety and appropriateness. Still, it is important to have an even distribution of sufficient participants for good-quality data analysis. We will consider performing large-scale participant recruitment along with applying a statistical methodology that deals with the percentage of participants of each subgroup in the population or its representation, such as stratified sampling, to collect adequate data inclusively in future research.

Third, although presenting the metaverse platform's development information and its outcomes of usability test together shows that the platform is promising for successful cancer care, the basic level of this usability test seems difficult to deal with more elaborate research questions. For example, there was an absence of use of existing validated questionnaires in this study. This study was conducted as an early-stage pilot study, and a questionnaire developed for an exploratory purpose was used rather than a structured one. Furthermore, this study aimed to include patients among the overall participants, so we needed to consider their understanding of the questionnaire. It was decided to use a theory-based but straightforward, easy, and short questionnaire because patients typically need care and can easily get tired after experiencing new metaverse technologies and platforms. It provided flexibility and ease of conducting usability assessments in the real-world field. On the other hand, it was limited in its ability to scrutinize the relationships between variables related to user satisfaction. As this was the first study to use the metaverse platform, it was inevitable that this study focused on introducing its development in detail. Nonetheless, to verify this multidomain platform's potential, we undertook its usability test together regardless of the test level. Considering that medical metaverse research is currently in its infancy, this study may encourage scholars to go beyond the medical metaverse research centered on reviews or single-domain platform studies and practitioners to adopt a large-scale medical metaverse platform. We will design future studies that intensively investigate a target subplatform's features and content based on sufficient participants and an advanced understanding of the topic. For a sophisticated examination of the metaverse platform's user experience and influence, we will upgrade our current questionnaire by adding more theory-based simple items asking about potential other new variables related to the usability of the medical metaverse. We will also consider using a systematically validated usability questionnaire when planning a future study examining a target subplatform with a fixed participant group and topic.

Conclusions

To the best of our knowledge, this study is the first to verify the possibility of developing multidomain metaverse cancer care platforms in South Korea that have the potential for successful non–face-to-face cancer care. This study was the starting point for examining the effectiveness of this metaverse cancer care platform. We will develop the metaverse platform to strengthen user immersion and tailor experiences by highlighting virtual worlds and lifelogging. If the development of hardware devices and software content suitable for this purpose is combined, this medical metaverse platform will successfully ease the burden on patients with cancer. Moreover, the platform has been disseminated and implemented for multiple RCCs. Future developments may solve physical distance and disparities in access to medical resources more effectively. The metaverse platform will be an alternative cancer education method for health professionals against COVID-19 and will be especially helpful for patients not living in urban areas to obtain cancer care benefits. This research provides not only the development of simple medical metaverse platform functions but also an environmental model that can facilitate the sustainable use of the platform. We will progress in more extended future research with more participants to enrich evidence about the effectiveness of Dr. Meta and discover more in-depth scientific insight about this multidomain metaverse cancer care platform.

Acknowledgments

The authors thank Chonnam National University Hwasun Hospital (principal investigator [PI]: Won-Ju Park), Gyeongsang National University Hospital (PI: Ok Jae Lee), Jeju National University Hospital (PI: Chul Min Park), Kangwon National University Hospital (PI: Gibong Chae), Kyungpook National University Chilgok Hospital (PI: Seong Woo Jeon), and Pusan National University Hospital (PI: Hong Jae Jo) for their collaboration in developing Dr. Meta and conducting the usability tests. Abstract

Background: Exergames have attracted growing interest in the prevention and treatment of neurocognitive disorders. The most effective exergame and training components (ie, exercise and training variables such as frequency, intensity, duration, or volume of training and type and content of specific exergame scenarios) however remain to be established for older adults with mild neurocognitive disorders (mNCDs). Regarding the design and development of novel exergame-based training concepts, it seems of crucial importance to explicitly include the intended users' perspective by adopting an interactive and participatory design that includes end users throughout different iterative cycles of development.

Objective: This study aimed to determine the capabilities, treatment preferences, and motivators for the training of older adults with mNCD and the perspectives of individuals on training goals and settings and requirements for exergame and training components.

Methods: A qualitative study including expert focus groups and individual semistructured in-depth patient interviews was conducted. Data were transcribed to a written format to perform qualitative content analysis using QCAmap software.

Results: In total, 10 experts and health care professionals (80% females) and 8 older adults with mNCD (38% females; mean age 82.4, SD 6.2 years) were recruited until data saturation was observed.

Conclusions: The psychosocial consequences of patients' self-perceived cognitive deterioration might be more burdensome than the cognitive changes themselves. Older adults with mNCD prefer integrative forms of training (such as exergaming) and are primarily motivated by enjoyment or fun in exercising and the effectiveness of the training. Putting the synthesized perspectives of training goals, settings, and requirements for exergames and training components into context, our considerations point to opportunities for improvement in research and rehabilitation, either by adapting existing exergames to patients with mNCDs or by developing novel exergames and exergame-based training concepts specifically tailored to meet patient requirements and needs.

