Abstract

Background: Patients with breast cancer endure high levels of psychological and physical pain. Virtual reality (VR) may be an acceptable, safe intervention to alleviate the negative emotions and pain of patients with cancer.

Objective: We aimed to test the long-term effects of VR on psychological distress and quality of life (QOL) with traditional care in Chinese patients with breast cancer. We also explored the intervention mechanism and the acceptability of VR.

Methods: A total of 327 eligible participants were randomly assigned to a VR intervention group or a control group. The Distress Thermometer, QLQ-C30 (Quality of Life Questionnaire version 3.0), and Virtual Reality Symptom Questionnaire were assessed at baseline, postintervention (3 mo), and follow-up (6 mo). Analysis followed the intention-to-treat (ITT) principle. The generalized estimating equations model was used to analyze the longitudinal data, and the PROCESS macro was used to analyze the mediating effect.

Results: Compared with the control group, patients with breast cancer in the VR group had lower distress scores (*P*=.007), and higher health-related QOL scores (physical, role, emotional, cognitive, and social functioning) after 6 months (*P*<.05). Psychological distress had mediating effects on the longitudinal association between VR and the health-related QOL (indirect effect=4.572 - 6.672, all *P*<.05).

Conclusions: VR intervention technology may help reduce distress and improve QOL for patients with breast cancer over time. By incorporating a mediating analysis, we showed that the QOL benefits of VR intervention was manifested through positive effects on psychological distress risk factors.

KEYWORDS
virtual reality; breast neoplasms; quality of life; psychological distress; longitudinal studies

Introduction

Breast cancer is a common malignant tumor throughout the world [1]. With the progress of detection and treatment technology, the survival rate of patients with breast cancer has been greatly improved. However, increasing numbers of studies have also paid attention to the adverse psychological and physiological sequelae caused by breast cancer surgery or chemotherapy [2,3]. Patients with cancer are at several times the risk of psychological disorders due to lack of normal life, communication, and interaction [4-6]. Other symptoms related to chemotherapy such as nausea, vomiting, and anorexia are frequently reported [7]. These may affect treatment compliance and quality of life (QOL). From 2020, COVID-19 has been spreading around the world. In the process of fighting the pandemic, the normal operations of the hospitals were affected [8]. The postponement of re-examinations for some patients with cancer, interregional hospitalization, and self-isolation have all increased patients' emotional distress [9]. In addition, patients have less access to the outside world and have lost normal social interactions. Psychological needs are even less satisfied, with considerably increased loneliness [10]. Without timely intervention and treatment, a poor mental state might cause tumor progression and deterioration [11].

Virtual reality (VR) is a 3D virtual scene that simulates reality, generated by a computer. It immerses the user in a virtual environment by using specific human-machine interfaces, such as a head-mounted display, a set of wired gloves, a position tracker or other controllers to experience a sense of presence or immersion [12]. Specifically, it is an artificial environment that is experienced through sensory stimuli such as images and sounds provided by a computer. In this environment, our behavior can partially determine our feelings [13]. In recent years, especially in the health system, the emergence of this technology provided patients with a safe environment for intervention and treatment [14-17]. Its effectiveness stemmed from the fact that patients could focus on pleasant or interesting stimuli rather than unpleasant symptoms [18]. These techniques were generally categorized as distraction interventions. By using head-mounted devices, VR immersed patients in computer-generated views while engaging various senses, providing a comprehensive stimulus that helped isolate patients from the hospital environment [19].

Previous studies have confirmed that the VR interventions could alleviate chemotherapy pain and enhance the QOL for patients with cancer [20]. However, research on the mediating mechanisms between VR and QOL remains limited. Among the potential mediating mechanisms, the most widely accepted hypothesis was that VR improves emotional states. Patients who experienced less anxiety, more fun, and more positive emotional valence during VR distraction were more likely to report subjective pain reduction [21]. Specifically, when patients experienced more enjoyment, painful treatments became more tolerable [22], potentially enhancing their self-efficacy and, consequently, improving their QOL [22,23]. These studies suggested that the relationship between VR and the QOL in patients with cancer might have been mediated by emotional regulation. Therefore, it is necessary to verify the effectiveness and obtain the best clinical practice evidence.

Some studies on VR had some limitations, for example, most of the trials lacked a control group [23,24], and the sample size was small (n<50) [25-27]. Owing to the lack of repeated exposure and long-term follow-up results [28-30], it has not been adequately established whether the effects of VR could endure for longer timespans beyond the usage of the device. Our main objective was to explore the long-term effects of VR in reducing distress and some chemotherapy symptoms, as well as improving the QOL for patients with breast cancer in China. Moreover, we further explored whether or not psychological distress mediated the effect of VR interventions on the health-related QOL.

Methods

Study Design and Setting

This study was a single-blinded randomized controlled trial, and was registered in the Chinese Clinical Trial Registry (registration ChiCTR2000035049). Patients were randomly assigned (1:1) to the VR group and control group by block randomization with varying block sizes of 4. The random sequence was generated using the Random Allocation Software (version 23; IBM Corp) by a graduate student who was not involved in the intervention or data collection. Sequentially numbered, opaque, sealed envelopes were prepared by the student. Before the first chemotherapy (baseline, T0), all the participants completed the informed consent form and a baseline questionnaire. Afterward, the second and third questionnaires were completed in the third month (post intervention, T1) and the sixth month (follow-up, T2), respectively. The content of the measurement includes both physical symptoms and psychological and emotional aspects.

Participants

This study was conducted in the Cancer Hospital of China Medical University, which is a public cancer treatment center in northeastern China, from April 2020 to March 2021. The selection criteria were as follows: (1) a confirmed diagnosis and treatment of breast cancer for the first time, and a plan to undergo chemotherapy; (2) aged 18 to 79 years; and (3) complete cognition, normal reading ability, and barrier-free communication. The exclusion criteria were as follows: (1) doctors assessed life expectancy to be less than 6 months, (2) patients with emotional illness, and (3) patients who were receiving other forms of psychotherapy. All participants provided informed consent.

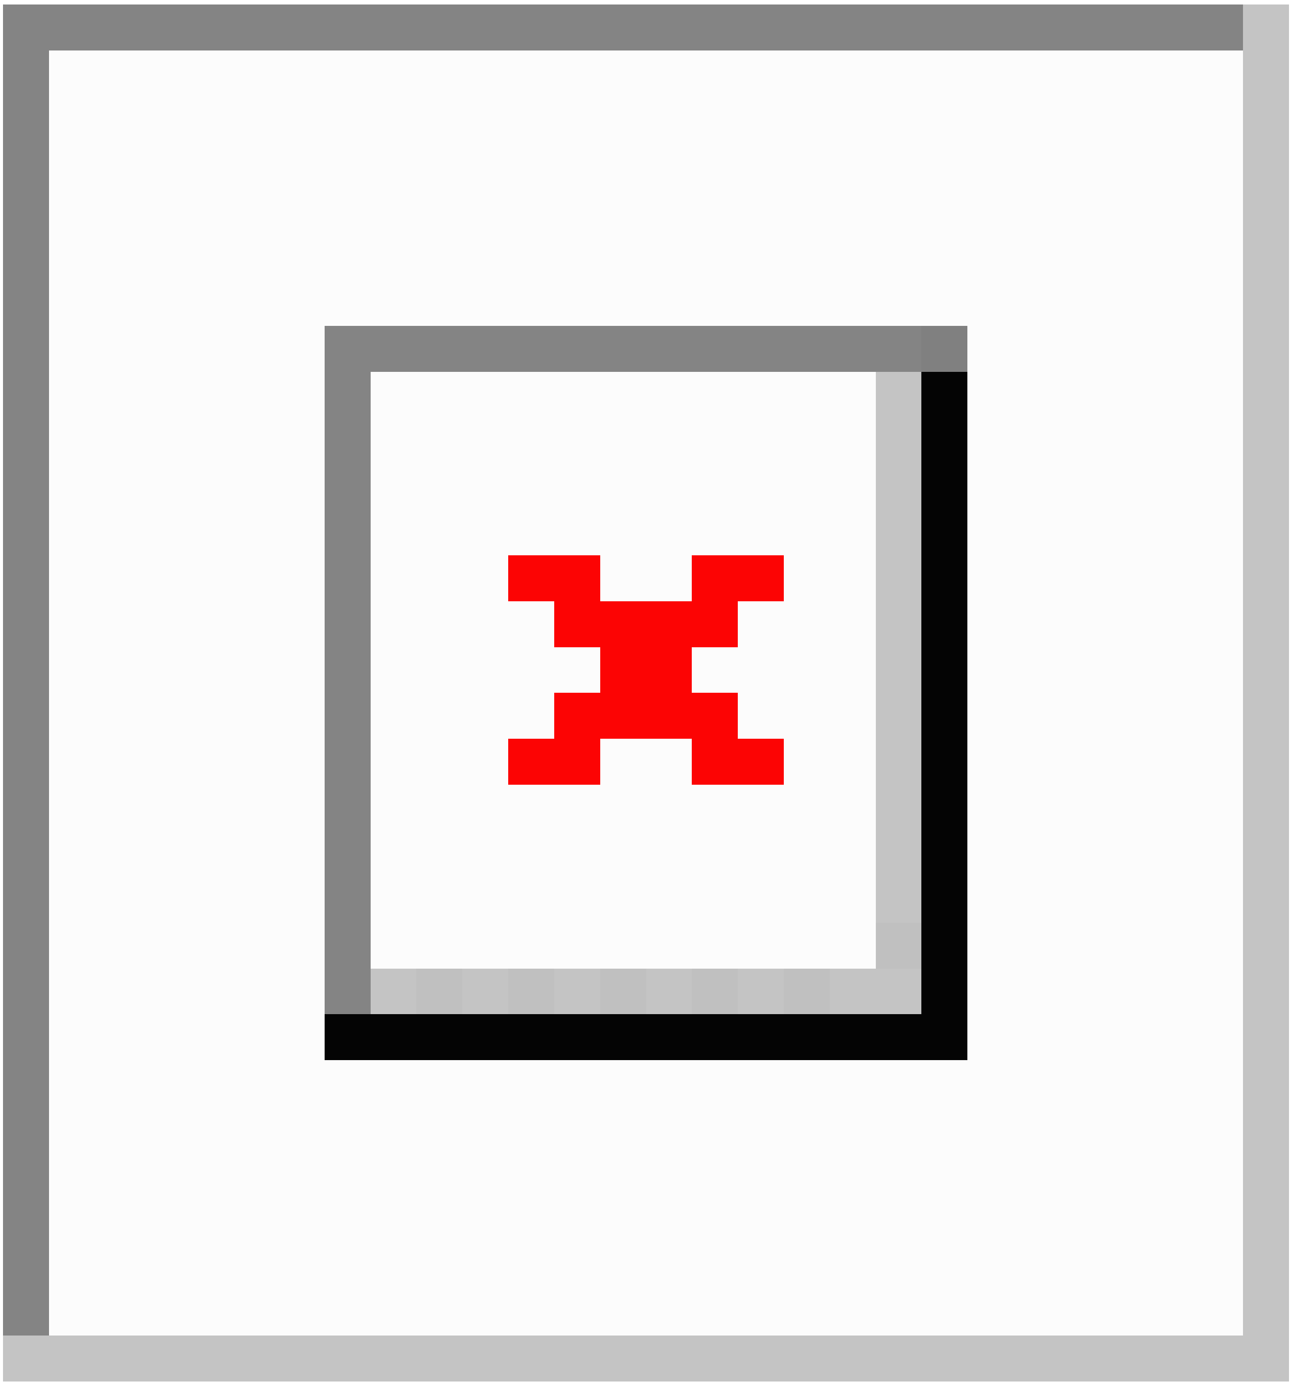
Sample Size

The sample size was calculated using the G*Power (version 3.1; Heinrich-Heine-Universität Düsseldorf) program. Based on a 2-sided significance level of .05, an effect size of 0.6 for distress outcome [31], the 2-arm parallel trial power of 0.80, and a 35% attrition rate, a minimum of 130 participants per group was needed.

Intervention Content and Frequency

The VR device consists of 2 parts: a headset (VIVES110) and a hand controller. Our team developed 3 virtual environments in total for participants to choose freely, and embedded a voice guidance system in the device to help participants relax. Patients could complete explorations such as walking through the forest, walking on the beach, and sightseeing at sea, or relaxation training according to the voice guidance (Figure 1). The intervention trial was a 12-week VR training. The nurses guided participants to wear the device during chemotherapy intervals or during breaks, and to participate for 15 - 20 minutes 1 to 2 times a week in the hospital. All participants had to have at least 12 interventions before T1. After each VR intervention, participants reported whether they had possible adverse symptoms. The participants in the control group only underwent chemotherapy as per the treatment plan in the hospital, and refrained from beginning any VR treatment.

Figure 1. (**A**) shows how a virtual reality (VR) device was used during the intervention; (**B**) shows one of the screen captures from the VR experiences.



Measurements

Demographic and Clinical Information

Participants completed a standardized self-report in the first round of questionnaires, including age, residence, marital status, education level, employment status, and disease stage.

Distress

The Distress Thermometer (DT) [32] is a single-item, self-report measure of psychological distress. The DT has an 11-point range from 0 (no distress) to 10 (extreme distress). Patients were asked to choose the number that best describes how distressed they have been in the past week.

Health-Related QOL

The QOL of the patients with cancer was measured using the Chinese-language translation of the validated European Organization for the Research and Treatment of Cancer QLQ-C30 (Quality of Life Questionnaire version 3.0) [33]. The QLQ-C30 includes a global health status or QOL scale [QL], 5 functional scales (physical [PF], role [RF], emotional [EF], cognitive [CF], and social [SF]), 3 symptom scales (fatigue, pain, and nausea and vomiting), and 6 single-item symptom scores. All scale scores range from 0 to 100, with a high score on the functional scales indicating a high level of functioning and a high score on the symptom scales indicating greater severity of individual symptoms.

Motion Sickness

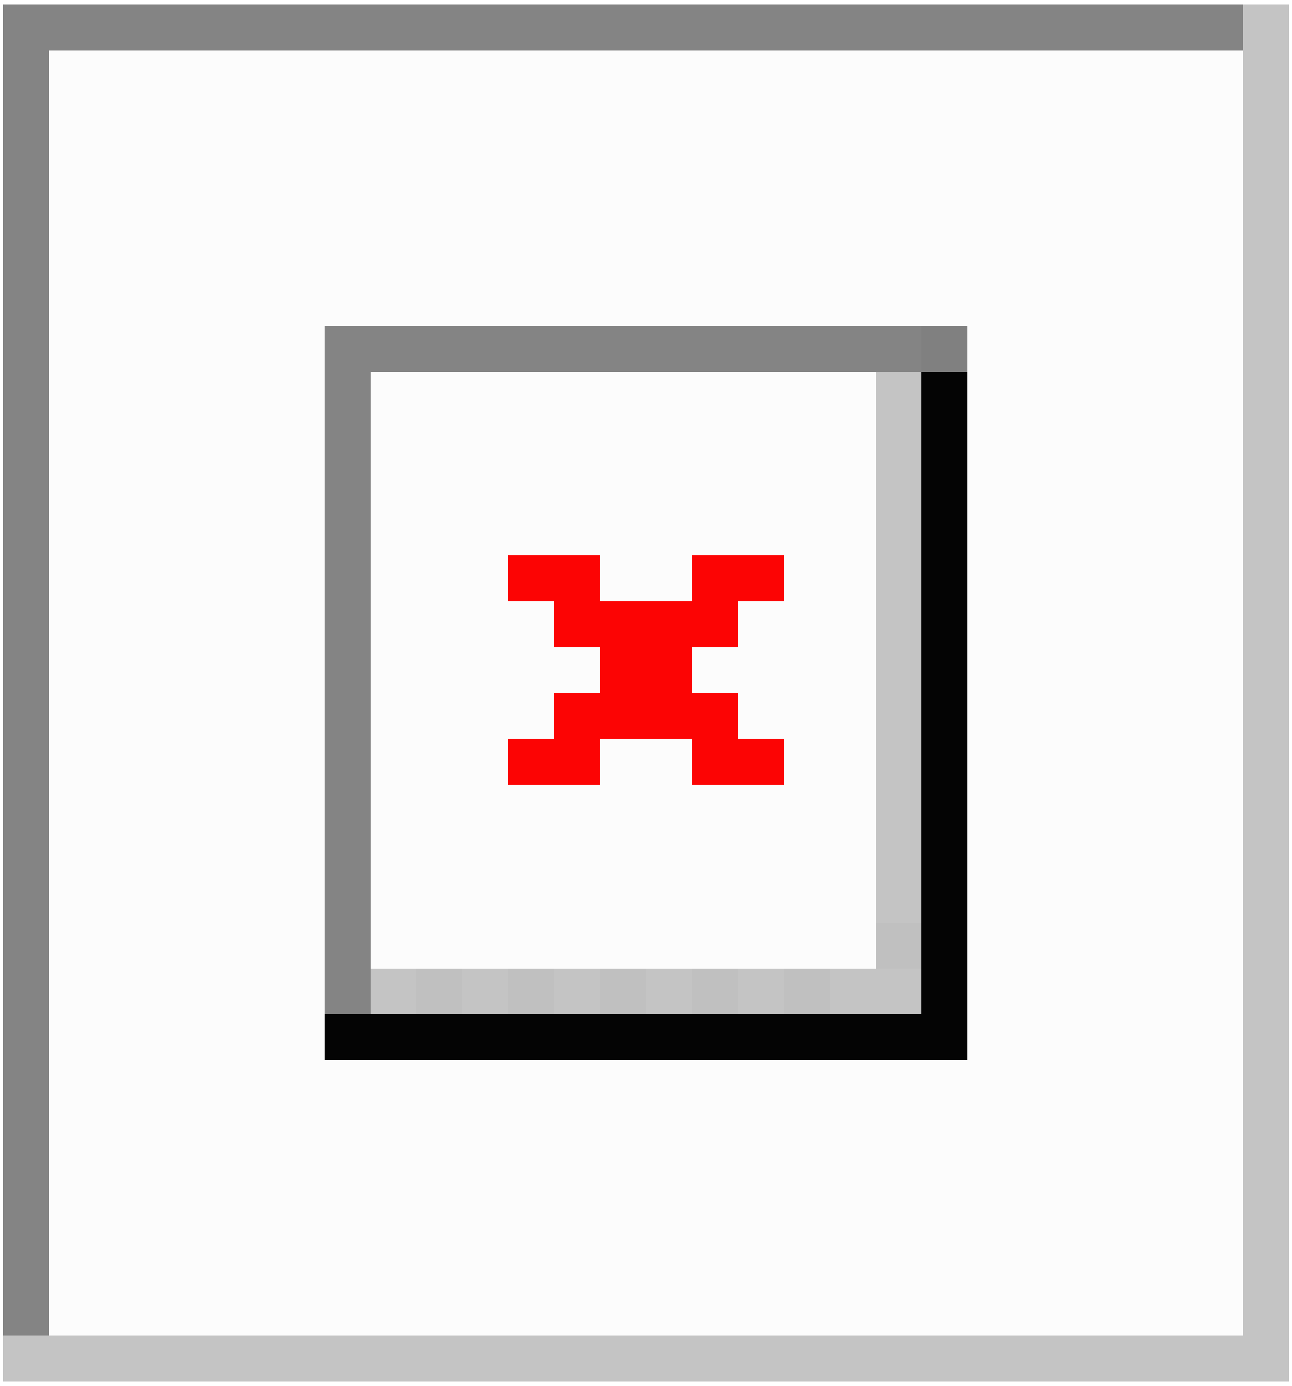
The Virtual Reality Symptom Questionnaire (VRSQ), which was developed by Ames et al [34] in 2005, was used. After the VR intervention, the VRSQ was completed to evaluate the possible symptoms of motion sickness that may occur in a VR environment. The questionnaire assessed 8 general physical side effects (general discomfort, fatigue, boredom, drowsiness, headache, dizziness, concentration difficulties, and nausea) and 5 visual effects (eye fatigue, eye pain, blurred vision, and difficulty focusing). The score ranges from 0 to 6, indicating a degree of symptoms from none to very severe.

Data Analysis

The analysis for this study was performed using IBM SPSS Statistics software (version 23). Appropriate descriptive statistics were used to summarize the characteristics and outcome variables of the participants. The *t* test, chi-square test, and the Wilcoxon signed-rank test were used to evaluate between-group differences. The intention-to-treat (ITT) principle was adopted for outcome analysis [35]. A generalized estimating equations (GEE) model is an extension of the quasi-likelihood method and is often used to analyze longitudinal data [36]. The characteristic of this data is the correlation between the multiple observation points for the same individual, which cannot be processed by the general linear model. The GEE model can solve the correlations between longitudinal data, as well as missing data. In this study, the GEE model was used to evaluate the effects of VR intervention on the changes of QOL and distress scores of patients with breast cancer at various time points (T0, T1, and T2). All statistical tests involved were 2-sided with the level of significance set at 0.05.