Introduction

Background

The normal aging process is associated with a decline in physical and cognitive abilities [1,2]. When the cognitive decline exceeds the normal age-related cognitive decline but is not severe enough to interfere with independence in activities of daily living, it can be classified as "mild cognitive impairment" (MCI), representing an intermediate stage of cognitive impairment between the normal aging process and dementia [3-9]. The condition MCI has evolved over the last decades [5] and has recently been incorporated in the latest Diagnostic and Statistical Manual of Mental Disorders 5th Edition (DSM-5) and the International Classification of Diseases 11th Revision, referred to as mild neurocognitive disorder (mNCD) [7,9-11]. The prevalence of mNCD increases with age, while the incidence of mNCD and the progression to dementia is expected to rise, largely because of the globally growing life expectancies and sedentary lifestyles [3,5,12-15]. As currently no effective pharmacological interventions for patients with mNCD exist [16], alternative options to prevent and treat neurocognitive disorders are needed. Targeting modifiable risk factors in midlife may hold promise for mitigating or even preventing neurocognitive disorders in later life [17-21]. The modifiable risk factors for mNCD include the presence of vascular risk factors (ie, metabolic syndrome, hypertension, hyperlipidemia, coronary heart disease, diabetes mellitus, or stroke) [22-24] or a physically or cognitively sedentary lifestyle [25,26]. Consequently, changes in lifestyle that increase physical and cognitive activity and reduce vascular risk factors are protective against cognitive decline [27-35].

Exergames have gained growing interest to prevent and treat neurocognitive disorders [36-38]. "Exergaming is defined as technology-driven physical activities, such as video game play, that requires participants to be physically active or exercise in order to play the game" [39]. One of the major advantages of exergame-based training is that it is widely accepted by individuals with neurocognitive disorders. In addition, it increases training adherence and engagement by facilitating training motivation and satisfaction [40], which in turn may have a positive effect on the effectiveness of improving cognitive functioning [41]. Furthermore, exergames can be used as a form of simultaneous cognitive-motor training with incorporated cognitive task demands [42]. Meta-analytic evidence suggests that simultaneous motor-cognitive training is the most effective type of training for improving cognition in healthy older adults (HOA) [43,44] and older adults with mNCD [44-46]. For exergames specifically, a recent systematic review synthesized evidence from low risk of bias studies showing that there were consistent positive effects favoring exergaming in people with mNCD and dementia [40]. Nonetheless, it is currently difficult to draw reliable conclusions about the effectiveness of exergaming in preventing and treating neurocognitive disorders because of the substantial variations in the exergame-based training used. Therefore, further investigations are needed for the establishment of effective exergame and training components (ie, exercise and training variables such as the frequency, intensity, duration, or volume of training and the type and content of specific exergame scenarios) for cognitive functioning that can be applied with confidence in evidence-based exergame interventions [36].

Regarding the design and development of novel exergames, it seems crucial to explicitly include the intended users' perspectives [47]. Taking the characteristics, needs, and experiences into account should ensure adequate use and therefore the effectiveness of the solution. Baquero et al [48] pointed out that an end user–centered methodological design is most often adopted in the development of computer-based training programs for cognitive rehabilitation of older adults with neurocognitive disorders (NCDs). In an ideal case, this process fulfills the international standards for the development of programs including (1) understanding and specifying the context of use (type, characteristics and tasks of users, and physical or social environment), (2) specifying the user requirements, (3) producing design solutions, and (4) evaluating the design [48,49]. So far, only half of the studies reporting computer-based interventions took the standard "specification of user requirements" into account [48]. This has led to the recommendation that future studies in this field should use an interactive and participatory design that explicitly includes end users throughout different iterative cycles of development [48]. In short, it is important to systematically and thoroughly investigate the specific user requirements and preferences for an exergame-based training concept before it is designed and developed.

Objectives

This study aimed to determine the capabilities, treatment preferences, and motivators for the training of older adults with mNCD and the perspectives of individuals on training goals and settings and requirements for exergame and training components.