We used mediation analysis to investigate the relationship between the VR intervention at T0 and the health-related QOL at T2, with the psychological distress at T2 as a mediator (Figure 2). A mediator variable was defined as a third variable that changed the association between an independent and dependent variable [37]. It provided additional insight into information about the causal links between 2 strongly associated variables. The PROCESS macro with model 4 was used and, to ensure the stability of the path coefficient estimates, the analysis for the mediation model was supplemented with 5000 bootstrap replications. The significance of the indirect effect was examined by the bias-corrected 95% CI after bootstrapping. An indirect effect was considered statistically significant if the 95% CI did not include 0.

Figure 2. Hypothesized mediation model (a, b, and c′=unstandardized regression coefficients): indirect effect=a×b; direct effect=c′, total effect c=sum of indirect and direct effects=a×b+c′.



Ethical Considerations

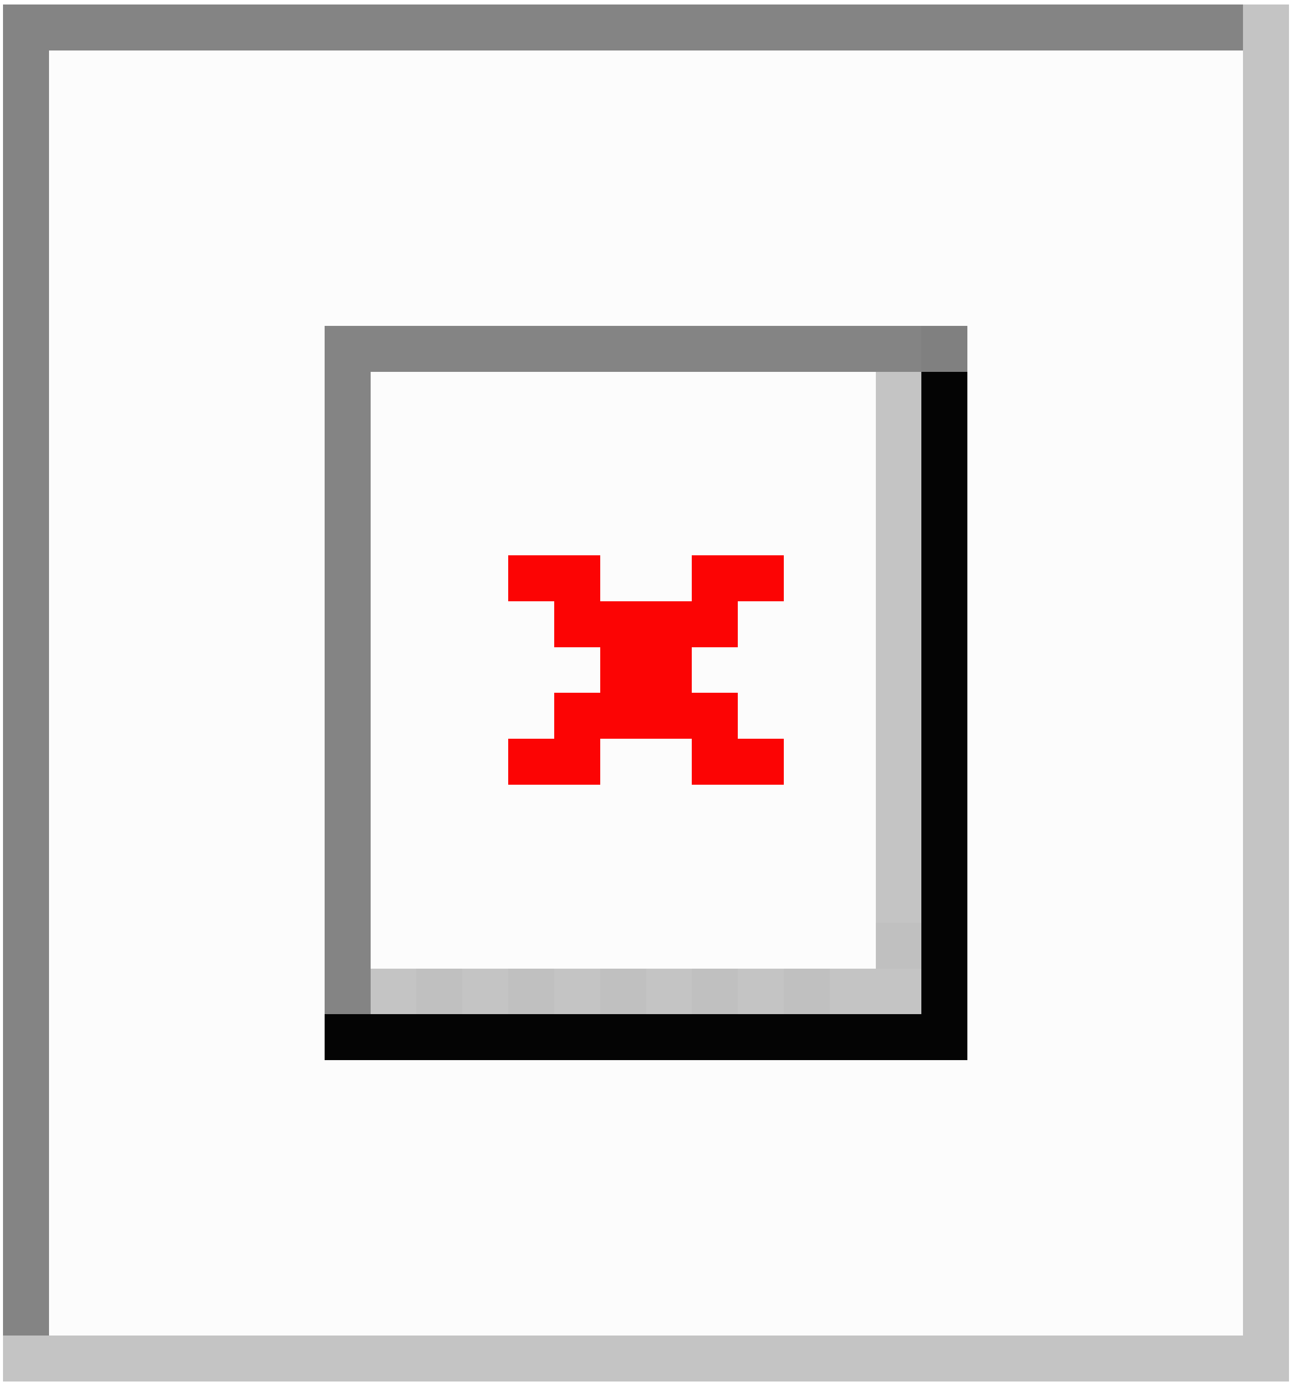
This study was performed in line with the principles of the Declaration of Helsinki. Approval was granted by the Ethics Committee of the Liaoning Cancer Hospital & Institute (reference 20200301-2). Each participant provided written informed consent to take part in the study. For the images with a participant' face and body (Figure 1), the author had obtained permission to publish in the study.

Results

Recruitment

As shown in the CONSORT (Consolidated Standards of Reporting Trials) flow diagram (Figure 3; see checklist in Multimedia Appendix 1), 500 participants were screened for eligibility. Among these patients, 120 were excluded because they did not meet the criteria, and 53 declined to participate because of lack of time or interest, or for no specific reasons. Ultimately, 327 participants were recruited, although 97 participants failed to complete the reassessment at T1 or T2, and 18 participants did not have enough interventions. The T1 and T2 attrition rates were 25% and 14%, respectively, and the overall attrition rate was within our acceptable range. We compared the baseline characteristics between those who completed the study and those who dropped out from the study, and there were no significant differences (Multimedia Appendix 2).

Figure 3. CONSORT diagram. CONSORT: Consolidated Standards of Reporting Trials; VR: virtual reality.



Demographics and Clinical Characteristics

The participants' average age at diagnosis was 54.3 (SD 9.58) years, and of whom 216 (66.1%) were residents of a city, 198 (60.6%) had below middle school–level education, 267 (81.7%) were married, and 294 (89.9%) had no family history of cancer. More than half of the participants had an annual personal income of less than CN ¥20,000 (US $2838.61). In total, 263 (80.4%) participants had cancer at stage I or II. At the baseline, there were no differences between the 2 groups in either sociodemographic or clinical variables (Table 1).

Outcome Variables at Baseline

Overall, there was no significant difference between the 2 groups in each scale score at baseline (*P*<.05). In total, 245 (74.9%) patients scored ≥4 on the DT and had psychological distress. At the same time, participants in both groups reported low QOL at T0. Detailed scores are shown in Table 2.

Table . Mean scores of the outcome variables for intervention and control groups across study time points and the baseline comparisons.

Effects of VR Interventions

Effects on Distress

As shown in Figure 4 and Table 3, compared with T0, DT scores in the VR group gradually decreased at T1 and T2 (T1: mean 3.27, SD 1.81; T2: mean 3.01, SD 1.96), and this change was significantly different from that in the control group, as indicated by the interaction term of group×T1 (β: −1.049, 95% CI −1.635 to −0.445; *P*=.001) and group×T2 (β: −.947, 95% CI −1.635 to −0.258; *P*=.007).

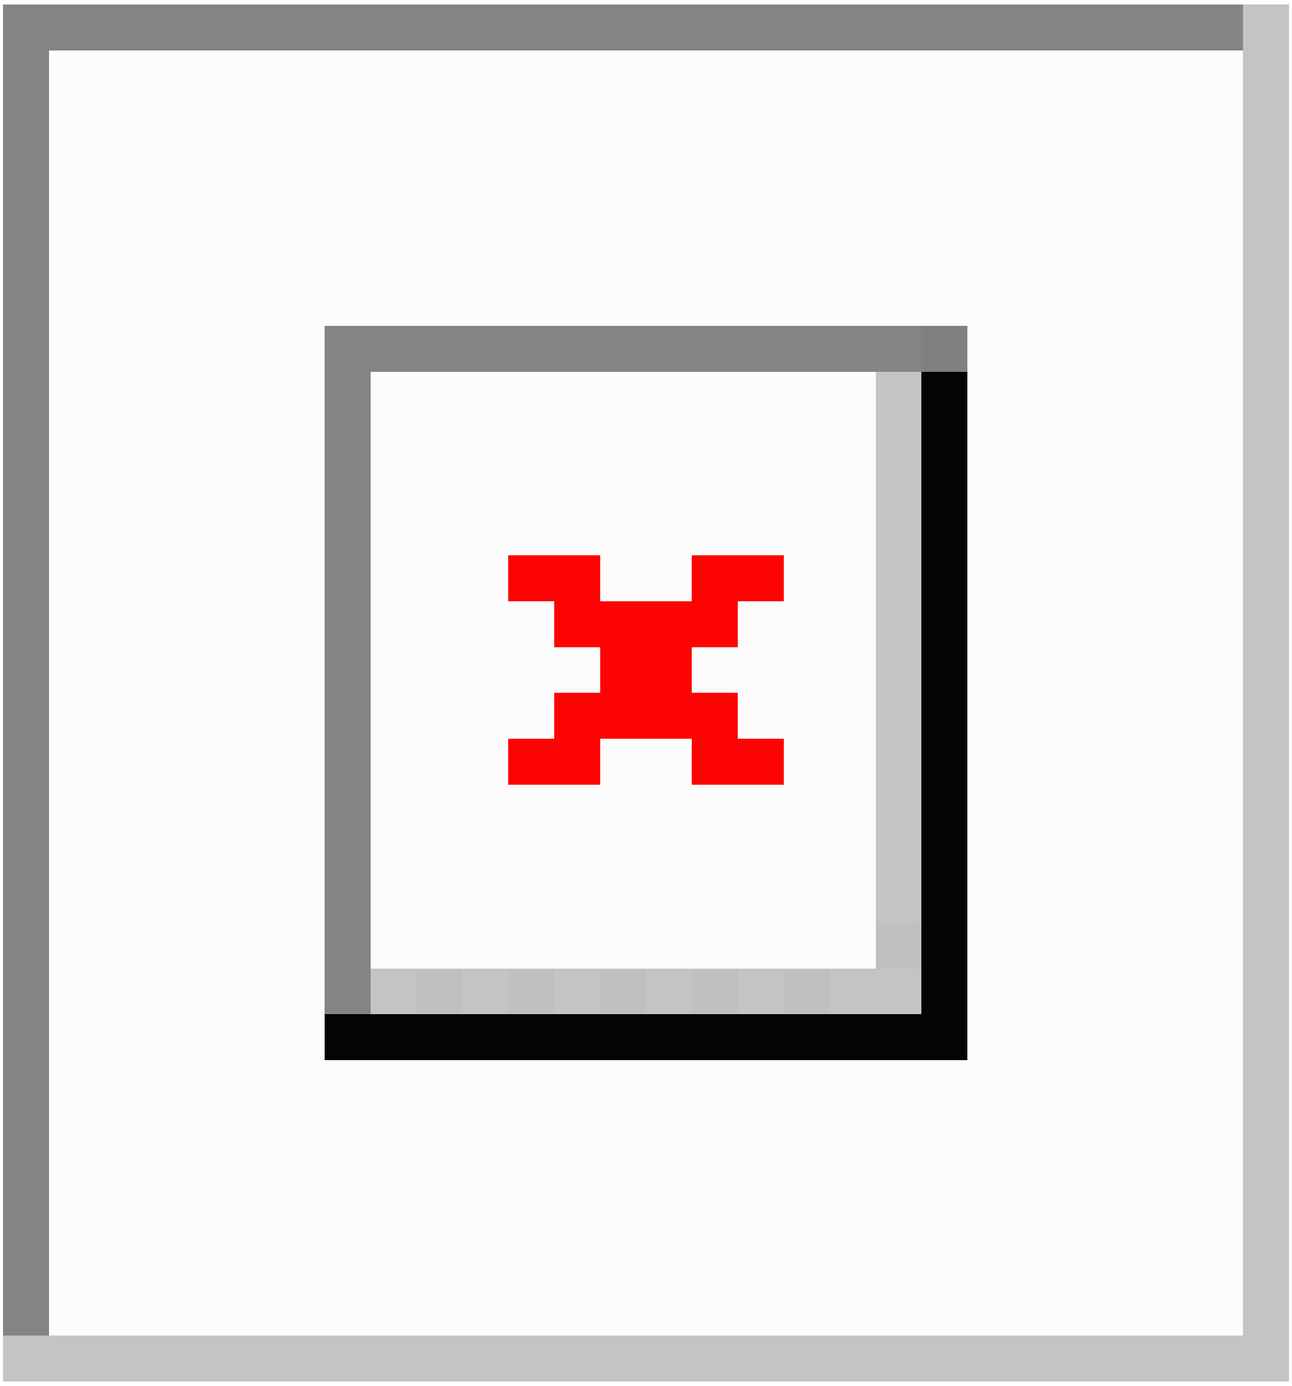
Effects on Health-Related QOL

As shown in Figure 5, the VR group showed a great improvement in the global health status scale at T1 and T2 but, when compared with the control group, statistical significance was not reached (group×T1: *P*=.30 and group×T2: *P*=.06). In terms of functional subscales, significant differences between the changes in the 2 groups were observed in the PF and RF scales at T2 (*P*=.001 and .02), and in the EF, CF, and SF scales at both T1 and T2 (*P*<.05; Table 3). At the same time, we also analyzed the other symptom subscales. Nausea and vomiting, appetite loss, dyspnea, and other symptoms of participants in the VR group were also significantly improved at different time points with respect to T0 (*P*<.05), as shown in Multimedia Appendices 3 and 4.

Figure 5. Mean scores on each dimension of quality of life in the virtual reality and control groups between the 3 time points of data collection. VR: virtual reality.



Results of the Mediating Analysis

According to the GEE model, the VR group had significantly greater improvement in distress compared with the control group across the preintervention and postintervention time points. The differential changes between the 2 groups supported the further exploration of the mediating roles. Table 4 shows that psychological distress had a significant indirect effect on the global health status in the participants of the VR group (indirect effect=6.245; 95% CI 2.965, 10.282). Similarly, the effects of VR on 5 health-related functional subscales were also mediated by improving psychological distress (indirect effect=4.572 - 6.672, *P*<.05).

Table . Mediation analysis results for the virtual reality effects on health-related quality of life via distress. The virtual reality intervention group at T0 was set as the independent variable (X), the global health status and 5 functioning subscales at follow-up T2 were set as dependent variables (Y), and the distress at T2 as a mediator (M). * *P*<.05.

Cybersickness Symptoms

Some cybersickness symptoms related to VR were analyzed through VRSQ. Data showed that in the first month of intervention, the frequency of patients with each symptom was less than 20% (32/163; Multimedia Appendix 5).

Discussion

Principal Findings

This study demonstrated that VR technology may help reduce distress and improve the health-related QOL of patients with breast cancer over time. By incorporating a mediation analysis, we showed that the QOL benefits of VR are manifested through its positive effects on psychological distress risk factors.

Psychological distress is a common side effect of cancer treatment. In 2018, a cross-sectional study completed by our team showed that 56.5% of cancer survivors had psychological distress and scored ≥4 on the DT [38]. However, the outbreak of COVID-19 aggravated the emotional distress of patients with cancer. In this study, the proportion rose to 74.9% (245/327) and it was necessary to take appropriate intervention measures to reduce the psychological pressure. VR allows patients to be completely engaged in an immersive environment, which may help distract them from noxious stimuli, thereby relieving psychological stress [19,28]. In our study, the distress level was significantly reduced in the VR group compared with the control group (undergoing usual care). This longitudinal effect did not disappear over time, suggesting that the effect of VR was not simply due to the novelty of the experience [22]. Yang et al [39] proposed a 4-layer theoretical framework of a potential VR intervention for mental health. Based on the hypothesis, VR delivers predictability in an unpredictable environment, and helps patients cope with their stress, evokes emotion, and diverts attention [40].

VR has shown promise in improving health status among patients with breast cancer [41]. Reynolds et al [30] reported that participants with metastatic breast cancer who were subjected to VR experiences showed clinically significant decreases in fatigue, stress, and pain during the trial and at follow-up. However, many studies focus on the efficacy of in-the-moment distraction from treatment, and the long-term effects of VR are still missing. Some of our preliminary findings are encouraging. The longitudinal effects of VR could be sustained at least for 6 months. At the same time, these positive effects were not only shown in the dimensions of PF and EF of QOL, but also in the dimensions of RF, CF, and SF, and even some chemotherapy side effects such as vomiting and insomnia were improved and relieved to varying degrees. This was also a comprehensive assessment of the effects of VR on QOL. In addition to the clear effect on pain management [42,43], this study also provided more possibilities for VR in improving patients' QOL and chemotherapy tolerance. In the future, VR may be considered for incorporation into the clinical setting to provide a convenient, attractive, and easily applied intervention.

The psychological and physiological fields are the most commonly studied areas for VR [26,44]. In our study, we focused on relatively stable hospitalized patients undergoing chemotherapy rather than surgical patients. We agree with Espinoza et al [45] that VR technology shifted patients' attention to the selected scene track, and reduced their attention to pain or anxiety. However, presumably this distraction effect did not occur in the days after the removal of the device, and so could not fully explain the maintenance of VR. Our other important finding was that psychological distress could play a mediating role in the VR-QOL interaction, which provides an explanation for the persistence of VR. Psychological factors play an important role in the development and regression of tumors [46]. Generally speaking, a good state of psychological health can stimulate a number of body functions and significantly boost the effectiveness of the chemotherapy [47]. Our results confirmed once again that improved mood can promote positive health outcomes and QOL. Several design characteristics of our VR system, such as guided relaxation and soothing music, support the mediation theory of positive mood. These observations further suggest that the intervention mechanism of VR is multifactorial, being mediated by attentional, cognitive, and emotional effects [48].

Owing to the specificity of the disease, the impact of the COVID-19, and the long study period, some participants dropped out of the study, and the overall attrition rate reached 35%, which was similar to previous studies [31] and within our estimated range. However, among the lost participants, only 18 patients were lost due to the substandard intervention frequency, accounting for less than 16%. At the same time, the VR equipment we used was comfortable to wear, and the designed scenes were natural. We also assessed the possible side effects of VR devices through the VRSQ scale, but all symptoms occurred at a frequency of less than 20%, which was considered negligible [49]. These findings are important and demonstrate that VR intervention can be a viable and acceptable treatment for patients with breast cancer [30].

Limitations

Although this study had several strengths and extended the literature on the use of VR, it was not without limitations. First, loss of muscle strength leading to a decrease in limb functionality is also a common complication seen in breast cancer survivors. This VR system did not incorporate exercise rehabilitation training such as improving patients' upper limb mobility, so the research on the effects of VR was incomplete. Second, although we designed 3 intervention scenarios, and required each patient to achieve multiple VR interventions, we did not further analyze the impact of the duration and frequency of interventions, and did not verify the effect of repeated VR exposure. Third, this study assessed the effects of VR through self-reported measures, but because the participants, investigators, and nurses were unlikely to be blind, this could have introduced bias into some of the results. In future, physiological indicators (such as stress-related molecules or brain waves) can be used to monitor changes and evaluate the effects of VR.