Methods

Overview

This study is part of the national project "Brain-IT," which began in August 2020 in Switzerland. The aims of the overall project are (1) to determine the most suitable components for exergame-based training in older adults with mNCD; (2) to explore novel strategies for a real-time adaptive exergame system to individually tailor exergame demands according to users' physical or cognitive capabilities; (3) to incorporate the acquired knowledge into an exergame-based training concept with the aim of halting or reducing cognitive decline and improving quality of life; and (4) to evaluate the effectiveness of the resulting training intervention in older adults with mNCD. The project is guided by a theoretical framework that provides specific guidance in the design, development, and evaluation of exergames for older adults, the "Multidisciplinary Iterative Design of Exergames (MIDE): A Framework for Supporting the Design, Development, and Evaluation of Exergames for Health" [50], which provides specific guidance in the design, development, and evaluation of exergames for older adults. This study is part of the first phase of the project, with the aim to specify a "set of design requirements that includes design considerations, accessibility recommendations, user modeling elements, and technological reflections to be followed in the design and development phase" [47,50], and it was combined with an extensive literature review and reflections on technology scoping and sustainability strategy (see steps 4 and 5 of phase 1 of our recently published methodological paper [47]). For the project, the exergame device "Senso (Flex)" (Dividat AG) was preselected on the basis of (1) our previous research, (2) because this device has already been shown to be feasible and well-accepted in geriatric patients [51] and patients with major neurocognitive disorder [52], and (3) because it is already widely used (and therefore available more widely and for longer term by end users and health care institutions) for motor-cognitive training within geriatric populations, physiotherapies, or rehabilitation clinics in Switzerland. On this basis, this qualitative study was designed to achieve the defined objectives in general; in addition, it also aimed to collect evidence about the previous experiences of experts or health care professionals with different exergame systems [including the "Senso (Flex)"]. In this way, the project team wanted to collect evidence to make an informed decision whether the specific exergame device was suitable for the project, what possible modifications might be needed to optimize the exergame experience for patients with mNCD, and whether and what alternative exergame devices are suggested by the experts (see subsections of "(T2) Treatment Experience and Preferences—Previous Experiences with Exergames ('Senso' specifically)" and "(T5) Exergame and Training Components—Exergame System and Content" in the focus group discussions). Other than parts of these 2 sections that include device-specific findings, none of the remaining sections in this manuscript are device specific.

Study Design

A qualitative study was conducted between November 2020 and January 2021, including expert focus groups and patient interviews; both were organized as semistructured, in-depth interviews. Semistructured, in-depth interviews are the most widely used interviewing format for qualitative research and are generally organized around a set of predetermined open-ended questions, with additional questions and discussion points emerging from the dialogue [53]. The study was planned and reported in accordance with the "consolidated criteria for reporting qualitative research (COREQ)" [54].

The MIDE Framework [50] guided our approach. On the basis of this framework, we integrated multiple stakeholders into the design and development process including exergaming researchers, clinical experts with different backgrounds, a company representing the exergaming industry, and the end users.

Ethics Approval

All the study procedures were performed in accordance with the Declaration of Helsinki. The study protocol (not registered) was approved by the ETH Zürich Ethics Commission (EK 2020-N-154). All interested individuals were fully informed of the study procedures. The expected benefits and risks of the study were explained by the study investigator, who was also able to answer open questions and clarify individuals' uncertainties. It was further verified that withdrawal was permitted at any time during the study without providing any reason. After sufficient time, suitable individuals willing to participate in the study provided written informed consent and were included in the study. No compensation was provided to the participants.

Participants

Experts

Recruitment aimed at including experts and health care professionals experienced with exergame training of older adults with mNCD, preferably (but not necessarily) with the exergame training system "Senso (Flex)" or similar. For this purpose, Dividat AG was asked to provide a contact list of 10 to 15 external experts and health care professionals with a variety in age, sex, educational level, and experience in therapy of older adults with mNCD, who are not employed by Dividat AG or had received any funds from Dividat AG for their work. All recommended experts and health care professionals were contacted via email between November and December 2020. By applying broad inclusion criteria, a rich spectrum of experts and health care professionals were considered in the study, which in turn will foster the usability of the resulting program in clinical practice. The specific eligibility criteria comprised the following aspects: (1) experts or health care professionals (eg, physical therapists, movement therapists, neuropsychologists, or researchers experienced with exergames) experienced with exergame training or with older adults with mNCD; (2) German or English speaking; and (3) age ≥18 years. There were no specific exclusion criteria.

Older Adults With mNCD

Older adults with mNCD were consecutively recruited between November 2020 and January 2021 in collaboration with health care institutions and (memory) clinics in the larger area of Zürich. Leaflets and study information sheets containing researchers' contact details were handed out to suitable patients by their therapists. Suitable patients were identified from medical records and patient registries of memory clinics or from diagnostics that had just been performed. Interested patients were contacted by the research team by telephone or email to clarify or obtain further information about the study procedures and to register interest in participating in the study. Subsequently, all patients were fully informed about the study procedures in a face-to-face meeting at the patient's homes. In addition, patients of interest were screened for eligibility. The eligibility criteria are presented in Textbox 1.

Textbox 1. Description of all eligibility criteria.

- Inclusion criteria
  - Participants fulfilling all the following inclusion criteria were eligible:
    - (1= mild neurocognitive disorder [mNCD]) clinical diagnosis of "mNCD" according to International Classification of Diseases 11th Revision [7] or Diagnostic and Statistical Manual of Mental Disorders 5th Edition [9]) OR (2=sMCI). Patients "screened for MCI" according to the following criteria: (1) informant (ie, health care professional)–based suspicion of mild cognitive impairment confirmed by (2) an objective screening of mild cognitive impairment based on the German version of the using the Quick Mild Cognitive Impairment Screen [55] with (b1) a recommended cutoff score for cognitive impairment (mild cognitive impairment or dementia) of <62/100 [56], while (b2) not falling below the cutoff score for dementia (ie, <45/100 [56])
    - German speaking
- Exclusion criteria
  - The presence of any of the following criteria led to exclusion:
    - Presence of additional, clinically relevant (ie, acute or symptomatic) neurological disorders (ie, epilepsy, stroke, multiple sclerosis, Parkinson disease, brain tumors, or traumatic disorders of the nervous system)
    - Presence of any other unstable or uncontrolled diseases (eg, uncontrolled high blood pressure, progressing or terminal cancer, etc)