Conclusions

This study found that VR has the potential to sustainably relieve the level of distress and improve the QOL in women with breast cancer. Importantly, the positive results were sustained for at least 6 months. Furthermore, reducing emotional distress was identified as one of the possible mechanisms by which VR affects QOL. As physicians, it is our duty to participate in the development of these innovations to meet the clinical need for effective nonpharmacologic adjuncts, especially for patients with cancer or during special times such as the pandemic. We suggest that future research should be carried out in multiple centers and medical institutions to verify the effectiveness with other cancer treatments and to explore more possibilities for VR interventions.

Abstract

Background: Public health education plays a crucial role in effectively addressing infectious diseases such as COVID-19. However, existing educational materials often provide only foundational information, and traditional group education faces challenges due to social distancing policies.

Objective: Addressing these gaps, our study introduces a serious game called "Flattening the Curve." This interactive experience immerses learners in the role of quarantine policy managers, offering unique insights into the effects and challenges of social distancing policies.

Methods: The development of the game adhered to the SERES framework, ensuring a scientifically designed foundation. To achieve its learning objectives, the game incorporated learning and game mechanics including an agent-based infection model, a social distancing policy model, and an economic model, which were developed based on previous literature. After defining a broad concept of scientific and design foundations, we used a participatory design process. This study included 16 undergraduates and took place over one semester. Participants played the game, gave feedback, and answered surveys. The game was improved based on participants' feedback throughout the process. Participants' feedback was analyzed based on the Design, Play, and Experience framework. Surveys were conducted before and after the activity and analyzed to assess participants' evaluation of and satisfaction with the game.

Results: The game successfully achieved its learning objectives, encompassing a comprehensive understanding of infectious disease characteristics; the disease transmission process; the necessity and efficacy of quarantine policies and their delicate balance with economic factors; and the concept of flattening the curve. To achieve this, the game includes the following: (1) an agent-based infection model based on the modified Susceptible-Exposed-Infectious-Hospitalized-Recovered (SEIHR) model with five infectious disease scenarios; (2) a quarantine policy model with social distancing, travel control, and intensive care unit management; and (3) an economic model that allows users to consider the impact of quarantine policies on a community's economy. In response to participatory design feedback, the game underwent meticulous modifications, including refining game systems, parameters, design elements, the user interface, and interactions. Key feedback included requests for more scenarios and engaging yet simple game elements, as well as suggestions for improving the scoring system and design features. Notably, concerns about the fairness of the outcome evaluation system (star rating system), which could incentivize prioritizing economic activity over minimizing casualties, were raised and addressed by replacing the star rating system with a progress-based vaccine development system. Quantitative evaluation results reflect participants' positive assessments of the game through the learner-centric approach.

Conclusions: The serious game "Flattening the Curve," developed through a participatory design approach, emerges as a valuable tool for public health education, particularly concerning social distancing policies. The game and its source code are openly accessible online, enabling widespread use for research and educational purposes.

Introduction

Background

Since December 2019, the COVID-19 pandemic has profoundly impacted global society, affecting numerous domains such as daily life, health care, and education, among others. In an effort to mitigate the impacts of COVID-19, governments worldwide have implemented a range of social distancing measures, including compulsory mask wearing, curfews, stay-at-home orders, and lockdowns. However, the implementation of these policies has led individuals to experience economic, social, and psychological loss, resulting in diminished trust in their respective governments [1,2]. This sense of loss and eroded trust are fueling public rejection of social distancing policies and even leading to active defiance of governments. Indeed, several countries experienced increased public protests due to the social distancing policies [3-5].

People's noncompliance with social distancing policies can be attributed to various reasons. Previous research suggests that these reasons include a lack of knowledge about infectious disease and health, misunderstanding, and misinformation about mitigation policies [6-9]. To effectively prevent and control the transmission of infectious diseases such as COVID-19, adherence to public health policies, including quarantine measures, is crucial. Additionally, fostering public comprehension of the necessity and rationale underpinning these policies is of paramount importance [3].

To achieve these objectives, effective communication with the public and the provision of education aimed at enhancing the general public's understanding of policy validity and scientific knowledge are necessary. Currently, educational resources pertaining to infectious diseases predominantly focus on health-related information and individual behaviors, while the development of materials designed to foster comprehension of national- or community-level social distancing policies remains insufficient. Moreover, the majority of training materials employ a unilateral instructional approach, relying on simplistic documents, images, and videos. These conventional methods generally prove inadequate in fostering public empathy toward the policy-related challenges confronted by quarantine officers. On the other hand, game-based learning using serious games is known to increase education effectiveness and learning motivation through the interactive and participatory nature of games [10-12].

Due to the COVID-19 pandemic, the demand for health and safety education has increased, and many researchers have developed and used serious games for COVID-19–related education. The primary education topics include COVID-19 knowledge [13-15] or infection prevention behaviors and perceptions [10,15-18]. Since serious games are suitable for distance education and e-learning (posing less of a concern in terms of infection), they are an educational method that has been in the spotlight for many researchers in the pandemic era, coinciding with an increase in online education [19-22].

Earlier studies found that game-based learning could result in higher knowledge acquisition [12,23] and, more importantly, that games could make their players motivated and satisfied [11,23]. Digital game–based learning enabled by serious games can make a learning environment more active, engaging, and immersive, which is important for effective learning [24]. However, most game-based health and safety education focused on teaching safe behavior, knowledge, and adequate use of personal protective equipment to prevent COVID-19 infection. The transfer of mere knowledge has limitations in imparting an understanding of why compliance with quarantine policies is necessary and how the policies work. Therefore, by using existing education, learners were not properly motivated to go beyond personal safety behaviors and comply with quarantine policies. A serious game for quarantine policy education will be a fundamental driving force for the public to learn why the social distancing policy must be followed rather than just how to comply with it.

Objective

The objective of this study was to address a critical gap in existing educational resources for quarantine policies by developing an engaging and interactive learning tool. To achieve this objective, the game incorporates scientifically designed game-based learning mechanics including an agent-based infection model, a social distancing policy model, and an economic model. Furthermore, a participatory design (PD) process was conducted, with this learner-centric approach enhancing the educational effectiveness of the game. This study endeavors to enhance public understanding of quarantine policies by disseminating the developed serious game through web platforms, thereby promoting informed decision-making and adherence to quarantine measures.

Methods

General Study Design

To effectively deliver quarantine policy education addressing infectious diseases to the public, we developed a serious game named "Flattening the Curve" (FTC). The serious game used in this study was designed in a form that could motivate learners' interest while conveying scientific facts. The game was developed using the SERES framework [25]. The SERES framework is a 5-step framework for developing health care serious games. It has been applied to the development of various health care serious games and gamified e-learning materials.

In addition to using the SERES framework, the game was developed through a PD process to enhance the engagement and motivation of the learners [26,27]. PD is a research method in which users directly or indirectly participate in the design process and compose and interpret the design together with designers, researchers, and developers [28,29]. From an educational point of view, PD promotes learners' active engagement through motivation and internalization of concepts [30,31].

The design process was conducted as part of the undergraduate disaster management course at the Ulsan National Institute of Science and Technology, which was taught by the corresponding author during the second semester of 2021. Participants participated from the 2nd to the 15th week of the semester. To recruit participants, the authors explained to the participants the study's purpose, overall process, and tasks to be performed. The authors offered them the opportunity to participate in this activity as part of their coursework. All students voluntarily agreed to participate in the study.

This PD process reflected the iterative game design process, including design, prototype, and playtest [32]. Participants' comments and suggestions were analyzed and applied to the game using the 4 layers of the Design, Play, and Experience (DPE) framework [33]. During the PD process, participants answered two surveys, in the 3rd week and 14th week, respectively. Participants' key feedback and related implementation are presented in the Results section, and the details of the survey instrument are also presented in Multimedia Appendix 1.

Ethical Considerations

This study was reviewed by the Institutional Review Board at the Ulsan National Institute of Science and Technology and was determined to be exempt (UNISTIRB-21 - 58C). Due to the COVID-19 pandemic and the shift to remote learning, obtaining written informed consent was difficult. Therefore, verbal consent was obtained from all participants prior to their involvement in the study. All collected data were deidentified. There was no penalty for students who did not participate in part or all of the activity. Participants did not receive monetary compensation. However, to encourage active participation, participants who performed well in the activity were awarded extra credit for the course. This compensation was announced after all students had agreed to participate in the study, to ensure that the incentive did not coerce participation.

Scientific Foundations

The game was developed for people of all ages to facilitate an understanding of quarantine (social distancing) policies. Emphasis was placed on ensuring that the in-game explanations are easily comprehensible for players of all ages.

Understanding how and why a policy is important can lead to behavior changes in learners [34,35]. According to theories of human behavior related to safety and health, such as the Health Belief Model, the perceived benefits expected from engaging in certain behaviors can impact an individual's behaviors [36]. In other words, a thorough understanding of how quarantine policy benefits individuals and our society can influence an individual's compliance with policies. Thus, the primary learning objective of the game was for users to develop an understanding of the core concept of quarantine policies—"flattening the curve"—and recognizing the need for a balanced adjustment between preventive measures and economic consequences. Figure 1 illustrates the concept of flattening the curve, demonstrating how implementing social distancing measures can flatten the curve and consequently reduce the fatality rate [37]. In the absence of proper protective measures, the number of patients could easily overwhelm the health care system's capacity, resulting in inadequate treatment for some. Therefore, the point of flattening the curve is to ensure that more patients receive proper treatment, ultimately reducing the fatality rate [38]. Within the simulation, changes in the transmission pattern of infectious diseases can be observed according to policy implementation.

The game mechanics should be designed based on proper scientific foundations. Several models were suggested to predict the spread of the epidemic and the effect of social distancing policy [39-41] (Figure 2). Kermack and McKendrick [42] first proposed the Susceptible-Infectious-Recovered (SIR) model to explain the spread of infections transmitted from person to person through mathematical approaches. SIR is the most fundamental infectious disease model, consisting of Susceptible, Infectious, and Recovered or Removed compartments. Anderson and May [43] introduced the SEIR model, which includes an additional Exposed condition (latent period or incubation period). SEIHR is a model that extends the SEIR model by incorporating an isolated (Hospitalized) condition [40]. Further, Yang et al [41] suggested another modified version of SEIR: SEMCR, which divided the infectious stage into mild (M) and critical (C) cases. Patients in the critical stage have a higher probability of death.

Figure 1. An illustration of the concept of “flattening the curve.” Slowing the spread of infection is essential to ensure that people have easier access to treatment, while also allowing time to gradually increase the capacity of the health system.

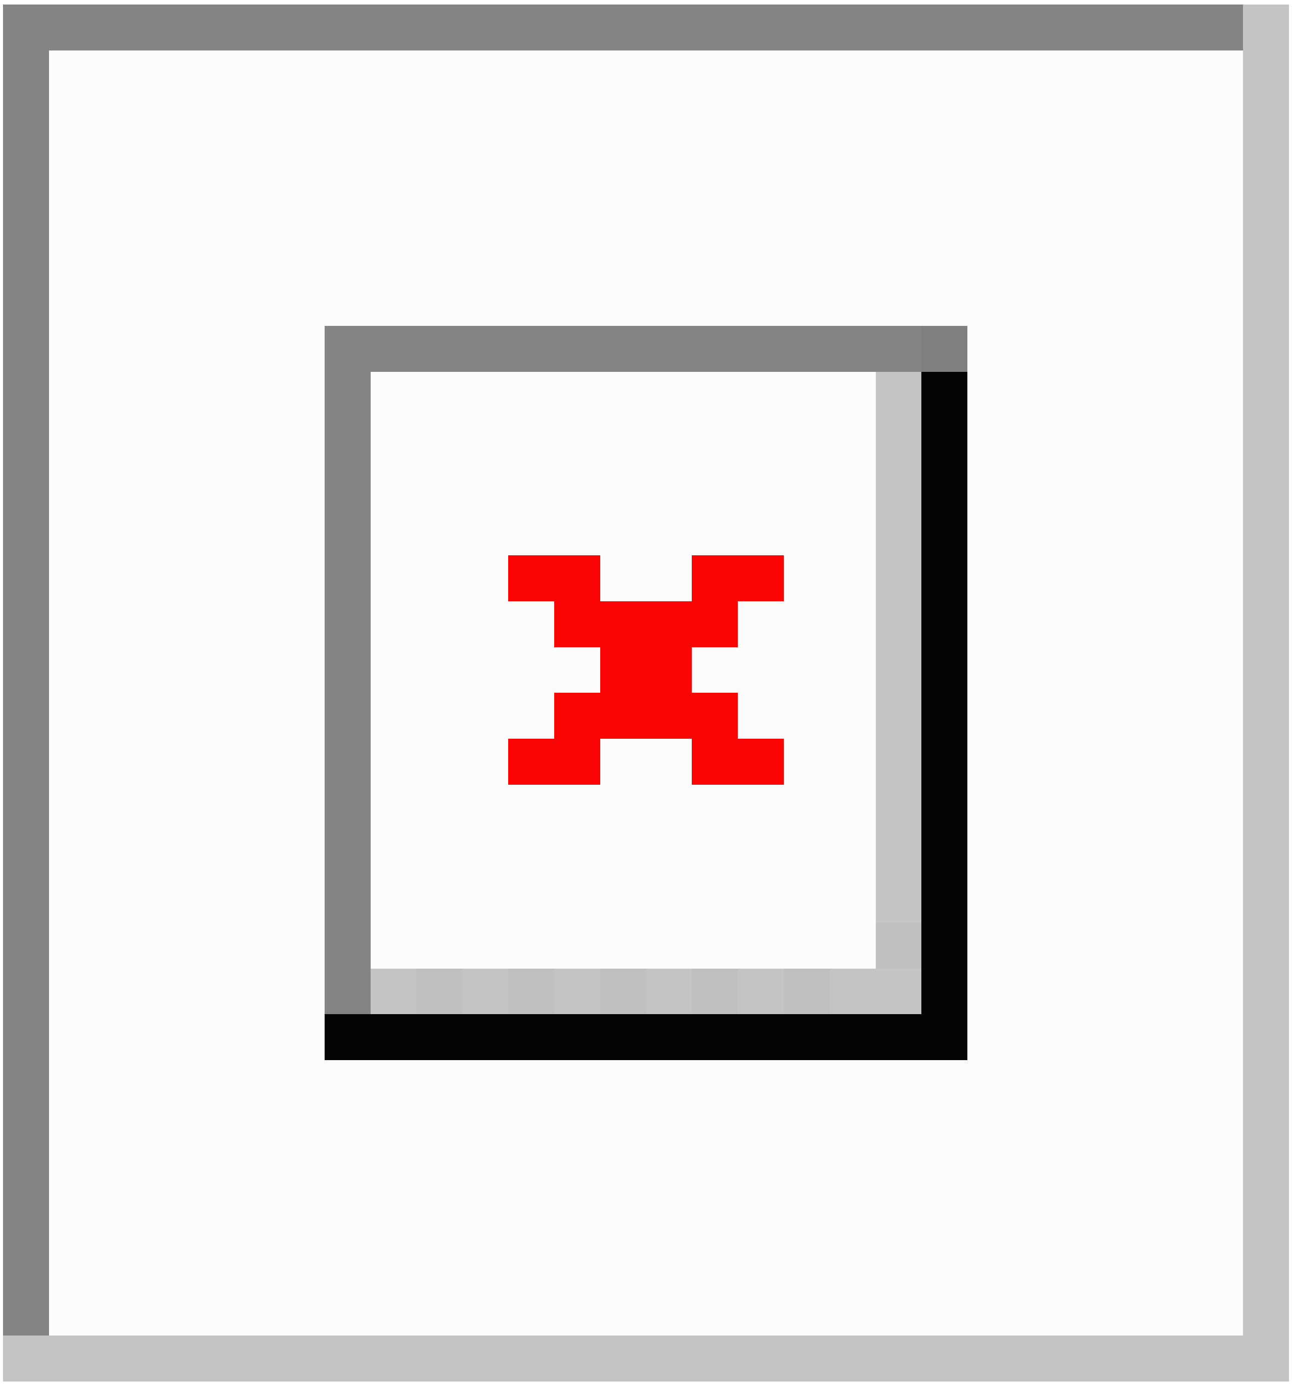

Figure 2. Flowcharts of epidemic models, edited from previous studies [39-41]. C: critical; D: dead; E: exposed or latent period; H: hospitalized; I: infectious; M: mild; R: recovered; S: susceptible.

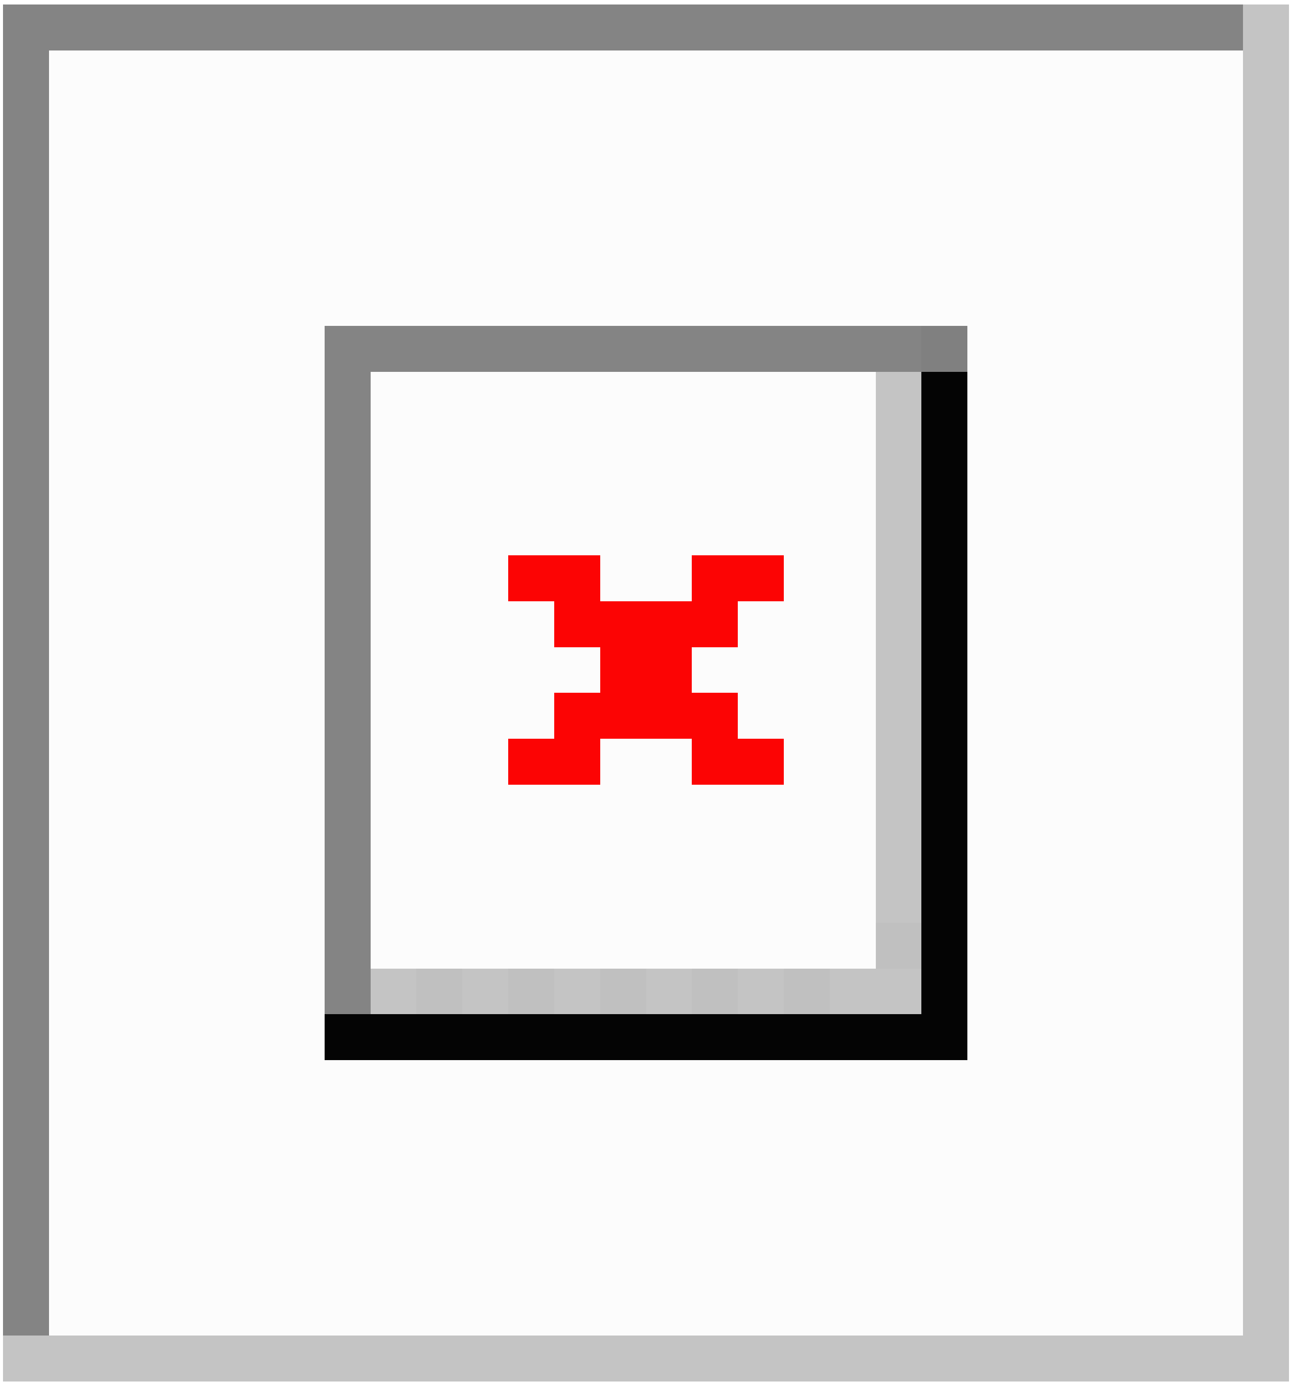


In the FTC game, we applied a modified epidemic model by integrating SEIHR [40] and SEMCR models [41] to distinguish between mild and critical cases and also include the hospitalized condition.