Procedures and Data Collection

Expert Focus Groups

The expert focus groups were moderated by the first author (PM) into groups of up to 5 experts. The moderator was a male doctoral student with a master's degree in Health Sciences and Technology (ETH Zürich, Switzerland), who was trained for qualitative research. Owing to the COVID-19 pandemic, all focus group sessions were held as web-based meetings in the form of Zoom sessions (Zoom Video Communications), took approximately 60 to 90 minutes to complete, and were audio recorded. Each session started with a short presentation of the background and overall aim of the project. Subsequently, the aim of this study was presented before starting the focus group discussions. The focus group discussions were organized as semistructured, in-depth interviews with open-ended questions to enable open conversations [53]. The exchange was conducted following a focus group guide (Multimedia Appendix 1) structured along 5 topics, each consisting of multiple key questions. First, the capabilities of older adults with mNCD were discussed, in continuation with insights into training goals and outcomes in the perspective of patients as well as therapists. Thereafter, the exchange focused on treatment experiences and preferences as well as motivators for training of older adults with mNCD. Finally, the requirements and optimal components of the exergame-based training were critically discussed. To focus the moderator's attention on participants' verbal and nonverbal communication and because handwritten notes during interviews are considered relatively unreliable, no notes were taken during the focus group sessions [57].

Patient Interviews With Older Adults With mNCD

The patient interviews were conducted individually with each patient by the first author (PM) and either took place at ETH Zürich (Institute of Human Movement Sciences and Sport, Leopold-Ruzicka-Weg 4, 8093 Zürich) or at the patients' homes, depending on the patients' preferences. The interview sessions were held face-to-face in a quiet room with no one present besides the interviewer, the patient, and, if requested, a care professional or partner as personal support for the patient. We did not set a time limit for the interviews but gave all participants enough time to share their views on the topics discussed. On average, each session took approximately 20 to 30 minutes to complete and was audio recorded. Before starting the interview, the background and overall aim of the project as well as the aim of this study were explained to each patient. The interviews were organized as semistructured, in-depth interviews along an interview guide (Multimedia Appendix 1) [53]. The interview guide was not pilot-tested, as it was developed by the first author (PM) in collaboration with the second author (MA), an experienced clinical neuropsychologist. After questioning the patients' capabilities as well as their previous treatment or training experience and preferences, the interview continued with questions about motivators for training and the preferred components of exergame-based training. Open-ended questions were asked to enable an open conversation [53]. To focus the moderator's attention on patients' verbal and nonverbal communication, no notes were taken during the interviews [57]. Finally, the interviewer was prepared to tailor the interview questions and communication style to the patients' capabilities, and in case of higher levels of impairment, to adopt strategies suggested to optimize communication with patients with NCDs [58,59].

Sample Size

The intended sample size was set at approximately 5 to 10 experts for the focus group sessions and 5 to 10 older adults with mNCD for the patient interviews; however, study participants were consecutively included until data saturation was reached [60].

Data Analysis

First, all audio files were transcribed in written format in Microsoft Word in pseudonymized form. The transcripts were not returned to the participants for corrections or comments. To explore the perspectives of patients and experts or health care professionals, a qualitative content analysis was performed according to Mayring et al [61,62] using QCAmap software [62-64]. The first step in the analysis involved repeated readings of the transcripts and listening to the original audio files to gain a better understanding of the conversation content. Second, the type of analysis (ie, category assignment procedure) was predefined for each of the research questions (ie, key questions of the interview guide). In case of an inductive category assignment procedure, a selection criterion and level of abstraction were defined for each of the research questions. For deductive category assignments, each research question was operationalized into categories, and a corresponding coding guideline (ie, category label, category definition, anchor example, and coding rules) was formulated. On the basis of this, all transcripts were coded line-by-line (ie, including a revision of the category system after a pilot loop). Subsequently, each resulting list of categories was grouped into main categories, and inter- and intra-agreement checks were performed. Finally, the results of each key question were analyzed along the structure (including predetermined themes and topics) of the interview guide that was created according to the guidelines of the MIDE Framework [50]. Thus, the results were structured and analyzed in 2 main themes and 5 topics. First, the section "user modeling" that included 3 topics: (T1) capabilities of older adults with mNCD, (T2) treatment experiences and preferences, and (T3) motivators for training. Second, "therapeutic needs," including (T4) training goals and outcomes and (T5) exergame and training components. Within the topic "(T1) capabilities of older adults with mNCD," the described cognitive capabilities and difficulties were classified into the key neurocognitive domains (as defined by Sachdev et al [10]) in line with DSM-V [9] on agreement between the first (PM) and second author (MA; an experienced neuropsychologist). Within the topic "(T3) motivators for training," the motivators for training were coded and analyzed against the background of the "Self-determination Theory" [65]. The Self-determination Theory [65] accounts for the quality of different levels of motivational regulation in physical activity settings. It is considered useful to gain a better understanding and promote training motivation, enjoyment, and adherence and has demonstrated considerable efficacy in explaining exercise motivation and behavior [66-70]. Data from the qualitative content analysis were combined with quantitative data (ie, frequency of various statements [f] and in the case of patient interviews, the proportion of patients making a statement [in %]) [60]. The coding and data analysis process was cross-checked to enhance the credibility of the analytic procedure [60].

Results

Participants

In total, 11 external experts and health care professionals were contacted by the first author (PM). All experts responded and were interested in participating. Two experts could not participate in the focus group sessions because of time constraints. According to the "integrative" contribution of the MIDE Framework, "perspectives of various stakeholders (*e.g.*, industry partners, data analysts, health care professionals) are considered in the process of designing and developing exergames*"* [50]. In accordance with this, the founder of Dividat AG was involved in one of the focus group discussions as an industry representative. In total, 10 experts and health care professionals (80% females) participated in 1 of the 5 focus group sessions until data saturation was observed and further recruitment was terminated. The focus group sessions were conducted in groups of between 1 (*k*=3) and 3 (*k*=1) experts (median 1.5) and the moderator (PM). The professional backgrounds of the experts and health care professionals included exergaming researchers (n=4), physical and occupational therapists (n=2), neuropsychologists (n=2), project manager therapy (n=1), and founder of an exergaming company (n=1).

For the patient interviews, 8 patients (38% females; mean age 82.4, SD 6.2 years; mean level of cognitive functioning, measured by the German Version of the Quick Mild Cognitive Impairment Screen [55], 56.0, SD 8.2) were invited and interviewed until data saturation was observed and further recruitment was terminated. None of the patients refused to participate or dropped out of the study after providing their written informed consent. The demographic characteristics of the patients are summarized in Table 1.

Table 1. Demographic characteristics of the study population.

	Total sample (n=8)
Age (years), mean (SD)	82.4 (6.2)
BMI (kg/m^2), mean (SD)	23.1 (2.4)
Physical activity (min/week), mean (SD)	298.8 (227.0)
Qmci[a] [55] total score (points), mean (SD)	56.0 (8.2)
Clinical subtype, n (%)	
mNCD[b] due to Alzheimer disease	6 (75)
Mild frontotemporal NCD[c]	0 (0)
mNCD with Lewy bodies	0 (0)
Mild vascular NCD	2 (25)

[a]Qmci: Quick Mild Cognitive Impairment Screen.
[b]mNCD: mild neurocognitive disorder.
[c]NCD: neurocognitive disorder.

Qualitative Content Analysis Results

T1: Capabilities

The experts described a large variety of impairments observed in older adults with mNCD. The most frequently described impairments referred to cognitive functioning (f=43), including impairments in the following neurocognitive domains: executive function (f=23), complex attention (f=11), learning and memory (f=7), visuospatial skills (f=2), language (f=1), and social cognition (f=1). These cognitive changes were also described as affecting psychosocial factors (f=22), mainly by causing psychological distress (f=9) and feelings of insecurity (f=2), leading patients to try to hide their impairments from others (f=2). In addition, an increased fall risk (f=9) and reduced physical resilience (f=7) were observed. Although experiencing difficulties in activities of daily living (ADLs; f=1), patients were described as maintaining their functional independence in ADL (f=2).

In line with the experts' viewpoint, cognitive deterioration (f=22, n=7, 88%) was frequently described by the patients, mainly affecting learning and memory (f=11, n=4, 50% of patients), executive function (f=6, n=4, 50% of patients), and complex attention (f=5, n=2, 25% of patients), whereas only minor restrictions in physical capabilities and mobility were mentioned (ie, impaired balance, [f=2, n=2, 25% of patients], reduced gait speed [f=1, n=1, 13% of patients], increased fall risk [f=9, n=5, 63% of patients], fatigue [f=6, n=3, 38% of patients], and joint pain [f=2, n=2, 25% of patients]). ADLs remained preserved in all patients, but the need for coping strategies was mentioned by 4 patients (50%) to be able to preserve ADLs. From the patients' perspective, the consequences of their self-perceived subjective cognitive decline (f=8, n=6, 75% of patients) with regard to psychosocial factors were most frequently reported (f=36, n=8, 100% of patients), mainly involving psychological distress (f=13, n=2, 25%), feelings of insecurity (f=6, n=3, 38% of patients), depressive symptoms (f=2, n=2, 25% of patients), or fear of repeated falls (f=3, n=1, 13% of patients):

> *A really tedious thing is that you often can't keep up. For example, in discussions or conversations. [...] You often think about what the other(s) have just said and in the meantime he or she has already continued. That's why you often just don't say anything. Of course, most people like it when you don't say anything (*laughs*). So, these people don't get upset about it. But I am.* [P-01]