Based on the modified epidemic model, the game was designed to model various well-known infectious diseases, such as COVID-19 (Delta and Omicron variants), measles, and Ebola virus. Major characteristics of diseases, such as reproduction number and mortality rate, were adjusted based on statistical data [44-50]. Characteristics of COVID-19 variants were based on statistics provided by the Korea Disease Control and Prevention Agency [51]. The implemented infectious disease transmission model has been consulted and verified by a medical expert.

Social distancing is a public health strategy that aims to reduce the spread of infectious diseases [52]. It involves maintaining physical distance from others, avoiding large gatherings, and minimizing contact with individuals who are sick.

Researchers have employed various methods to implement social distancing in epidemic models. Social distancing is typically achieved by increasing the physical distance between people or reducing the number of physical contacts between individuals [41,53,54]. Agarwal et al [55] utilized daily movement rates to predict the number of deaths per day to evaluate the effectiveness of COVID-19 social distancing policies. Miksch et al [53] used location factors to make social distancing decrease the number of visitors to specific places such as schools and workplaces.

However, many educational materials related to infectious diseases have not adequately addressed the economic damage caused by the infectious diseases and the corresponding quarantine policies. Various social, health, and sanitary policies to prevent the spread of infectious diseases have been found to bring about negative economic impacts [56]. In the case of the United States, government measures such as business closures and restrictions on economic activities to slow the spread of diseases led to a record high in unemployment claims [57]. Therefore, we built economic elements into the game to help players learn about the economic impacts of quarantine policies.

Design Foundations

The general design of the serious game was established according to Winn's DPE framework [33]. At the initial stage of game development, we decided what types of learning and game mechanics should be included in the game based on the previous literature [58-60]. The game genre was decided to be a simulation, as its learning mechanism focuses on constructivist learning principles [60], which posit that learning draws upon prior knowledge to alter existing schema [61]. Using simulations, students have more opportunities to learn by doing, discover interesting infectious disease problems, and gain indirect experience in dealing with public health issues in the real world [62].

Design requirements considered the platform and accessibility to potential learners. The game was developed using JavaScript and published through a web page to be accessible to anyone. Following the players' feedback, visual enhancements were implemented to enhance the game's appeal to a younger audience.

Results

Design of the Serious Game

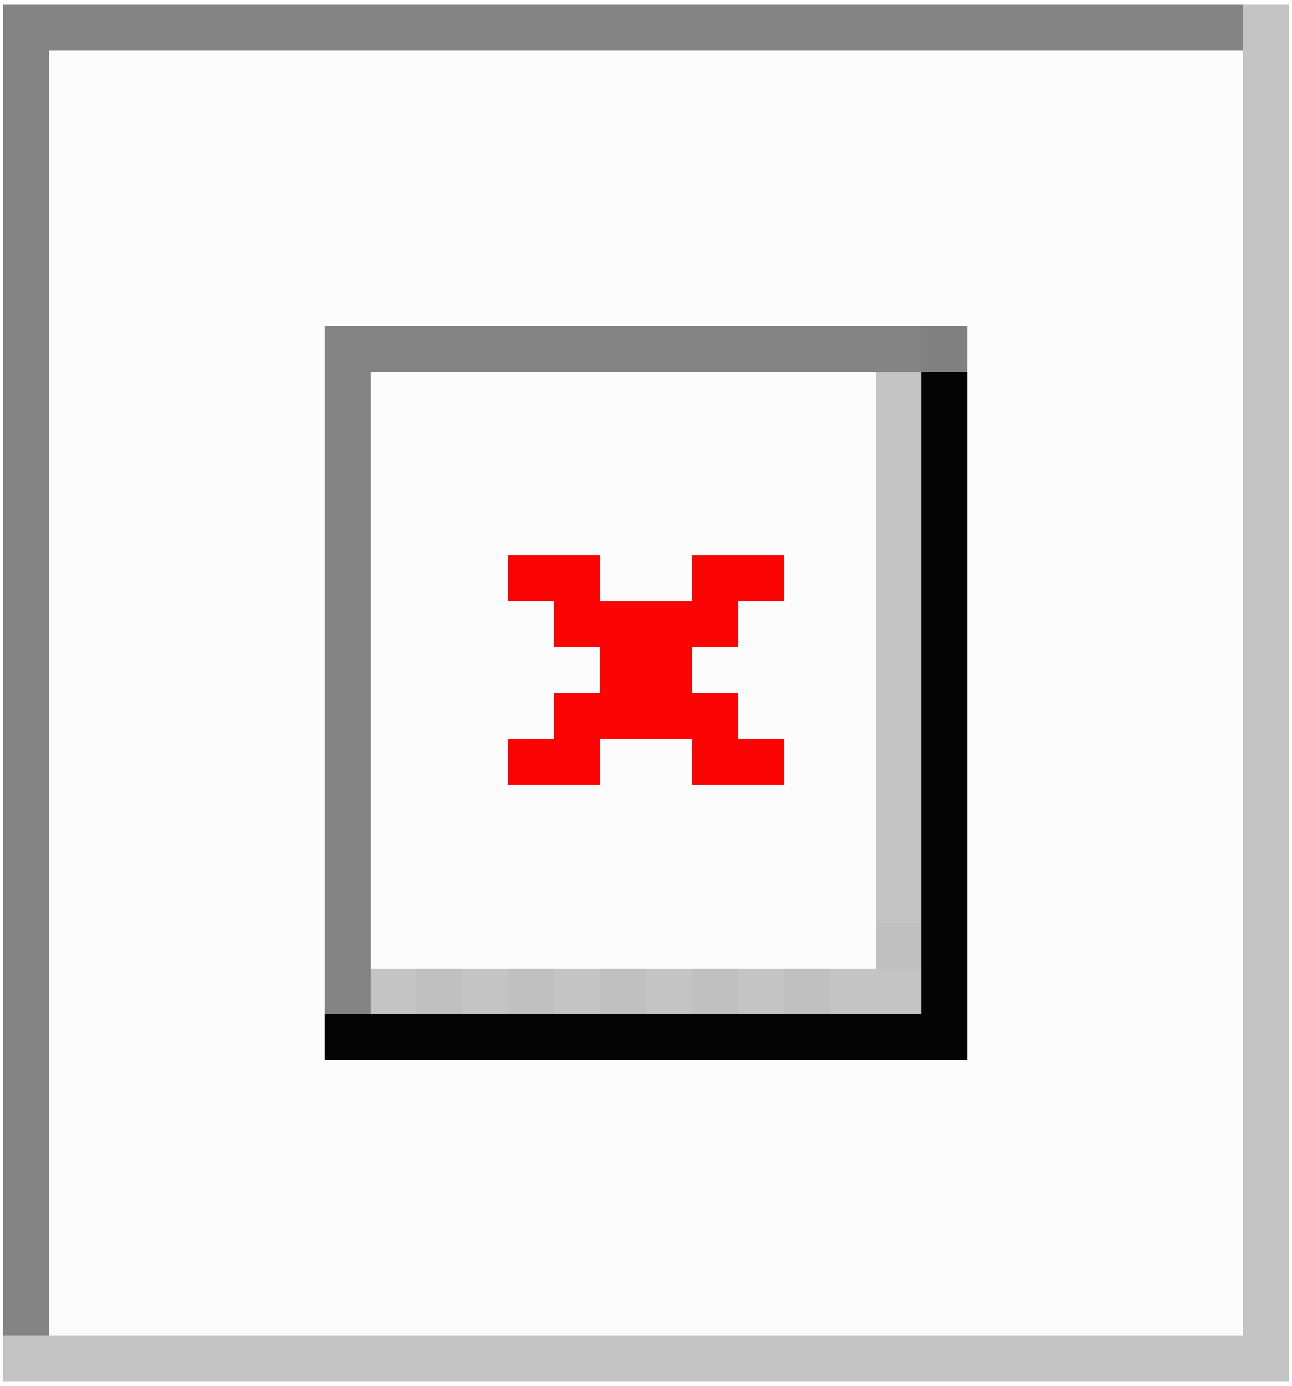
The game was developed as a turn-based strategic simulation game, with each turn corresponding to one week. In our interactive serious game, learners become a quarantine policy manager of a community. At the end of each week, users are allowed to choose appropriate quarantine measures. The spread of the epidemic is visualized on the game screen during the following week, and on weekends, users can check the status of the epidemic, apply quarantine measures, and continue on to the next turn. Players are provided with a budget necessary for implementing quarantine policies, which replenishes at the end of each month (every 4 weeks). The budget amount depends on the level of economic activity, as indicated by gross domestic product (GDP).

The objective of the gameplay is to minimize both casualties and economic damage until vaccine development is complete. Since the vaccine development speed depends on both the number of healthy people and GDP, faster vaccine development can be an indicator of a successful quarantine response.

To slow down the spread of disease, players should develop their own response strategies with various policies. These policies can be adjusted or changed on a weekly basis and each has its own advantages in reducing the spread of the disease. However, it is important for players to find a cost-effective combination of policies, as some have drawbacks (eg, social distancing policies may hinder economic activity, while policies such as travel control or increasing intensive care unit [ICU] capacity may require significant economic investments).

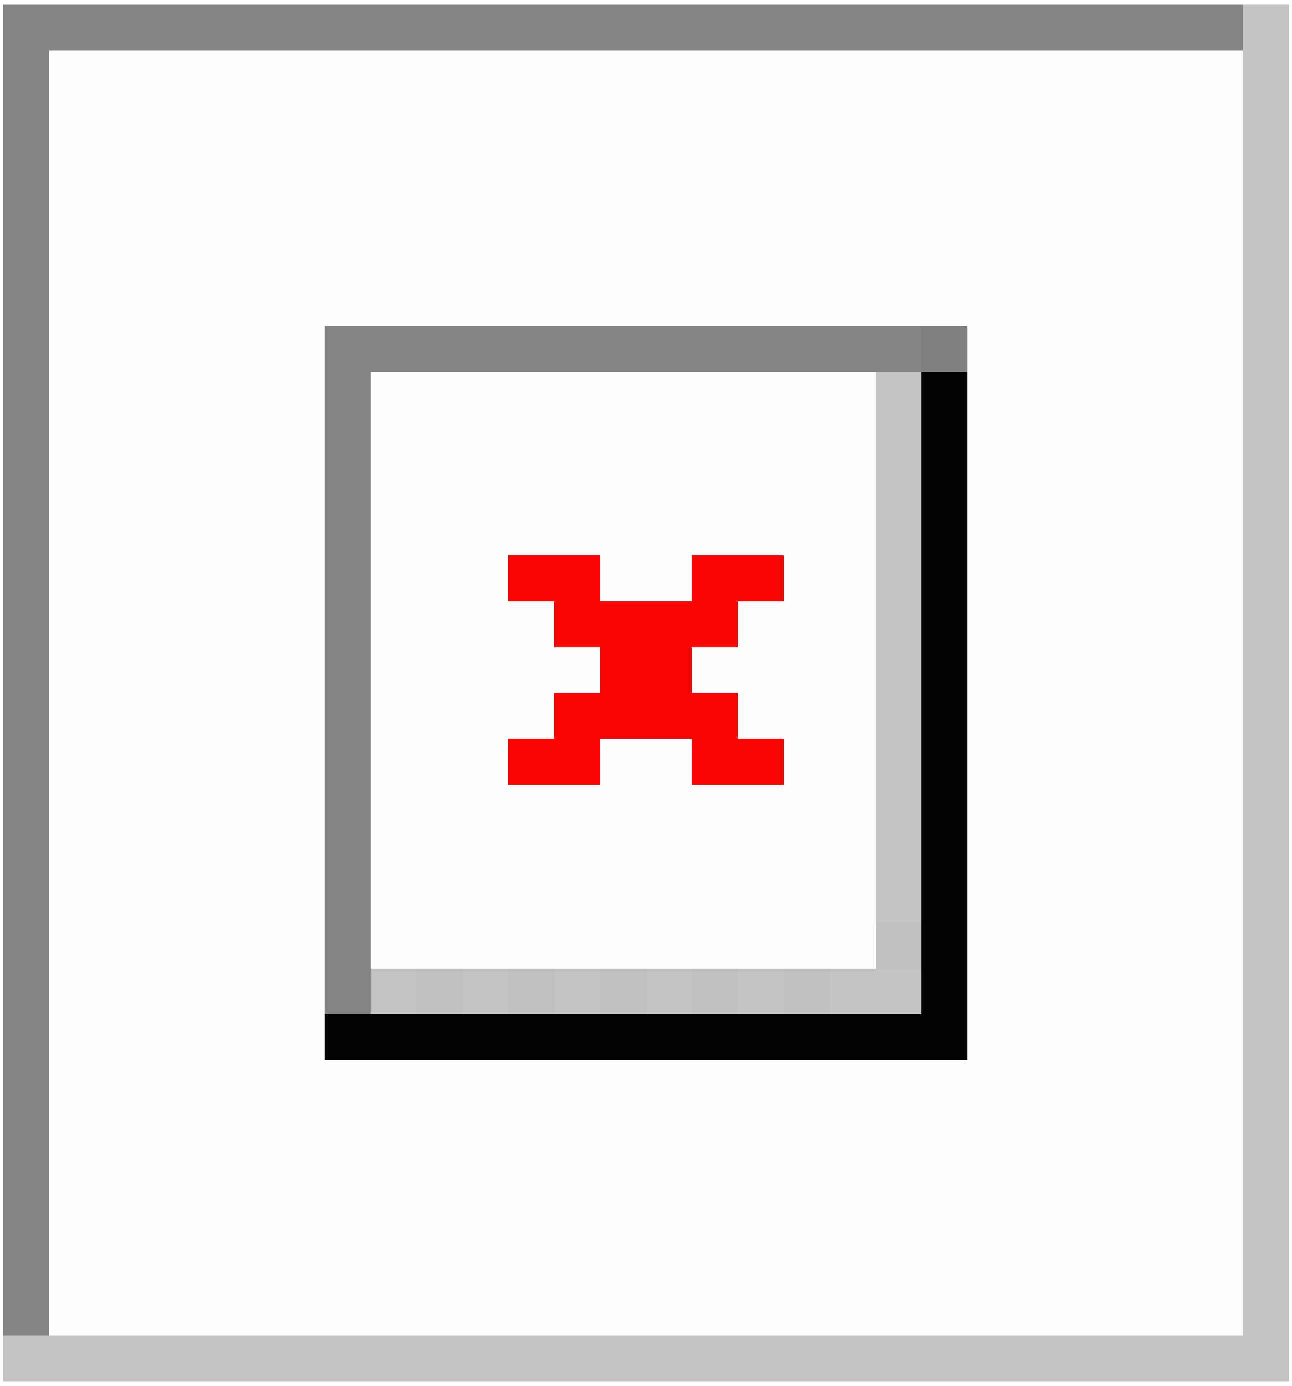
The game comprises 3 main panels: the simulation panel, information panel, and status panel (Figure 3). In the simulation panel, individuals are represented as round dots that move randomly. The color of each dot indicates its condition based on the modified SEIHR model. The information panel displays essential details about infectious diseases, such as the latent period, infectious period, infection rate, and severity. It also shows the number of people in each infectious stage, categorized according to the modified SEIHR model. The bottom of the panel features a graph illustrating overall disease trends.

Figure 3. Interface of the final version of the Flattening the Curve game. (A) Simulation panel: visualizes the agent's movements within the game environment. (B) Information panel: displays the current epidemic situation. At the end of each week, this panel also presents the weekly report. (C) Status panel: provides a summary of the key information. This panel also includes speed control and pause functions to allow players to adjust the pace of the game. GDP: gross domestic product; ICU: intensive care unit.



At the end of each week, the information panel transforms into the weekly report panel (Figure 4). Within the weekly report panel, there are two subtabs: Trends and Policy. The Trends tab includes tables and graphs that present the number of infections, critical cases, and deaths, as well as GDP, for the current week, providing a comparison with the previous week. This feature assists users in understanding more nuanced infection trends. In the Policy tab, players can implement age-based social distancing policies, implement travel control measures, and enhance ICU capacity.

Figure 4. Subtabs in the weekly report panel. (A) Trends tab. (B) Policy tab. GDP: gross domestic product; ICU: intensive care unit.



The status panel at the bottom consistently displays key information, including the current date, number of infections, ICU capacity, death toll, GDP, and budget status.

We made some important basic assumptions that make the game more explicit and learning oriented. These assumptions are carefully designed to ensure that the game retains its inherent learning capabilities and is sufficiently representative of the real world without becoming too complex. The assumptions are as follows.

1. Fixed population: there are 1000 people in the simulation at the start, with no population change due to death, birth, or migration outside of the epidemic.
2. Simplified interactions: a "contact" has occurred when dots overlap each other on the simulation panel.
3. Fixed border: the game world is assumed to have fixed rectangular boundaries and is divided into four in-game districts, whose geographic and social conditions are identical. This exists to determine the coverage of social distancing policies. There are no spatial features such as specific locations, workplaces, or homes.
4. Simplified economy: GDP is only influenced by how much people move around during the week. If social distancing policies are tightened or the number of deaths is high, people move around less, so the budget that the player receives decreases.

5. Simplified policy: quarantine policies, including the allocation of ICU beds, come into effect instantly, without any waiting or grace periods. In-game citizens do not raise objections to policies.

Application of the Scientific Foundation

Overview

The ultimate objective of the game is to comprehend the concept of flattening the curve, necessitating an understanding of infectious disease characteristics and control policies. There are 5 learning objectives in the game to achieve this. Figure 5 demonstrates a visualization of the learning objectives covered in the developed game.

The first learning objective focuses on understanding the characteristics of infectious diseases. The game incorporates characteristics of infectious diseases, such as the incubation period, transmission probability, and fatality rate. With the modified SEIHR model, the game simulates detailed infection and progression pathways. This interactive approach allows learners to gain insights into the distinct features and stages of various infectious diseases through gameplay of various scenarios.

The second learning objective involves understanding the process of disease transmission within society. The game takes the form of a city management simulation, effectively portraying the process of disease transmission as people move within the city.