> *I used to go running a lot. I don't do that anymore. But swimming is still fine. In the worst case, I become a drowned corpse, but at least I can't fall while swimming.* [P-02]

> *I can actually do everything; I just have to be careful because of my dizziness and weakness so that I don't fall. I also have problems with short-term memory. I have to try to remember everything somehow, but I still forget a lot of things.* [P-04]

T2: Treatment Experience and Preferences

Previous Treatment and Training Experiences

To counteract cognitive decline and preserve physical capabilities, mobility, and ADLs, patients have already been on medical training therapy (MTT; f=3, n=3, 38% of patients), have already been on physical therapy (PT; f=2, n=2, 25% of patients), have performed a specific group-based (ie, f=1, n=1, 13% of patients) or individual (f=1, n=1, 13% of patients) cognitive training or meditation (f=1, n=1, 13% of patients), or have reported to have no experience in any specific therapy or training (f=1, n=1, 13% of patients).

From the patient's viewpoint, MTT and PT were perceived as useful (f=3, n=3, 38% of patients), but patients reported that they would have to do it more consistently to profit from it (f=2, n=2, 25% of patients). Computerized cognitive training (CCT) was also perceived as useful (f=1, n=1, 13% of patients) and reported to be challenging, fun, and enjoyable (f=2, n=2, 25% of patients). Nonetheless, patients reported being insecure about the effectiveness of CCT (f=2, n=2, 25% of patients):

> *[In response to PT] [...]my gait has improved. I now take slow and long steps and no longer fall over. However, I would definitely have to do it more consistently.* [P-02]

> *The problem is primarily that my physical therapist only has time for me every 14 days because she is so booked up. Of course, it would be nice if I could go more often. But it is what it is, and I have to live with it.* [P-08]

> *[Patient explains game tasks of CCT] It's not even that simple. This is all fun and useful. But I don't know if it will do any good. [and] I have no intention of stopping. However, at some point I have to ask myself: "Does is go any further? Or is it just going to stay at what I'm currently able to manage?"* [P-01]

According to the experience of experts and health care professionals, only cognitive forms of training or physical exercises were often experienced as boring over time by older adults with mNCD (f=2) and required guidance by a therapist (f=2). More integrative forms of training, including gamified tasks close to everyday life, multimodal animation, and acoustic feedback, were reported to be preferred by patients (f=4):

> *It is often the case that patients are completely dependent during strength training, [and] [...]they just kept on exercising and exercising. [...] They often continue the exercises until you stop them.* [E-10: founder of an exergaming company]

> *Cognitive exercises including "a certain closeness to everyday life and also a multimodal animation[...] and acoustic feedback have been very well received."* [E-03: neuropsychologist]

Previous Experiences With Novel Technologies

Although being described as skeptical about the use of technological devices, experts perceived older adults with mNCD as ready to use technological devices such as heart rate monitors during training (f=9), if its usability is ensured:

> *Well I think using a sensor it's not a problem if the wearable is well designed.* [E-01: exergaming researcher]

> *Many people would certainly be okay with a Polar chest strap, but a monitor to be worn at the wrist would certainly be preferable. If people are told why these sensors are used and what they are measuring, it should be feasible with the chest sensors as well. It may be difficult with certain older ladies or overweight individuals, but for the average individual this should not be a problem.* [E-03: neuropsychologist]

The experts' perceptions coincided with those of patients. All patients were willing to use a heart rate monitor worn with a chest strap during training, provided it was beneficial for their training. In addition, 75% (6/8) of patients stated that their PC or television was usable, whereas 25% (2/8) of patients reported limited usability:

> *[Regarding the use of heart rate monitors during training] [...]provided it's useful I would be ready to wear such a heart rate monitor without having any reservations at all.* [P-01]

> *[About the usability of the television] Sure! All you have to do is press the switch. That's still possible.* [P-07]

> *[About the usability of the personal computer] Yes, using my personal computer works more or less. [...] It is just not something of my generation. I have a computer and I use it, but there are always things I can't do and have to ask my granddaughter.* [P-01]

Previous Experiences With Exergames ["Senso (Flex)" Specifically]

None of the interviewed patients reported any previous experience with exergames in general or with the exergaming system "Senso (Flex)" specifically. Nonetheless, after a short introduction to the system, all patients stated that they would be willing to try it.

On the basis of the previous experiences of the experts and health care professionals, the interaction with the "Senso," its overall usability, and the design of the exergames have been described as good (f=5). Regarding hardware components, minor usability problems have been reported. Patients were observed to unintentionally walk off the middle plate without noticing the feedback on the screen (f=4), constantly change their focus between the game tasks on the screen and the stepping plate to anticipate and plan their movements (f=4), or make too small steps to tap on one of the outer stepping plates (f=1). In addition, the patients needed time to familiarize themselves with the sensitivity of the stepping plate (f=2):

> *[...]the "Senso" is in general well usable and is also very often used.* [E-04: exergaming researcher]

> *The tasks on the "Senso" are very well designed.* [E-08: project manager therapy]