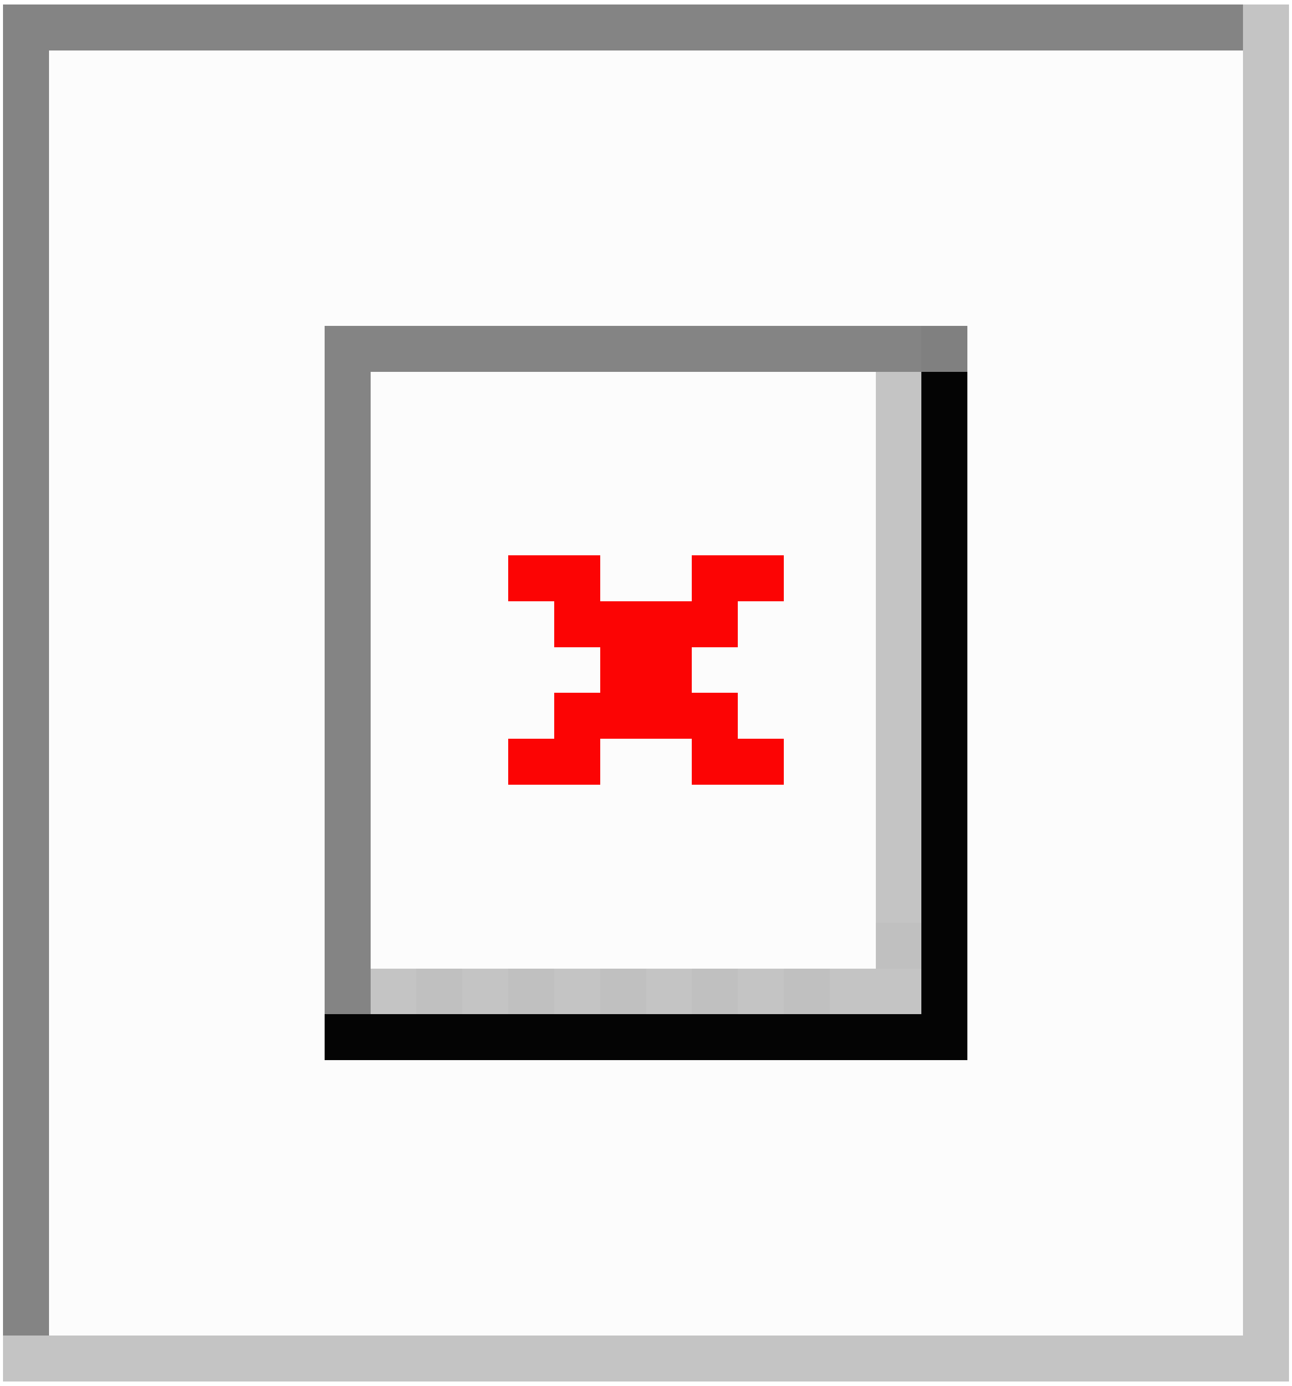
Building upon these objectives, the third learning objective emphasizes the necessity and efficacy of quarantine policies. During gameplay, learners are expected to actively participate in the implementation of quarantine policies in response to changing circumstances, thus developing a comprehensive understanding of the need for and effectiveness of policies.

The fourth learning objective addresses the balancing act between disease control policies and economic factors, illustrating the practical challenges of policy implementation. To convey the practical consequences of implementing quarantine policies, the game introduced economic concepts such as GDP and a budget, underscoring the imperative to strike a balance between epidemic control measures and economic considerations.

By building upon these 4 learning objectives, learners will eventually understand the concept of “flattening the curve” and gain the knowledge and skills to effectively manage infectious diseases.

All these learning objectives were delivered by scientifically designed game modules. The following sections describe how the modules were implemented in the game.

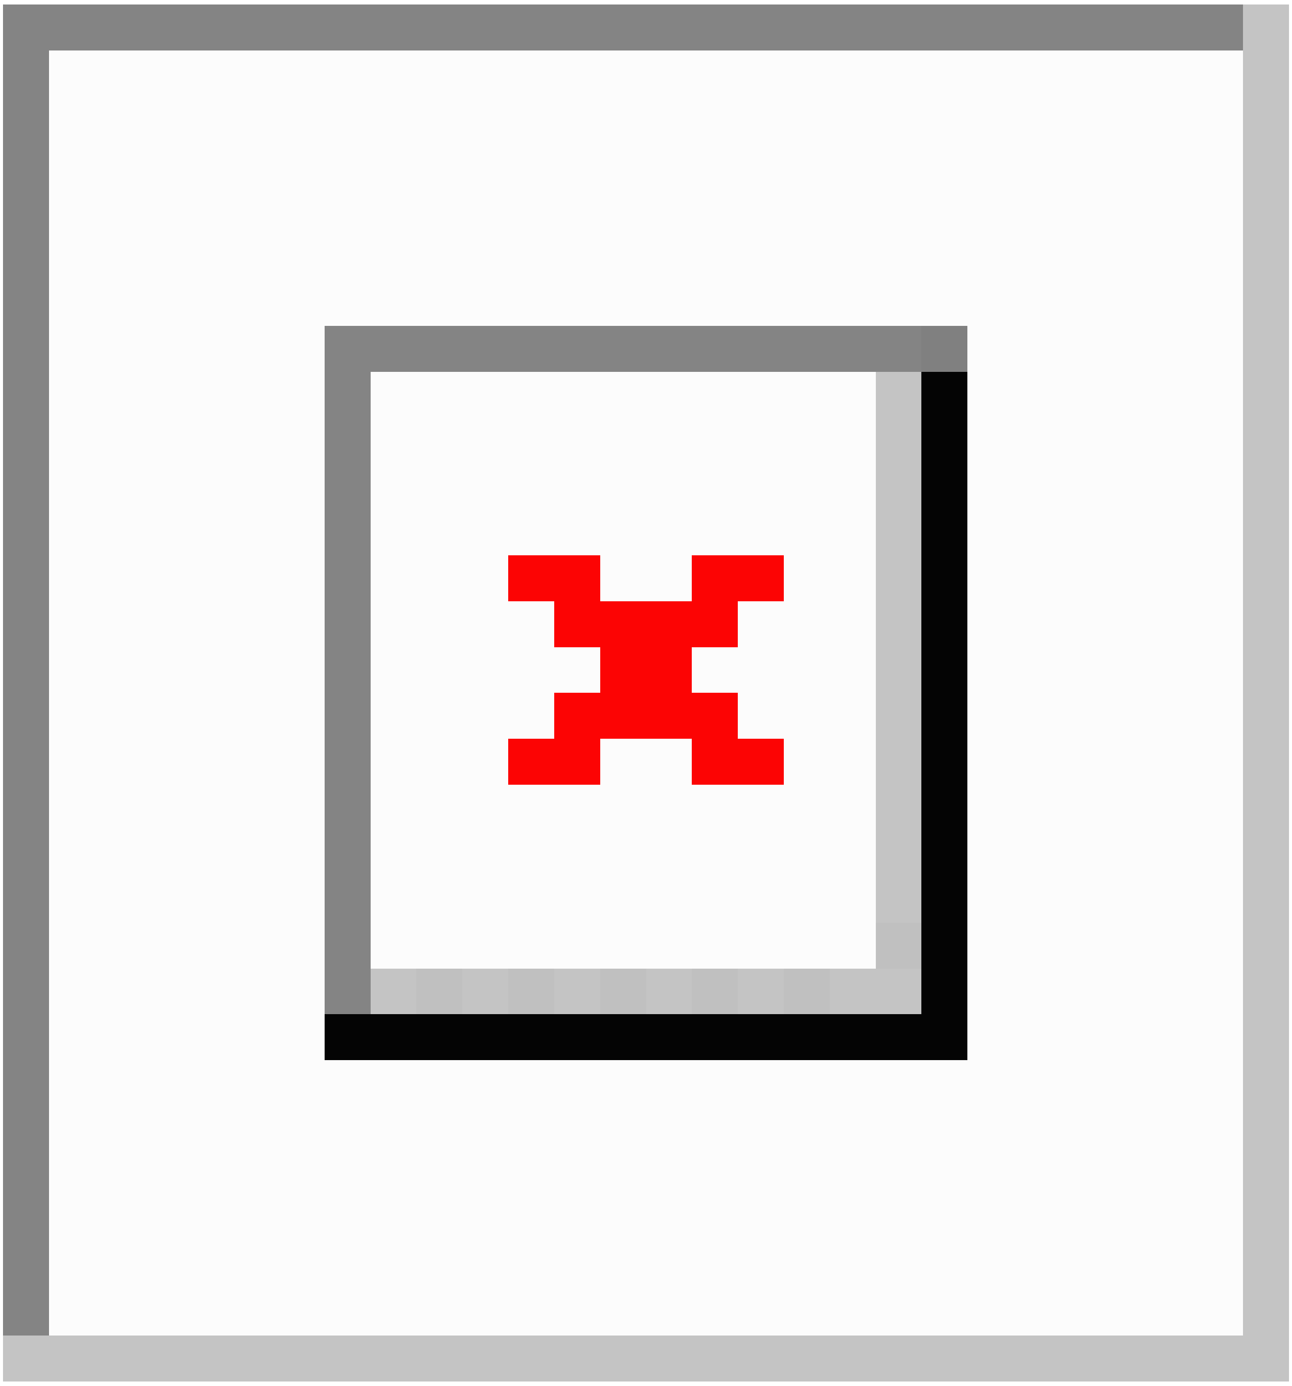
Figure 5. Learning objectives and corresponding game elements in the game. FTC: flattening the curve; GDP: gross domestic product; ICU: intensive care unit.



Infection Model

The modified SEIHR model implemented in the game consists of distinct stages: Susceptible (S), Exposed (E, latent period), Infected (I), Hospitalized (H), Recovered (R), and Dead (D) (Figure 6). When a noninfected agent (S) contacts a symptomatic agent (E2 or I1), they enter the latent period (E) based on infection probability. After a certain duration, the infection progresses to symptomatic mild stage (I1).

Figure 6. In-game description of the modified SEIHR model. ICU: intensive care unit; SEIHR: Susceptible-Exposed-Infectious-Hospitalized-Recovered.



In the earlier exposed phase (E1), agents do not have symptoms and are not infectious. Over time, they change to an exposed state with infectiousness (E2). Infected individuals are categorized into 2 groups based on the severity of symptoms. Mild patients (I1) can infect others and eventually recover (R) after a designated period. Some patients may advance to severe cases (I2) based on predefined probabilities linked to disease characteristics and age. If an ICU is available, severe patients can be isolated (H) and recover (R); if ICU isolation is not possible, these patients face mortality (D). The initial ICU bed capacity is limited and treatment in the ICU takes a considerable amount of time. Therefore, players are prompted to use their budget to expand ICU capacity. The ages and severity rates of agents in the game are distributed similarly to real-world statistics based on relevant data provided by the Korea Disease Control and Prevention Agency [51] (Table 1).

In addition, we have incorporated various infectious disease scenarios to facilitate a natural understanding of disease characteristics. Table 2 shows the latent and infection period, average infection rate, and morbidity of each disease implemented in the game. The included infectious diseases are COVID-19 and its variants (Delta and Omicron), measles, and the Ebola virus. This allows coverage of a spectrum of infectious diseases, ranging from those with low mortality rates and high infection rates to representative diseases with higher mortality rates and slower transmission.

Table . Population distribution and severe morbidity by age group (based on COVID-19, the default scenario).

	Age range (years)								
	0 - 9	10 - 19	20 - 29	30 - 39	40 - 49	50 - 59	60 - 69	70 - 79	≥80
Distribution, %	8	10	13	13	16	18	13	5	2
Morbidity, %	1.6	1.6	1.6	3.7	3.7	13.4	27	54	54

Table . Infectious disease scenarios and major characteristics.

Disease type	Latent period (days)	Infection period (days)		Infection rate, %	Morbidity, %
	S to E1[a]	I1 to R[b]	I1 to I2[c]		
COVID-19	3 - 4	19	4 - 5	5	12
COVID-19 (Delta variant)	3 - 4	19	4 - 5	13	14
COVID-19 (Omicron variant)	3 - 4	19	4 - 5	58	3
Ebola	1 - 2	18	3 - 4	2	55
Measles	3 - 4	17	2 - 3	17	0

[a]S to E1: Susceptible to Exposed (earlier, noninfectious stage).

[b]I1 to R: Infectious (mild case) to Recovered.

[c]I1 to I2: Infectious (mild case) to Infectious (critical case).

Quarantine Policy Model

Every 7 days, players can choose an appropriate quarantine policy based on the current status of disease spread. In the game, social distancing, travel control, and ICU expansion policies are implemented.

Social distancing policies are implemented based on the "containment and closure" category policies, according to the COVID-19 government response tracker from Oxford [63]. This category includes measures such as school closures, workplace shutdowns, cancellation of public events, restrictions on gatherings, public transport closures, stay-at-home orders, limitations on movement between cities or regions, and restrictions on international travel. As simplified by participants' feedback, the game only incorporates school closures (affecting those under 20 years), workplace shutdowns (affecting those between 20 and 50 years), and lockdowns (affecting all age groups). Although social distancing policies effectively control the spread of infectious diseases, they inevitably reduce overall public mobility, leading to a decrease in economic activity. This can constrain budgets for other control measures and potentially slow vaccine development. Consequently, players must carefully consider the long-term trade-offs when implementing social distancing strategies.

With the travel control policy, players can build walls at the boundaries of selected areas to prevent travel across those boundaries. This effectively restricts people within a zone from traveling to another zone, but it requires a weekly budget to maintain the walls. Furthermore, the policy has been designed to not entirely restrict travel between zones in order to accommodate for the restrictions of the real-world travel control policy. As a result, the effectiveness of the policy may vary depending on the pattern of infection spread. This requires players to carefully consider the spatial distribution of infections and strategically implement this policy to optimize timing and location to maximize impact.

ICU expansion permanently increases the number of available ICU beds through budget spending. The concept of flattening the curve is implemented through this. Players should slow the spread of infectious diseases through quarantine measures while continuously investing in ICUs to increase medical capacity and reduce deaths [64]. Expanding ICU capacity is crucial but expensive. As disease transmission stabilizes and ICU demand declines, some additional beds may become underutilized. This highlights the need for players to consider the long-term cost-effectiveness of such investments.

Economic Model

Although quarantine policies prove effective in curtailing the spread of infectious diseases, they carry the side effect of impeding economic activities [56,57]. To enhance learners' understanding of how quarantine policies impact a community's economy, we integrated a GDP-based economic module into the game. Economic activity within the game was designed to be correlated with the movement speed of agents, setting GDP as the total accumulation of economic activities over a week (ie, the sum of movement distances). The movement speed of each agent is contingent on factors such as age group, quarantine policies, and the prevailing infection situation. The economically active population aged 20 - 59 years moves at a faster pace than other age groups, with mild patients experiencing a 10% reduction in movement speed and severe patients being unable to move until recovery.

GDP functions as an indicator gauging the overall level of local economic activity, and players are allocated a budget each month proportional to the GDP of the preceding 4 weeks. This budget is essential for implementing travel control policies and expanding ICU capacity. Users face dilemmas, pondering whether to accept economic losses through stringent social distancing policies to slow the spread of infection or to mitigate economic damage through lenient social distancing policies while securing crucial budgets for augmenting ICU capacity.

Game Development With PD

To enhance participants' engagement and motivation when playing the serious game, we employed PD and analyzed learner feedback based on the DPE framework [33]. All 16 students in the class took part in the PD process. Throughout the activities, participants played the game, shared their experiences and opinions, and provided recommendations, which were mostly incorporated into the final version. Following the DPE framework, participants' feedback was categorized according to subcomponents of serious game design: learning, storytelling, gameplay, and user experience (Table 3).

Table . Participants' key feedback and related implementation examples.

User feedback by Design, Play, and Experience layers		In-game implementation
Learning		
	• Users can understand the dynamics of disease spread through visual simulations. • Learning about the differences in disease spread patterns based on virus characteristics. • Understanding the necessity and effectiveness of various public health policies. • Balancing adjustments are needed (eg, enhancing the effectiveness of social distancing policies).	Game parameters such as default movement speed, maximum impact of social distancing policies, and amount of budget were adjusted to achieve optimal game balance.
Storytelling		
	More scenarios are desired.	Implementation of various infectious diseases beyond COVID-19.
	Immersion in the narrative is hindered by the star rating system.	Addition of a vaccine development system to replace the scoring system.
Gameplay		
	New systems like locations and behavior patterns are needed.	Introduction of a 4-zone travel control system.
	There are too many elements requiring complex intervention.	Simplification of policy user interface.
User experience		
	User interface and design improvements are needed.	Design rework and implementation of a speed control feature.
	Lack of guidance on how to use the game (need for a tutorial) and need to add feedback elements like alerts and pop-ups.	Pop-ups for budget system and implementation of Key Facts.

In the learning component, participants generally agreed that the game enabled them to learn the intended learning objectives. However, in the initial version, feedback arose regarding the game's balance, causing issues like uncontrollable spread of disease or overly strong social distancing effects. To address these problems and enhance learning, efforts were made to balance the game, including lowering default agent movement speed and reducing the maximum impact of social distancing policies on movement speed.

Regarding the storytelling component, even though there was no direct narrative or story in the game, participants immersed themselves in the game by adopting the background narrative of being the "public health manager." Feedback suggested enhancing the narrative, leading to the introduction of various types of infectious disease scenarios that players could select at the beginning of the game.

In addition, the initial version of the game ended when the infectious disease was eradicated, and game results were rated on a 10-star scale based on cumulative confirmed cases (up to 1 star), deaths (up to 4), economic activity levels (up to 3), and remaining budget (up to 2). However, this star rating system impeded the players' empathy and made gameplay time too long. Further, a fairness issue [65] arose as players prioritized economic activity over managing deaths to gain more stars. To solve these problems, a new clear condition (vaccine development) was introduced. The progress of vaccine development increases each week based on the number of survivors without severe symptoms and the amount of GDP. Players can expedite vaccine development by focusing on minimizing casualties and economic damage. The final version of the game ends when the vaccine development progress reaches 100% or a year passes.

Regarding the gameplay components, participants mainly proposed new features such as events in new locations, gatherings, and activities in specific areas of the game. However, considering the potential excessive influence of these features on the game's outcomes, seen as too random, we have introduced a new social distancing policy, the travel control system (Figure 7). In the later stages of the PD process, after more game features had been implemented, opinions regarding the simplification and improvement of existing features were added. For example, players were originally able to manually set the reduction in movement speed for each age group at each policy stage and activate the policies. However, as players perceived this feature to be too complex and began to underutilize it, we opted for a user interface (UI) enhancement, replacing the user customization feature with a simpler on/off mechanism for policy activation (Figure 8).

Figure 7. (A) The image illustrates the implementation of travel control measures, where red lines indicate blocked movement between zones. (B) An in-game description of travel control measures.

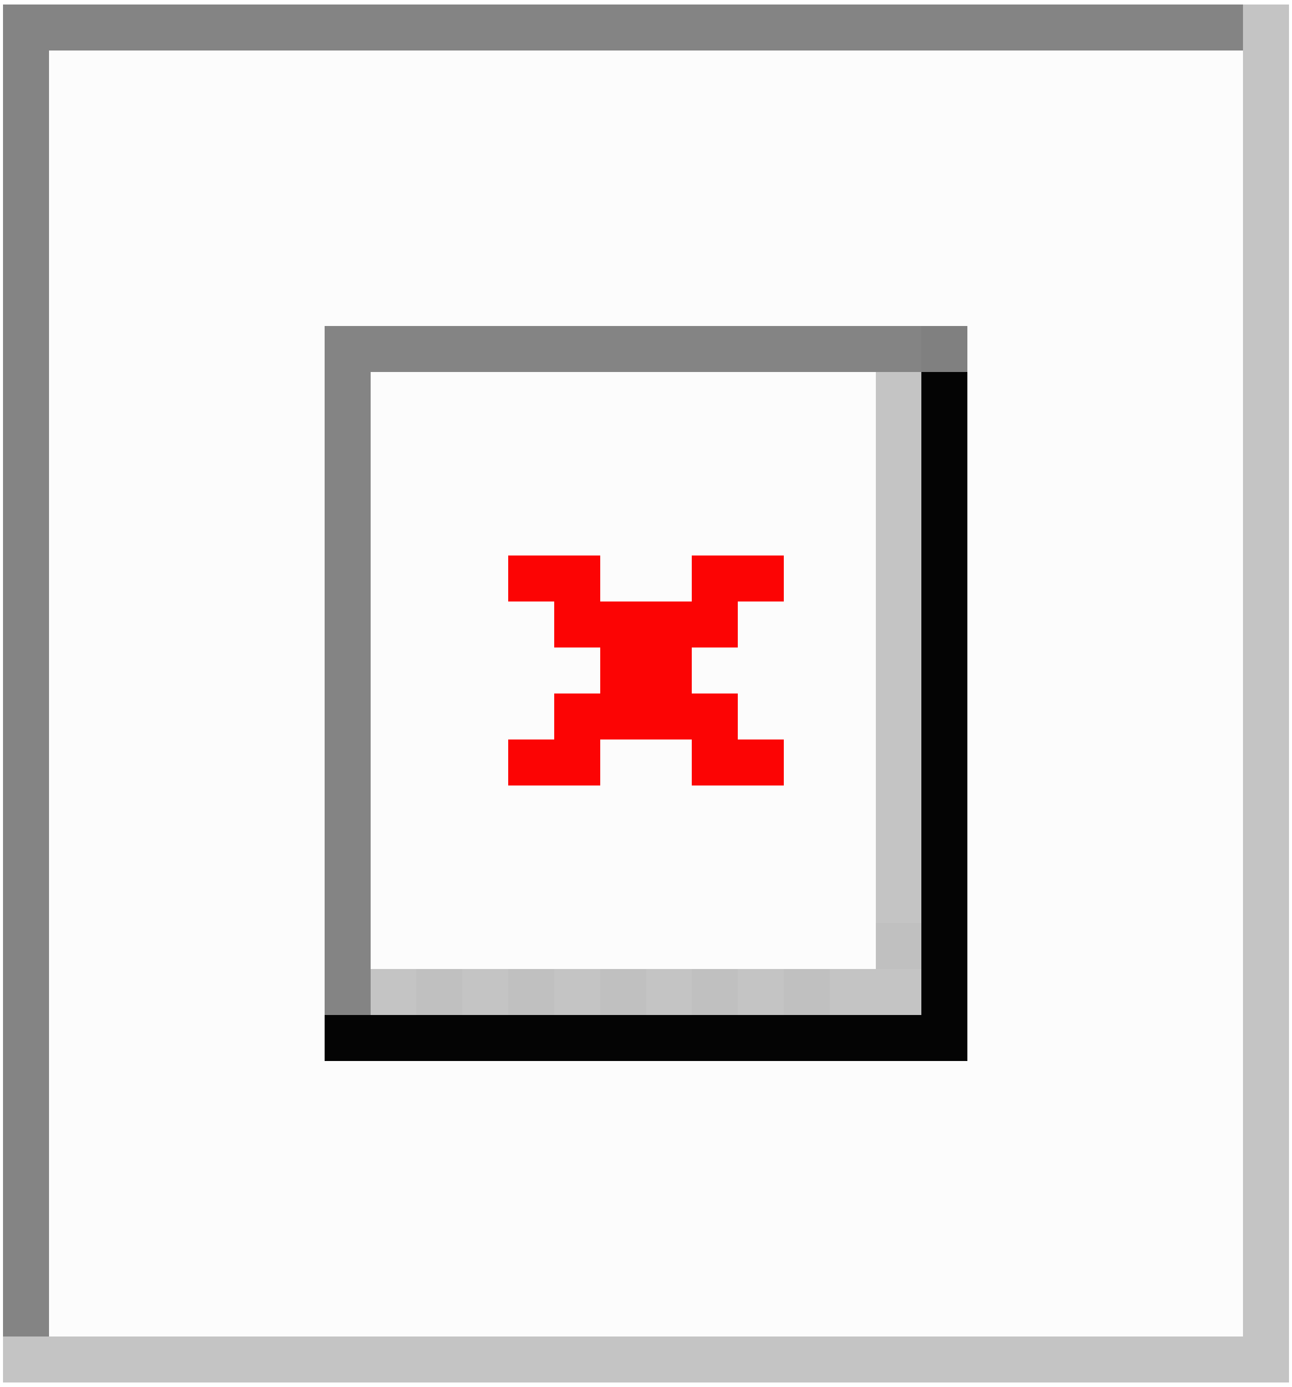


Figure 8. Example changes to improve UI for the social distancing policy. (A) The earlier version UI. (B) The final version UI. UI: user interface.

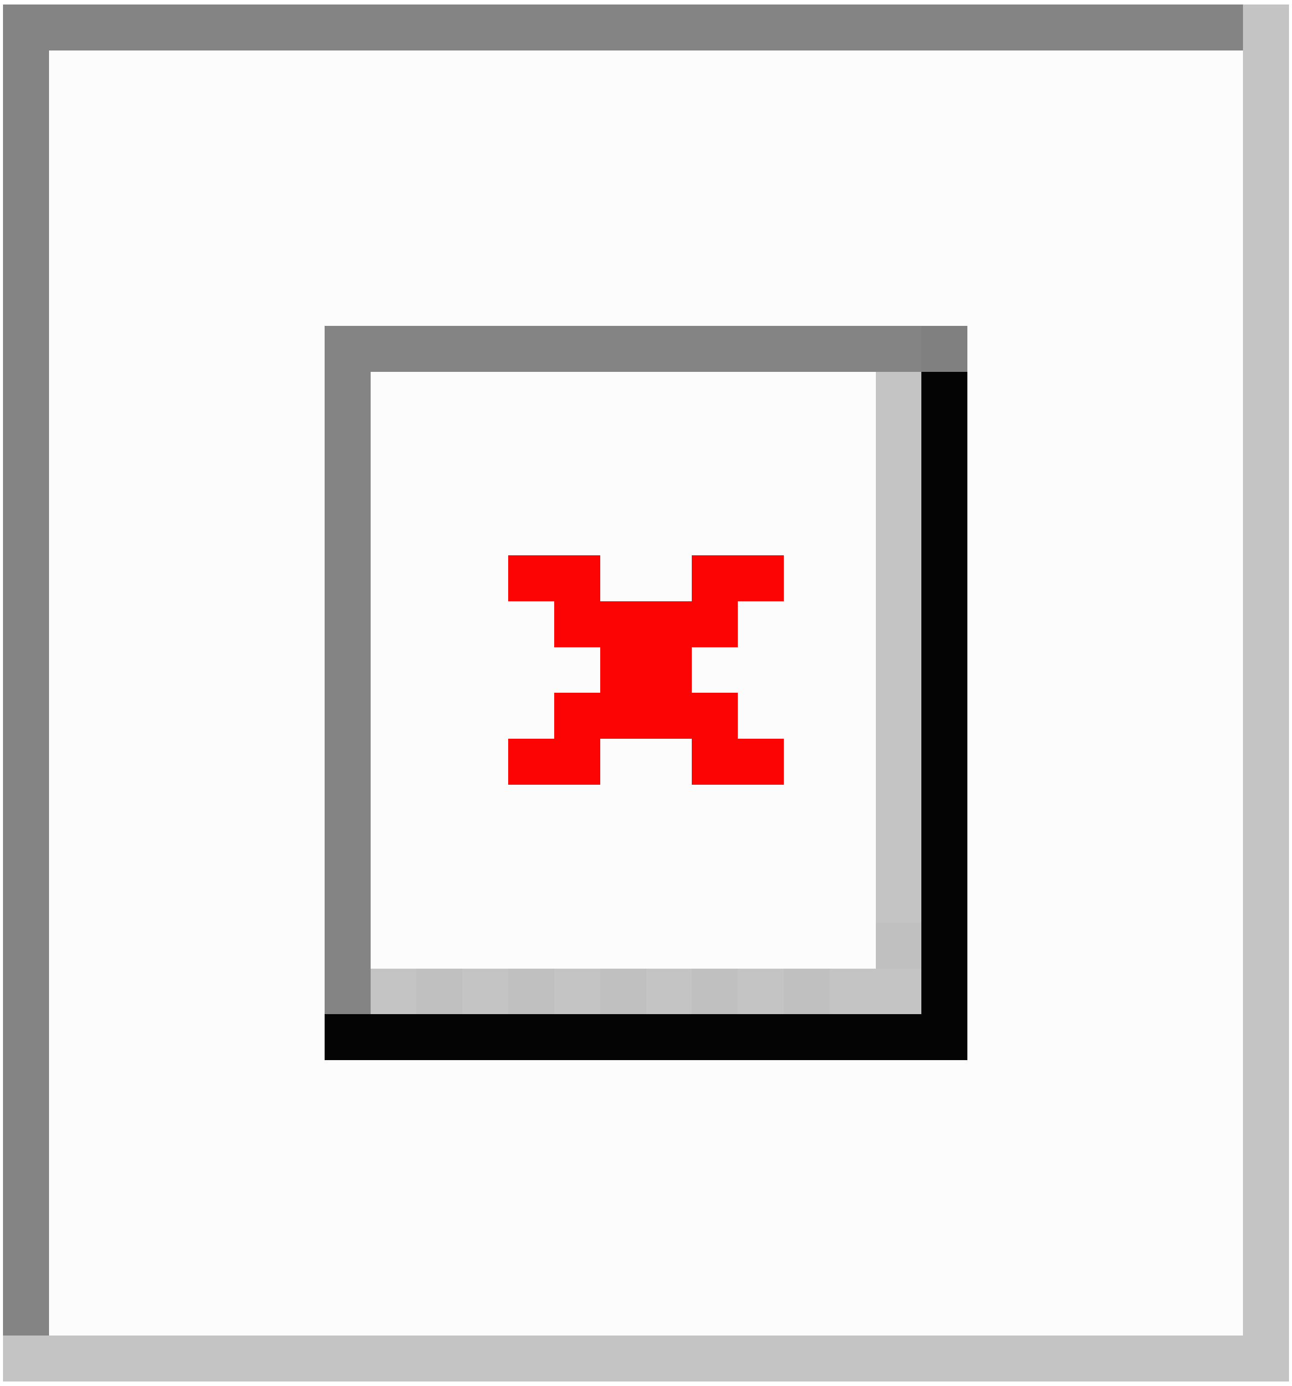

In terms of the user experience component, there were suggestions for improving the game's UI and design, as well as incorporating in-game feedback and tutorials. Responding to participants' opinions, we collaborated with design experts to completely rework the game design (Figure 9). To prevent monotony during repeated gameplay, a speed-up function was added, allowing users to accelerate simulation progress by up to 8 times. In response to feedback, budget notifications and pop-up alerts for budget shortages were implemented. Additionally, to assist new players in understanding and learning the game, we introduced a Key Facts tab providing essential information. Clicking on hint icons placed near elements requiring explanation adds the corresponding information to the Key Facts tab, allowing players to access explanations whenever needed (Figure 10).

Figure 9. Results of overall design improvements. (A) The initial version. (B) The final version of the game. GDP: gross domestic product; ICU: intensive care unit.

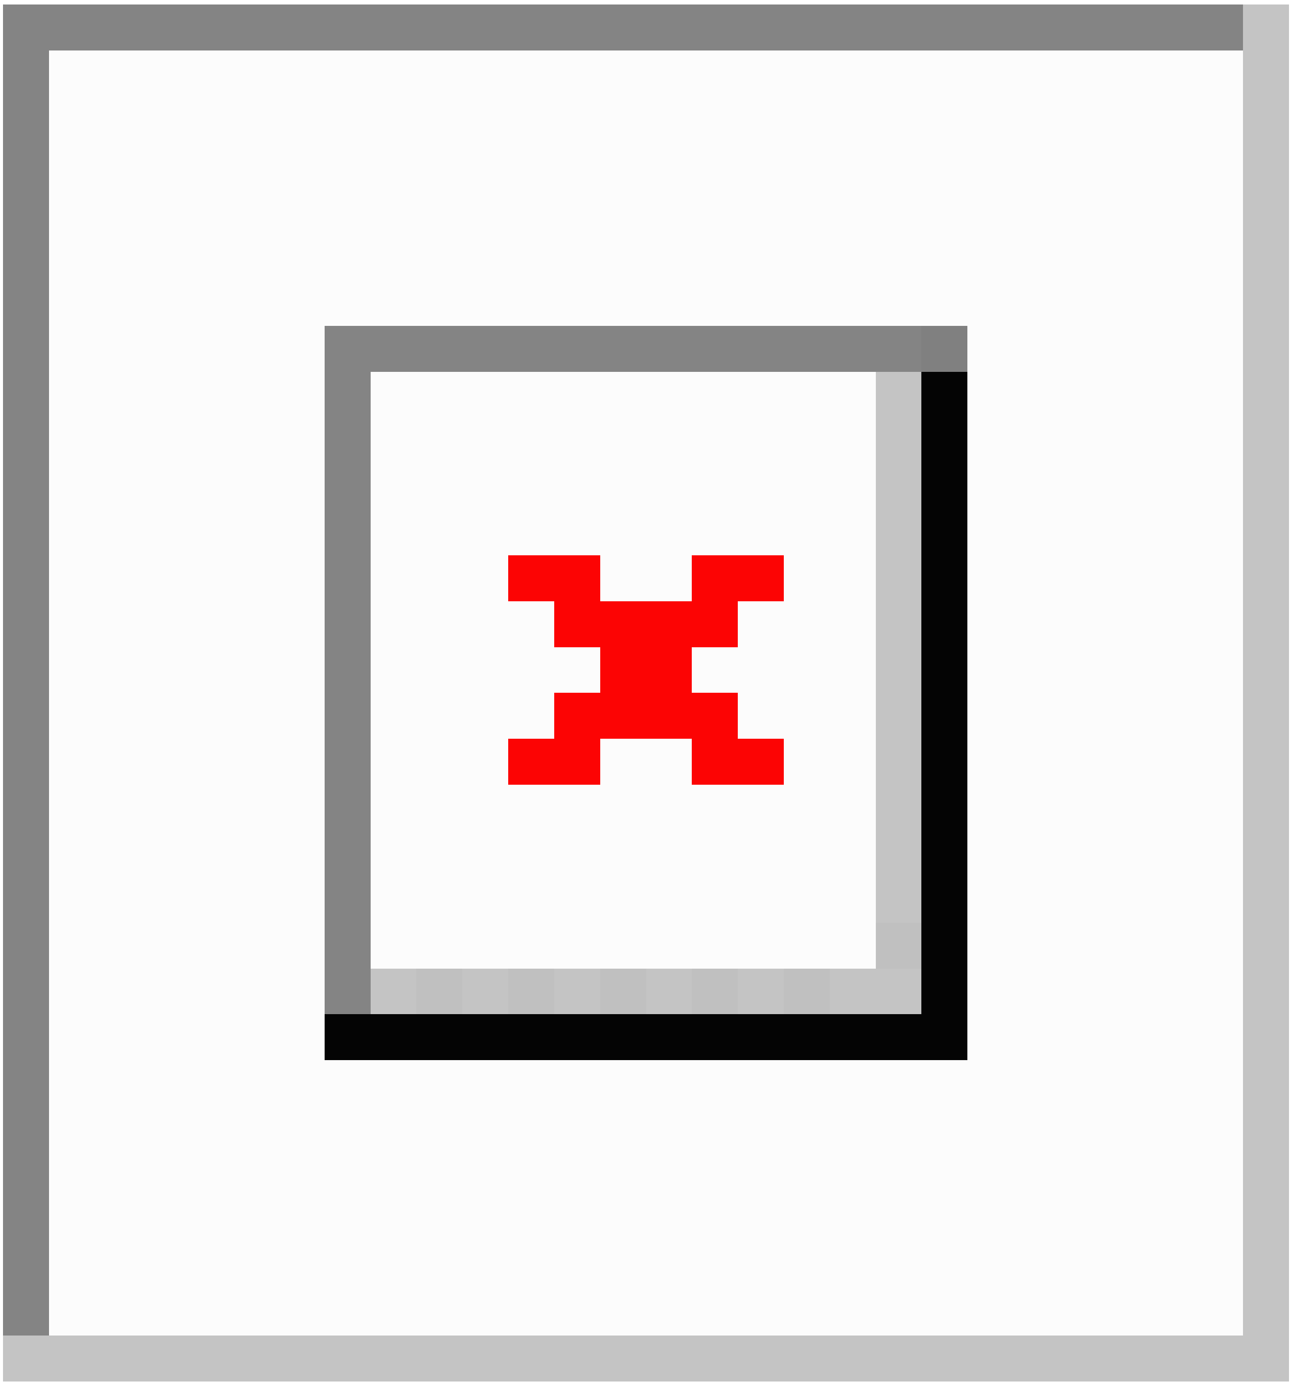

Figure 10. Overview of the Key Facts system. (A) When a player clicks a hint icon, (B) a message appears at the top, and (C) the Key Facts icon shows the count of newly discovered hints.