> *[...]the "Senso" is already very user friendly, [but] I had a little problem at the beginning of the experiment where people would accidentally go out of the square in the middle of the "Senso".* [E-09: exergaming researcher]

> *Most of the time, the patients look down at that very moment and thus do not see the message [on the screen] at all.* [E-07: physical and occupational therapist]

Additional usability issues were reported to be linked to the capabilities of older adults with mNCD. First, it has been described that patients are often cognitively overloaded when trying out new games (f=1), by the occurrence of an unexpected situation or technical errors (f=2), or by the cognitive task demands required to interact with the exergame system in general (f=1), which may limit training duration owing to attentional exhaustion (f=2):

> *With new games, patients are often overwhelmed in general, because they don't know what to expect.*

> *They often need time to find their way around.* [E-07: physical and occupational therapist]
>
> *[...] Patients are completely overwhelmed as soon as something unexpected or a technical problem occurs.* [E-03: neuropsychologist]

In contrast, the physical capabilities were reported to not directly affect the usability of the system (f=4), although some patients experienced difficulties with backward steps (f=2), and many patients made use of the handrail to reduce the physical strain (f=6). In some cases, physical limitations (eg, fatigue and joint pain) resulting from static loading have been reported to limit the training duration (f=4):

> *Patients often have problems with backward steps. [and] Patients hold on to the handrail far too often. [...] it is often the case that people hold on because it is simply 'a bit more comfortable.* [E-10: founder of an exergaming company]
>
> *Often it is already difficult and tiring for patients to stand for a longer period of time. It is often easier for them to walk. [and] However, it should be noted that this form of fatigue is not necessarily comparable to fatigue caused by physical training. Fatigue does not necessarily come from physical exertion. It is possible that this type of fatigue is caused by the static load and the resulting joint pain.* [E-06: physical and occupational therapist]

When considering the specific games of the exergaming device "Senso" (video illustrations and explanations of all currently available games can be found at [71]), the simple and clear design structures of the games (f=4) and the intuitive tasks were reported to be highly appreciated by patients and promote good comprehensibility, which was reported for the games "Simple" (f=3), "Birds" (f=3). Nonetheless, there are also games that were reported to cause problems of understanding, in particular the games "Simon" (f=3), "Tetris" (f=3), "Habitats" (f=4), "Targets" (f=1), and "Snake" (f=2). These problems may be related to the game instructions (f=9):

> *[...]Many people are very happy with simple design structures. This should be maintained at all costs when designing new games for MCI patients. However, [...]some kind of adjustment of the game instructions is definitely needed.* [E-10: founder of an exergaming company]
>
> *For patients, a game does not stand out by its great graphics, but by the game tasks as such.* [E-08: project manager therapy]
>
> *[About problems of understanding the games] I think the reasons were that they didn't really understand the instructions well.* [E-09: exergaming researcher]

However, it could also be related to the task demands of the games. It was reported that the patients need some time to familiarize themselves with the game to fully understand it (f=1). According to the experts' experiences, this works well with the games "Simple" (f=4), "Birds" (f=1), "Flexi" (f=1), and in some cases "Habitats" (f=1). At the same time, games such as "Flexi" (f=1), "Habitats" (f=6), "Hexagon" (f=3), "Simon" (f=6), "Ski" (f=4), "Targets" (f=12), and "Tetris" (f=4) were frequently reported to start at an already (too) challenging level for older adults with mNCD and progress too fast while there is a limited range of games or adaptability of task demands at the lower end of difficulty levels (f=9). This was mentioned to be mainly apparent for the cognitive task demands (eg, game speed and task complexity), whereas physical exercise intensity is often (too) low and could be increased (f=4):

> *For MCI-patients, some games are predestined to be used with them, such as "Simple," "Flexi," "Birds" and perhaps also "Habitats." These games don't put so much time pressure and the feeling of having missed something on patients.* [E-08: project manager therapy]
>
> *[...]the increase in the challenge profile from the easiest games ("Simple" and "Birds") to the next more difficult game is too steep for MCI-patients. For example, the game "Targets" is too fast for many patients. The game "Habitats" contains too many stimuli at once, so that the patients no longer know what they have to pay attention to.* [E-07: physical and occupational therapist]
>
> *[...]I have the impression that the internal progression, which is responsible for adapting the game demand, sets the lower limit too high and adapts too quickly, so that the cognitive overload becomes visible very quickly, especially in MCI-patients.* [E-08: project manager therapy]
>
> *One problem with the "Senso," in general, is that the physical intensity might well be higher.* [E-05: neuropsychologist]

Overwhelming task demands may cause frustration or refusal of games (f=6), although the feedback mechanisms to indicate errors work subtle (f=4). In contrast, games that are perceived as being too easy lead to boredom (f=2):

> *For example, the games "Targets," "Ski" or "Hexagon" are very confronting, and patients recognized quite quick: "Okay, I can't do it," and that frustrates patients. [...] Usually, these patients stop in the middle and say something like: "Ah, I don't need that kind of shit." Most of the time, they stop the training session immediately and don't want to continue anymore.* [E-08: project manager therapy]
>
> *My observation was that the negative feedback currently used does not demotivate the patients at all. It is also clear to the patients that they need to know when they are making mistakes and whether they are completing the tasks correctly.* [E-04: exergaming researcher]
>
> *Some of the negative feedback is so subtle that it is not even noticed.* [E-05: neuropsychologist]