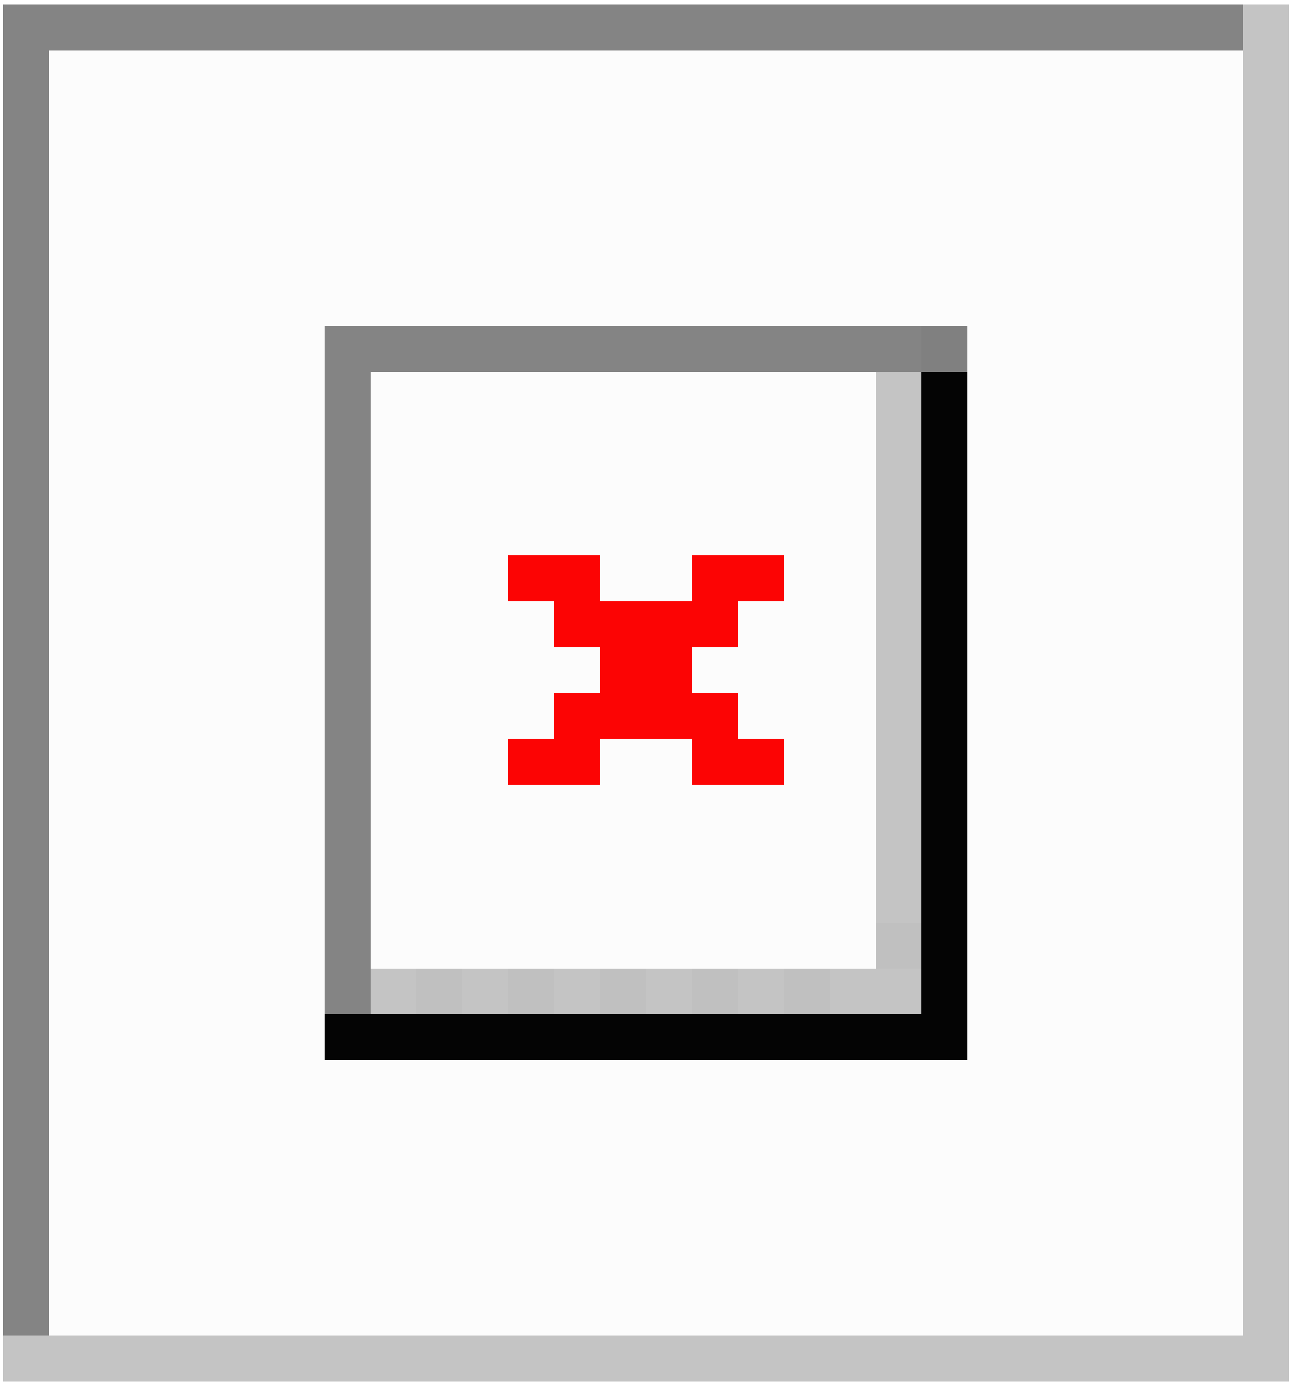

Game Evaluation

To assess if the game achieved its educational goals, we conducted surveys with the participants. The surveys measured the game's educational impact and its influence on participants' motivation to learn. In the earlier stage of PD, the first survey was conducted to measure participants' satisfaction with the initial version of the game. The second survey was conducted at a later stage and focused on examining participants' final evaluations of the game. Table 4 shows the descriptive statistics of the survey constructs.

Wilcoxon signed-rank tests were performed to examine the changes in participants' satisfaction between the 2 surveys. Although participants reported higher satisfaction in the second survey, the difference was not statistically significant (Z=−1.890, P=.06).

Participants also gave an overall positive evaluation of the game-based learning experience, with average scores of 6.19 and 6.06 for perceived learning and enjoyment, respectively. The perceived usefulness and ease of use, variables to examine the technical acceptance of FTC, were also evaluated positively, with an average of 5.75 and 5.63, respectively.

Table . Descriptive statistics of survey items (N=16).

Construct		Rating range	Values, mean (SD)
First survey			
	Satisfaction	1 - 4	2.94 (0.574)
Second survey			
	Satisfaction	1 - 4	3.25 (0.447)
	Perceived learning	1 - 7	6.19 (0.544)
	Enjoyment	1 - 7	6.06 (0.755)
	Usefulness	1 - 7	5.75 (0.848)
	Ease of use	1 - 7	5.63 (0.717)

Discussion

Principal Findings

Since the COVID-19 outbreak began in 2019, there has been a proliferation of educational materials on various preventive measures for infectious diseases. However, there remains a need for educational resources that facilitate a fundamental understanding of infectious diseases and quarantine policies. This study presents the development and design process of a quarantine policy education game ("Flattening the Curve"). The game serves as a comprehensive educational simulation, allowing users to learn about the characteristics of infectious diseases, the stages of transmission, the necessity and effectiveness of quarantine policies, and the crucial balance between these policies and economic considerations. Ultimately, the game aims to enhance learners' understanding of the concept of "flattening the curve."

The application of the SERES framework played a pivotal role in achieving a scientifically sound and educationally effective game [25]. Drawing insights from prior research, the scientific and design foundations of the SERES framework were found to be effective in developing health-related serious games [17,66]. Building on these foundations, this study effectively developed various learning components within the game, such as the infection model, social distancing model, and economic model.

This study shows that both the SERES framework and the PD process can be used simultaneously and interactively during the serious game development process. The effectiveness of education in an e-learning environment is highly dependent on the learner's motivation to learn [67], and an appropriate PD process during serious game development can lead to higher user satisfaction, which is essential for learner motivation [26,68]. The PD process was incorporated into the development of FTC to enhance the overall quality of the game and ensure learner engagement [69]. Participant feedback, categorized into the domains of learning, storytelling, gameplay, and user experience based on the DPE framework, guided the game's improvement and detailed development direction [33].

As the survey results showed, the final game received positive evaluations from participants. The PD activities made the serious game more enjoyable and satisfactory and contributed to the enhancement of the game's richness and user enjoyment.

Limitations and Further Research

Despite our efforts to increase the game's appeal to younger learners through design modifications guided by feedback from the PD process, this study has several limitations regarding its participants and evaluations. A comprehensive analysis of the game's learning effects was not conducted. Although validating the effectiveness of educational games is crucial, this study did not measure quantifiable learning outcomes, such as changes in knowledge or attitudes. Due to the nature of the PD process, participants engaged in continuous gameplay and provided feedback throughout a semester, posing challenges in evaluating the knowledge acquisition effects solely through gameplay. Consequently, the current evaluation primarily focused on qualitative assessments of learners' perceptions of the learning content.

Future research should target learners across various age groups, including children and adolescents. Measuring changes in knowledge related to infectious diseases and shifts in attitudes toward quarantine policies before and after gameplay can offer a more comprehensive evaluation of the learning effects of the FTC game. Additionally, we propose to evaluate the game with various game mechanics, such as difficulty and enjoyment. Investigating the relationship between game evaluations and learning effects will be instrumental in gaining a deeper understanding of the game's impact on learners.

Although not specifically addressed in this study, we have experimentally developed various multiplayer modes to respond to participant feedback and assessed their impact on learner engagement. Consistent with prior research [70], participants found the game more engaging in multiplayer mode than in single-player mode. Subsequent research could delve into how multiplayer mode can make serious games better, highlighting the effects of different gameplay modes on learning outcomes and immersion. This underscores the importance of sustained research and development efforts in the serious game domain, particularly those focused on enhancing learning experiences through innovative gameplay features.

Conclusions

"Flattening the Curve," a serious game designed to promote understanding of epidemic models and quarantine policies, was successfully developed by applying the SERES framework and the PD process.

The developed game is now publicly accessible online, allowing anyone to play [71]. The game is not only designed to educate about COVID-19–related quarantine policies but also serves broader educational purposes related to various types of infectious diseases. The game's source code is accessible to everyone, facilitating diverse educational applications and modifications to serve various research and educational objectives. The source code for the game is provided in a GitHub repository [72]. Resources are available under the license mentioned in the provided link. The authors welcome requests for additional information regarding the material presented in this paper.

Acknowledgments

This paper was financially supported by the Human Resource Development Project in Disaster Management and the Development of Life Safety Prevention Service Technology (2019-MOIS34-001 [RS-2019-ND618031]) of the Korea Ministry of the Interior and Safety.

Data Availability

As mentioned above, the source code of the game is provided in a GitHub repository [72]. The datasets generated during this study, including Korean-language data (transcripts and written assignments), are available from the corresponding author on reasonable request.

Authors' Contributions

JBC led the conceptualization, with MK and BJK supporting conceptualization. BJK led data curation, with support from MK. BJK did the formal analysis. JBC acquired funding and provided project administration, supervision, and resources. BJK led the investigation with support from MK and JBC. JBC led the development of the methodology with support from MK and BJK. MK was responsible for the software. BJK led validation with support from MK. MK was responsible for visualization, with support from BJK. BJK and MK wrote, reviewed, and edited the original draft with support from JBC.

Conflicts of Interest

None declared.

Using Games to Simulate Medication Adherence and Nonadherence: Laboratory Experiment in Gamified Behavioral Simulation

Abstract

Background: Medical nonadherence is a significant problem associated with worse clinical outcomes, higher downstream rehospitalization rates, and a higher use of resources. To improve medication adherence, it is vital for researchers and practitioners to have a solid theoretical understanding of what interventions are likely to work. To achieve this understanding, we propose that researchers should focus on creating small-scale laboratory analogs to the larger real-world setting and determine what interventions, such as nudges or incentives, work to change behavior in the laboratory. To do this, we took inspiration from the literature on serious games and gamification and experimental economics. We call our approach "gamified behavioral simulation." In this paper, we modeled everyday life as the state of being engaged in a simple but addictive game, illness as being interruptions to the functionality of that game, treatment as being a series of actions that can be taken to prevent or mitigate those interruptions, and adherence as sticking to a prescribed rule for the application of those actions.

Objective: This study carries out a behavioral diagnosis of the medication adherence problem through a theoretically informed framework and then develops the gamified behavioral modeling approach to simulate medication nonadherence.

Methods: A laboratory experiment was conducted using a modified popular and addictive open-source video game called "2048," which created an abstract model for the medication adherence behavior observed in real life. In total, 509 participants were assigned to the control and 4 intervention groups ("incentive" group, "reminder" group, "commitment device" group, and "elongated duration for symptoms" group).

Results: The results of the modeling experiment showed that having theoretically informed interventions can increase the likelihood for them to be successful. In particular, there is evidence that the use of reminders improves the medication adherence rates for patients, and the same result was found in the modeling experiment, as they improved adherence significantly by 23% (95% CI −33.97% to −11.72%; *P*<.001). However, providing an incentive did not improve the adherence rate. We also tested the use of commitment devices, which, in line with real-world evidence, did not improve adherence rates. The fourth treatment tested elongated duration for symptoms, which attempted to show the power of modeling experiments where we test a what-if scenario that is extremely difficult to test in a real setting. The results indicated that if symptoms last longer, people did not adhere more to their medication regimen.

Conclusions: Gamified behavioral simulation is a useful tool to explain real health behaviors and help in identifying which interventions are most likely to work in a randomized trial.

Introduction

Overview

Medication adherence is the extent to which the patient's behavior matches the agreed recommendations from the prescriber. There is consistent evidence that regardless of what is being treated, nonadherence is associated with worse clinical outcomes and higher downstream rehospitalization rates [1]. Yet, several reviews have found that medication adherence among patients is low, especially in low-income countries [1-3]. In the United States, for example, 51% of patients with hypertension adhere to their medication, but the corresponding numbers in Gambia, Seychelles, and China are 27%, 26%, and 43%, respectively [4-8]. Even in the developed world, medication nonadherence is expensive. The annual cost to the

UK government has been estimated at £150 million (approximately US $270 million in 2005); for the United States, this figure is over US $1 billion [3].

The cause of medication nonadherence varies among patients and can be categorized as intentional or unintentional [9]. Intentional nonadherence involves patients who decide consciously not to take medication as instructed, based on perceptions, feelings, or beliefs [10]. Unintentional nonadherence occurs when the patient wants to take their medication as instructed but fails to do so. The most common factors associated with nonadherence include forgetfulness (50%), having other medications to take (20%), and being symptom-free (20%) [11]. To the extent that nonadherence is unintentional, patients are likely to welcome any nudge that helps them adhere to their doctor's recommendations.

New and innovative strategies are essential to successfully improve patient adherence to treatment. One potentially effective strategy for understanding patient medication adherence is the use of serious games and gamification [12] or the introduction of gaming elements into the medication experience. Games motivate users into engaging in an activity with a higher intensity and duration [13]. Game elements are activities, behaviors, and mechanisms designers incorporate into a specific context to create a gameful experience [13]. Introducing gaming elements into a nongaming context has the potential to transform routine tasks into more enjoyable and motivating experiences [14]. The aim of this study is to conduct a behavioral diagnosis of medication adherence issues using a theoretically informed framework and then to design, implement, and assess a game-based setting for simulating nonadherence behavior.

A range of studies have explored the use of games and technology (mainly via mobile health apps) to understand and improve treatment adherence. Tran et al [15] found that these features can lead to improved or sustained medication adherence but noted significant heterogeneity in patient populations and methodologies. de Vette et al [16] highlighted the potential of games to engage older people in telemedicine, while Brown et al [17] called for further research to understand the impact of game features on program adherence in web-based interventions for mental health. These studies collectively underscore the potential of games and incentives in improving medication adherence.

This paper takes inspiration from the literature on serious games and gamification and experimental economics. We call our approach "gamified behavioral simulation." We model everyday life as the state of being engaged in a simple but addictive game, illness as being interruptions to the functionality of that game, treatment as being a series of actions that can be taken to prevent or mitigate those interruptions, and adherence as sticking to a prescribed rule for the application of those actions. As far as we are aware, no previous research has addressed whether serious games can be used to model (simulate) medication adherence behavior and test the effectiveness of interventions to improve such adherence. This is a crucial gap in the literature that our study addresses.

Background

Existing literature indicates that interventions to improve medication adherence have had mixed results [3,8]. The Medical Research Council proposes that the development of a behavior change intervention should follow the same cycle as drug development: (1) a theory behind the design of behavioral intervention; (2) followed by modeling of the problem or behavior; and (3) finally, a randomized controlled trial (RCT) and implementation of the intervention [18].

Interventions developed to bring about behavior change often offer limited practical value, as they lack a theoretical basis for their selection and development [19]. The Medical Research Council proposes that an important early task for a researcher is to develop a theoretical understanding of the underlying process and constructs that might bring about behavior change. This helps in clearly understanding how successful interventions have had their effect, that is, which behavior change processes can be attributed to the observed change. A theoretical underpinning further allows the researcher to argue for the selection of a particular intervention [18].

The Medical Research Council proposed that this "theory" stage should be followed by a "modeling" stage, which can be considered as the equivalent to "testing with mice" in the drug development cycle. Modeling allows the researcher to investigate and identify the exact mechanisms that are bringing about the behavior change. It makes possible the study of isolated effects of different interventions. Modeling thus allows the researcher to make complex phenomena manageable and create knowledge about the underlying mechanisms of behavior change that might be quite difficult to uncover otherwise [18]. It is only once a clear understanding of what works has been achieved through the modeling stage that an RCT should be carried out to empirically test the intervention.

In this study, we focus on the "modeling" stage for developing behavior change interventions to increase patient's adherence to antibiotic medication. It is common in behavioral science and economics to model real-life behaviors in a laboratory setting in an attempt to control and make tractable the phenomenon that the researcher is interested in investigating. However, introducing this modeling approach in the development of complex interventions is not commonly found in the health behavior change literature [19]. We argue that using gamified behavioral simulation to first model treatment behavior can provide important information about the choice and design of the behavior change intervention to be tested in an RCT in a short time with a low cost.

Our experimental model for the nonadherent behavior in patients taking antibiotics was inspired by the conceptual approach developed by Kessler and Roth [20]. They used an abstract experimental interaction to model the effectiveness of the priority rule in increasing the registration of organ donors. An organ allocation policy that prioritizes registered donors on waiting lists was found to significantly boost donor registration. Their setting did not involve actual organ donation decisions and neither did they use any organ donation terminology during the experiment. However, they imposed real (monetary) costs to correspond to the analogous costs associated with decisions to donate or receive an organ. Their results showed that the priority rule condition had a significant positive impact on their laboratory-based "organ donation–like" decisions, and they used this to make a strong case in their paper to introduce the priority rule in the organ donation policy present in the United States. Subsequent work in the field indeed suggested that this laboratory method, designed without making any direct reference to organ donation, predicted organ donation attitudes and preferences [21] and even became the basis for policy decisions in at least 1 country [22].

We adopted a similar approach. The aim of this study was to develop an abstract experimental task that can capture the key elements of a real-world setting and thus simulate the nonadherence behavior of the patients taking antibiotic medication. At the heart of the task was a "game," which enabled us to make the experiment engaging and to incentivize behavior. This simulation served as a platform to test multiple interventions to positively increase the target behavior.

Our research question addresses a significant challenge in gamification technology: whether gamified behavioral modeling is a useful tool to explain real health behaviors and help in identifying which interventions are most likely to work in the real-world [23,24]. This challenge stems from the need to validate that behaviors observed within a gamified environment accurately reflect those in real-world settings. Additionally, it ensures that the motivational elements used in serious games are effective in driving the desired health behaviors and can be predictive of the outcomes of interventions in randomized trials. Addressing this challenge is crucial for the advancement of gamified applications in health-related fields, where the ultimate goal is to positively influence health outcomes and behaviors.

To address this question, we examined a range of interventions—those that have yielded both successful and unsuccessful outcomes in real-world trials—and assessed whether our gamified behavioral simulation can mirror these varied patterns of results. Therefore, our hypothesis was that our gamified behavioral simulation can accurately replicate these results, which implies that it would be a useful tool for predicting the success of interventions in the field.

Note that this approach differs from traditional methods to develop and test medication adherence interventions, which usually involve understanding barriers to action (adherence) and designing field trials to test interventions that address those behavior change challenges [25-27]. These interventions include patient education, medication regimen management, clinical pharmacist consultation, cognitive behavioral therapies, incentives, and various technology-based intervention and measurement components such as medication-taking reminders, support messages, and adherence measurement methods (eg, electronic drug monitors [pill bottles], sensor systems, and proximity sensing) [26]. Such field trials are costly and often cannot test every possible intervention strategy. Thus, evaluating our gaming methodology is essential, as it allows us to explore certain hypotheses about medication adherence within a controlled laboratory environment, where actual medication decisions are not involved. While not all aspects of medication adherence can be abstracted for study, there are critical elements of the adherence decision process that cannot be consistently manipulated in real-world settings, yet are amenable to manipulation in a laboratory setting (such as, different incentive schemes or elongated duration for symptoms).

Methods

Experiment Design

The laboratory experiments were conducted in December 2015 by Gallup Pakistan at 2 laboratories in Islamabad and Karachi. The laboratory experiments involved using a (then) popular and addictive open-source video game called "2048." The game's aim is to move numbered tiles in such a way that the total adds up to 2048 (Figure S1 in Multimedia Appendix 1).

The original 2048 game was modified to create an abstract model for the medication adherence behavior observed in real life. The game is the analog of "everyday life."

Participant Recruitment

The sample (N=509; n=305, 60% male and n=204, 40% female) was recruited through Gallup Pakistan. They were screened on the basis of whether they were able to browse on the internet, as the laboratory experiments requested to play a computer game (each of the control and treatment groups had the same representative proportions). Gallup Pakistan provided transport facilities to any participants who requested it. This was especially the case with female participants, as it was quite difficult to recruit them otherwise. If necessary, the timing of running the experiment was adjusted to accommodate participants after office hours. All participants provided written informed consent.

Procedure

The participants were asked to open the original 2048 game tab and practice for 10 minutes. At the end of the practice round, each participant was asked to close the original 2048 game tab and was directed to open an instruction video tab. The instructional video in Urdu (the national language of Pakistan) was made following a number of pilot tests (Multimedia Appendix 1) and extensive feedback from participants. It was recorded using CamStudio (Rendersoft Development). The instructional video explained in detail how to begin playing the experimental game and gave a demo of the experimental game. Three videos were made. The video for the control group was also used for the "commitment device" treatment condition and the "elongated duration for symptoms" treatment condition. The content of the "incentive" and "reminder" videos were the same except for some condition-specific information. Once the participants were finished watching the instructional video, they were asked to begin the experimental game.

The total duration of the game part of the experiment was 14 minutes and 30 seconds, and the participants were instructed to enter the code every minute or 14 times in total. The 14 code entries simulated a typical 7-day antibiotic medication course where patients are prescribed to take the pill twice a day with roughly 12-hour intervals. However, the inclusion of the initial practice rounds, the instruction video, and the payment process brought the whole task to 30 minutes on average.