T3: Motivators for Training

The experts described numerous motivators for training older adults with mNCD. The most frequently described motivators can be classified as intrinsically regulated motivators (f=44), which are directly related to exergames. Excitement, enjoyment, or fun is perceived as a central motivator for performing exergames (f=4). This was reported to be maintained by the captivating character of exergames (f=1) and multimodal animation (f=1), which is supported by specific game components (eg, game tasks or designs close to everyday life [f=6] or with personal relations or memories [f=1] including music or sound effects [f=8], animals or plants [f=4], landscapes [n=1], or colors [f=1]). In addition, patients were described as intrinsically motivated by gamification (f=6), the feeling of being optimally challenged (n=3), or simply by the variation of training (f=6):

> *For patients, the focus is primarily on having fun with the games. For example, they [...]liked watching birds and listening to birdsong and felt very motivated by the personal connection. Through these personal memories [...] a whole other level of motivation emerged.* [E-08: project manager therapy]

> *I think that those people who enjoy playing games are generally captured by the playful and competitive nature of the games. Furthermore, training with exergames is something completely different compared to classical therapy. Patients appreciate this change from the "dry" standard therapy.* [E-06: physical and occupational therapist]

However, when task demands become too high (f=6) or too low (f=2), patients have been observed to promptly lose their willingness to perform the exergames, as already reported. External motivators such as social support (eg, by therapists or caregivers) or group dynamics have also been reported to improve motivation to train (f=12). Feeling concerned about cognitive deterioration or being confronted by performance classifications can either motivate or induce negative feelings (f=7). Finally, some patients were also reported to be motivated by the effectiveness of exergames (f=2) or performance improvements (f=2):

> *I consider this social support to be very central. [...] If a relative joins in for motivation or support it can be very valuable.* [E-04: exergaming researcher]

> *I think there are always patients who don't want to know how well they are performing. Forcing performance feedback on such people can of course be motivating, but it could also be negative and confirm their limitations.* [E-07: physical and occupational therapist]

From the patients' viewpoint, all patients reported that they could primarily be motivated to train regularly by the effectiveness of the training, helping them achieve their individual success (f=13, n=8, 100%). Alternately, patients reported being motivated by their relatives or partners (f=2, n=1, 13%) and enjoyment of exercising (f=1, n=1, 13%). Having to travel to a training facility was reported to have a negative effect on training motivation and adherence (f=4, n=1, 13%):

> *It would be nice if I could go for a walk in the forest again without falling down. I used to do this four times a week for 75 minutes. It motivates me to train so that I can do this again in the future.* [P-02]

> *It would motivate me if I could improve my abilities (balance) again. [...] I would like to stay independent and modern, not to be called an old lady.* [P-03]

> *The success. I no longer need to be motivated. If I set my mind to it, I do it!* [P-08]

T4: Training Goals and Outcomes

Regarding the training goals, cognitive functioning (f=19) should be targeted in the training intervention in the experts' viewpoint while also addressing ADLs and mobility (f=3), addressing physical capabilities (f=3), and accounting for psychosocial factors (f=2), such as feelings of insecurity. However, the weighting of the training focus differs significantly between experts in different fields:

> *[...] higher order processes (i.e. divided attention or the ability to plan) are affected in most patients. Therefore, it is important to focus on these higher order cognitive functions.* [E-05: neuropsychologist]

> *I think that the coupling of brain functions with physical functions is central. At the same time [...]it is important to focus on what is impaired. If the frontal lobe is impaired, it is certainly important to train executive functions, attention and inhibition.* [E-10: founder of an exergaming company]

> *Primarily physical activation, especially that people get moving and walk. But also, to train the intuitive way of taking steps. [...] The cognitive aspects of the training have always played a subordinate role for me, but they were usually not decisive for the success of the therapy, as this was often trained differently, and I am not an expert in this.* [E-06: physical and occupational therapist]

When asking experts about the training goals of patients, ADLs and mobility (f=5) were the most frequently stated in addition to cognition (f=3) and physical functioning (f=2). In addition, psychosocial factors (f=2) have been reported to include socializing or having fun:

> *I had patients who wanted to continue training because the training made them more confident in their gait. They felt better balance after the training.* [E-06: physical and occupational therapist]

> *The patients also see the cognitive aspects of the training, of course. [...] We often explain to the patients that falls prevention has a cognitive and physical aspect and that these aspects interact. Therefore, the patients mainly go to the training with the aim of improving their gait.* [E-07: physical and occupational therapist]

> *Some people really know what's going on and they know that they have a disease and that they can prevent or slow down the progression by doing physical activity and exergames. But then others don't really know that they have cognitive deterioration and they're just playing a game and having fun without specific training goals.* [E-09: exergaming researcher]