Control Condition

When participants started the game, after the instructional video, the screen was blurred, making it very difficult for them to play the game. This blurriness simulated the onset of illness. To simulate the use of medication, participants were provided with a code, which they were required to enter every minute to clear the screen. The screen became clearer each time the code was entered. However, halfway through the game, the screen remained clear even though the participants were still expected to enter the code. If the code was not entered, however, there was a chance of "relapse," and the screen became blurry again.

As an analog to the pill pack, a pill counter was displayed on the left of the screen, showing how many times the code had been entered and how many times remained. Participants received a total of 14 opportunities to enter the code correctly, 1 every minute. If participants failed to adhere to this regimen, then, after the 14 opportunities, their codes become ineffective. This corresponded to the cost of forgetting to take one's medication. On the top left corner of the screen, a timer was displayed with the time elapsed since the start of the game. The timer was there to assist the participants in keeping track of time.

The show-up fee was Rs 80 (£0.50, approximately US $0.77 in 2015), and it was already included in the earnings; participants started the game with a score of 0 and earnings of Rs 80 (£0.50, approximately US $0.77 in 2015). Participants were rewarded on how well they scored in the 2048 game. The maximum money that participants could earn was Rs 500 (approximately £3 or US $4.59 in 2015). The final score and earning of the participant showed up on the screen along with their participant number, which served as an ID.

Participants were allowed to play the game as many times as possible during the duration of the experiment (which was 14 minutes 30 seconds). Once a player had no moves left on the board, a message box popped up on the screen giving the participant an option to restart the game (Multimedia Appendix 1).

To examine whether gamified behavioral modeling is a useful tool to explain real health behaviors and predict which interventions are most likely to work, we examined a range of interventions that have yielded both successful and unsuccessful outcomes in real-world trials, aiming to improve antibiotic medication adherence.

Treatment Condition 1: Incentive

For the "incentive" treatment condition, the design and mechanics of the experiment were exactly the same as the control experiment except that participants were given an incentive of Rs 5 (£0.02, approximately US $0.03 in 2015) every time they entered the correct code on time. This was an extra bonus on top of their usual earnings in the game, and the increment would show up in the earnings box on the top left corner of the screen. In addition, when participants entered the code correctly and on time, a message would flash on the screen informing them that they earned a bonus of Rs 5 (£0.02, approximately US $0.03 in 2015).

The instructional video before the "incentive" version of the game explicitly mentioned the Rs 5 (£0.02, approximately US $0.03 in 2015) bonus that they would earn upon entering the code correctly on time. The video also showed one such instance where the code was entered correctly on time and the earnings increased by Rs 5 (£0.02, approximately US $0.03 in 2015).

Treatment Condition 2: Reminder

For the "reminder" treatment condition, the design and mechanics of the experiment were exactly the same as the control experiment except that a message box would pop up on the screen when it was time to enter the code. The message box informed the participant that it was time to enter the code. This message box would appear in the middle of the board and stay for a few seconds before disappearing.

The instructional video for the "reminder" version of the game explicitly mentioned that a reminder message would show up when it would be time to enter the code. The video also showed one such instance where it was time to enter the code and the message box popped up on the screen.

Treatment Condition 3: Commitment Device

For the "commitment device" treatment condition, the design and mechanics of the experiment were identical to the control experiment except that at the start of the experiment, participants were asked to sign a sticker stating that they committed to entering the code as prescribed. The sticker was then pasted on the laptop they were using to play the experimental game. Participants watched the same instruction video as in the "control" condition.

Treatment Condition 4: Elongated Duration for Symptoms

An additional treatment condition was introduced in which symptoms took twice as long to disappear compared to the control condition. For the "elongated duration for symptoms" treatment condition, the rest of the design and mechanics of the experiment were exactly the same as the control experiment. Participants watched the same instruction video as in the "control" condition.

Ethical Considerations

The study was approved by the University of Warwick's ethics committee (ethical application reference 100/15‐16). All procedures were conducted in accordance with the relevant guidelines and regulations. Strict ethical and legal standards were upheld, ensuring that all personal information was securely stored, treated confidentially, and anonymized. Informed consent was obtained from all participants, permitting the use and publication of their data in this research. Participants received a show-up fee of Rs 80 (approximately US $0.77 in 2015) and had the opportunity to earn up to Rs 500 (approximately £3 or US $4.59 in 2015) based on their performance in the game. Participation in the study was entirely voluntary, and participants retained the right to withdraw at any time without any obligation for further contact from the study staff after withdrawal.

Results

We report results from 509 participants who participated in our laboratory experiment (Figure 1). There were 104 participants in the control group, 106 in the “incentive” group, 97 in the “reminder” group, 102 in the “commitment device” group, and 100 in the “elongated duration for symptoms” group.

Planned comparisons (ANOVA) were carried out to determine significant changes in adherence rates between the control group and treatment groups using the Bonferroni corrections post hoc test. The results showed that the adherence rate differed among the conditions ($F_{4,504}$=10.63; P<.001; n^2_p=0.078). The adherence rate in the control group was 44% (mean 44.16%, SD 27.45%), and similar adherence rates were seen in the “incentive” group (mean 52.02%, SD 29.41%), the “commitment device” group (mean 45.17%, SD 26.50%), and the “elongated duration for symptoms” group (mean 53.57%, SD 29.05%). In particular, the commitment device did not bring any change in the adherence rate compared to the control group (1%, 95% CI −11.99% to 9.98%). In the “incentive” as well as in the “elongated duration for symptoms” treatment group, the adherence rate improved by 8% (95% CI −18.74% to 3.02%) and 10% (95% CI −20.45% to 1.63%), respectively; however, the results were insignificant (*P*=.42 and *P*=.17, respectively). On the contrary, reminders had a different adherence rate (mean 67.01%, SD 27.17%) compared to the control group, as they improved adherence significantly by 23% (95% CI −33.97% to −11.72%; *P*<.001). The finding here suggests that simply reminding people to take their antibiotic medication can improve medication adherence significantly (Table 1).

Regarding the code entries, 63% (n=4489) were correct and on time across all conditions, while 21% (n=1497), although correct, were entered at the wrong time. This seems like a fairly reasonable result, as it was expected that some patients might take their pill at the wrong time. Only 7% (n=499) of the code entries consisted of wrong codes, which translated to a few patients taking the wrong pill. This result can be justified as patients who are on complex medication regimens (such as, for tuberculosis) do sometimes take the wrong pill.

The experiment included a consequence for nonadherence in the form of the screen relapsing to being blurry. To recall, once the participants’ screen was cleared, if they failed to enter the code, there was a 2% chance of “relapse” or the screen becoming blurry by 25%. The probability of “relapse” doubled each time the code was not entered. There were 73 participants in total who experienced relapse (each of these participants only experienced relapse once).

Our expectation was that once a participant had experienced relapse, they would be more adherent, but it seems that except for the incentive condition, adherence rates dropped after relapse. However, there may be an explanation for this result. Table 2 shows the round when relapse occurred for different participants. It can be seen that for more than half of the participants, relapse occurred when they only had 1, 2, or 3 code entries left. Since they knew that the game would end soon, they might have decided to forego entering the code and instead focus on the 2048 game. Since most participants experienced relapse very close to the end of the experiment, drawing meaningful insight into the relationship between relapse and adherence rate might not be appropriate.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram.

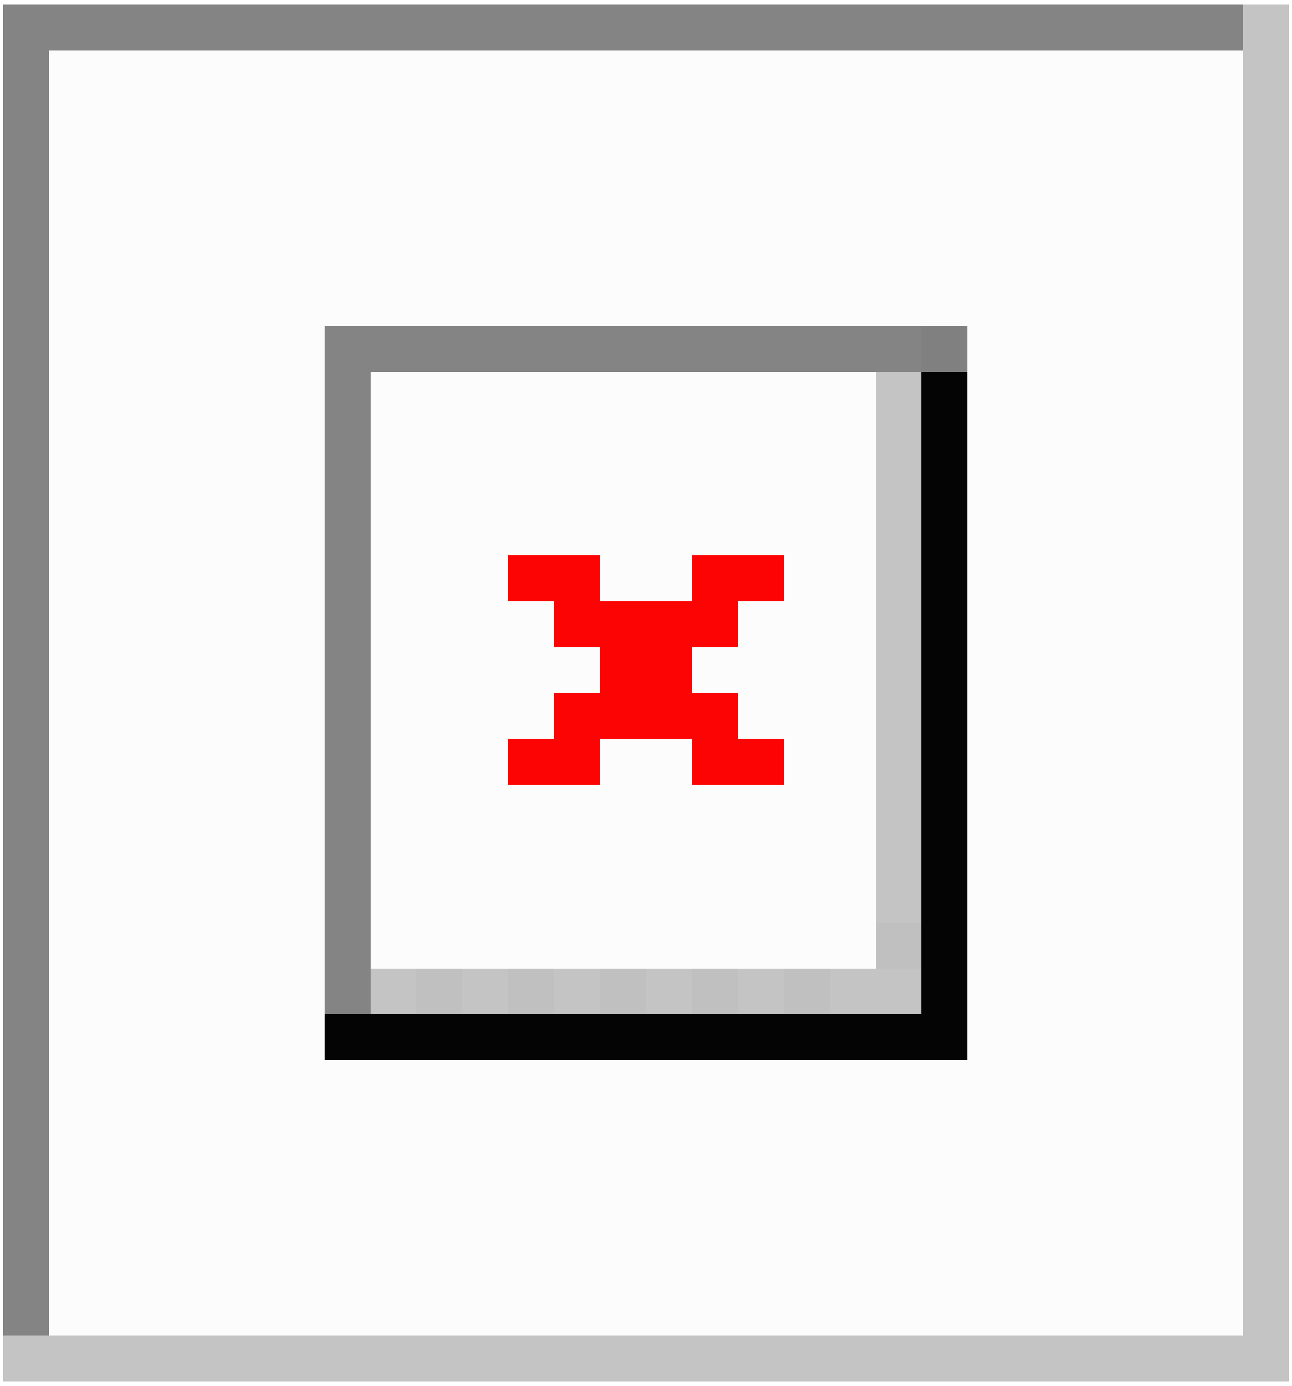

Table . Adherence rate of the control group and the intervention groups.

Group	Sample size, n (%)	Adherence rate (%)
Control group	104 (20)	44
Incentive group	106 (21)	52
Reminder group	97 (19)	67
Commitment device group	102 (20)	45
Elongated duration for symptoms group	100 (20)	54

Table . Adherence rates across the 5 conditions in the experiment.

Round when relapsed	Adherence rates (%)
7	4.1
8	5.5
9	4.1
10	19.2
11	8.2
12	16.4
13	21.9
14	20.5

Discussion

Overview

We intended to carry out a behavioral diagnosis of the medication adherence problem through a theoretically informed framework and then develop a model to simulate the nonadherence behavior. This constitutes the second stage of the theory-modeling-RCT cycle for developing behavior change interventions. The results of the modeling experiment showed that having theoretically informed interventions increased the likelihood for them to be successful. Furthermore, modeling can also help in identifying which interventions are most likely to work in the RCT.

It is worth discussing how good the 2048 experiment has been in modeling the nonadherence behavior. The modeling experiment seemed to have generated the same patterns that are expressed by patients such as forgetting to take the pill or adhering less to the regimen once the symptoms disappear. The results of the modeling experiment reflect this behavior of patients quite closely among the participants as well. The adherence rate found among the control group of the game experiment was 44%, which is quite similar to the adherence rate found among patients. While this statistic alone does not fully confirm the effectiveness of the gamification model, it is important to note that if the control group's adherence rate had been either very low or very high, it would have indicated that the 2048 experiment was not accurately modeling nonadherence behavior. Among the treatment conditions that were tested, it seems that reminders are only effective in increasing adherence rates.

Comparison to Prior Work

The results of the modeling experiment showed that providing incentives did not improve the adherence rate. Providing incentives was chosen as one of the treatment conditions because there is a lack of reinforcement for patients to continue adhering to their antibiotic medication once the symptoms disappeared [28]. However, Klein [29] maintains that rewarding behavior with money may have the undesirable effect of devaluing the intrinsic benefits of adherence, creating an even higher barrier to long-term adherence. Ideally, incentives should provide frequent, small (but tangible) rewards [30-32].

The results of the modeling experiment showed that providing reminders improves the adherence rate. There is evidence that the use of reminders improves the medication adherence rates for patients [33,34] because forgetting is the most prominent reason for nonadherence [28]. Using SMS text messaging for medication reminders appears to have a significant positive effect on medication adherence in other clinical areas such as, for example, mental health [35,36], with enduring effects [34]. The effectiveness of interventions using electronic reminders to improve adherence to antibiotics has not been tested in the field for real, so our experiment provides a promising indication that such an intervention is very likely to be effective.

While the use of reminders increased the adherence rate in the modeling experiments, we wanted to turn the tables and model an intervention that was yet to be carried out in a real-world setting. This motivated our selection of the use of commitment devices as one of the treatment groups in the modeling experiment. Commitment devices have been used in various contexts, such as smoking cessation, weight loss, exercise, and savings. Some studies have also explored the use of commitment devices for medication adherence among patients with chronic conditions, such as HIV, diabetes, or hypertension [28]. The results have been mixed, but some evidence suggests that commitment devices can improve medication adherence and health outcomes, especially when combined with other strategies, such as reminders, education, and incentives. Therefore, we aimed to test this strategy in our setting. We used the same protocol that was followed by the Department of Health and Boots UK in their RCT, and the results showed that the commitment sticker did not improve the adherence rates of the participants in the modeling experiment. Interestingly, a few months later, when the results of the RCT came out, it was found that the commitment sticker did not bring about any improvement in the adherence rates among patients as well. From the results obtained in the modeling experiment and their comparison with real-world analogs, it seems that the modeling experiment was able to simulate the nonadherence behavior of the patients.

The last treatment group of "elongated duration for symptoms" really shows the power of modeling experiments where we test a what-if scenario, which is extremely difficult to test in an RCT setting. The results from the experiment provide a proof of concept that if symptoms last longer people adhere more to their medication regimen. An interesting idea that comes to mind is that maybe the pills can be made in such a way that they keep the patients feeling sick until the last day of their treatment. Interestingly, a behavioral consultancy in India is testing a similar intervention. They are working on the issue of nonadherence to tuberculosis medication (which is an antibiotic medication but for a 6-month period) and have come across the same issue that patients stop taking their pills once the symptoms disappear. Rather than making people keep feeling sick (which is an extreme interpretation of the modeling experiment finding), they introduced an intervention to make patients realize that they are still sick even though the symptoms are gone.

In this study, we did not aim to identify which intervention or combination of interventions can be most effective in increasing medication adherence but rather to develop a model that can provide a platform to test various interventions and select the most effective ones to be included in an RCT. It is quite possible that an intervention is successful in an RCT but not acceptable by the target group. We would suggest that once we know from the modeling experiment which interventions show promise, we should carry out a reality check with the target group and understand how accepting they would be if that intervention was rolled out. In a recent study, researchers conducted an RCT to assess the value of SMS text message reminders as a means to improve medication adherence in patients receiving treatment for the prevention of cardiovascular disease [37]. They found that reminders improved adherence rate by 16%, but the interesting point to note is that for this study they contacted 7004 patients and only 303 agreed to receive text reminders. Although the study showed that reminders significantly improved adherence rates of the patients, the participant numbers also hint that many patients might not be interested in this service if it were to be rolled out. Hence, it is important to think about the acceptability of an intervention at the time of selecting interventions that are carried forward from the modeling stage to the RCT stage.

Limitations

The participants were screened on the basis of whether they were able to browse on the internet, as the laboratory experiments involved playing a computer game, which could be considered as a limitation. A significant proportion of the Pakistani population does not know how to use a computer, which restricted us to recruiting a representative sample of the computer-literate Pakistani population rather than a representative sample of the whole Pakistani population. Additionally, one argument that can be made against this modeling experiment is that participants might have adopted a strategy, whereby they enter the code to clear the screen, and once the screen is cleared, they cease to enter the code and maximize the time being spent to play the game, thereby maximize their earning in the experiment. However, this cannot be imagined to be a dominant strategy in the real-world setting, as patients do pay heed to the advice given by their doctors and have a high degree of trust and confidence in their doctors.

Conclusions

For this study, we set up the first behavioral science laboratory in Pakistan. We were keen on having the general public as our participants, and we knew that none of them would ever have participated in an experiment before, making them more receptive to the task. Using a game in the experiment proved to be a very important factor in attracting participants and greatly improved their engagement. As we said earlier, many participants requested to play the game again because they enjoyed it. We believe that more attention should be paid by researchers on how to keep the participants engaged when designing an experiment.

Our investigation answered our research question: whether gamified behavioral modeling is a useful tool to explain real health behaviors and help in identifying which interventions are most likely to work in a randomized trial. We examined a range of interventions that have been tested in real-world settings, and we discovered that our gamified behavioral simulation can model these varied patterns of results. We confirmed our hypothesis that the gamified behavioral simulation can replicate such results, which implies it would be a useful tool for predicting the success of interventions in the field.

Developing behavior change interventions is a complex process and thus requires a systematic way to approach the problem. The process should start from developing a theoretical understanding of the behavior at hand, followed by modeling the behavior to identify the exact mechanisms that might bring about the desired behavior change. Once the most suitable interventions are identified in the modeling stage, then an RCT should be carried out to test the intervention in a real-world setting. In this study, we have showed how this process can be followed in relation to the problem of nonadherence to antibiotic medication. Care must always be taken in extrapolating results from the laboratory to the real world, and caution is particularly called for when the laboratory model abstracts away from some important features such as the feelings of the patients or the environment in which patients are making their decisions. However, generating a hypothesis through simple modeling experiments can help us in developing the most effective interventions that can then be tested in the real-world setting (through RCTs).

Abstract

Background: Children who are going to undergo radiotherapy have displayed fear and anxiety. Therefore, a web-based serious game was developed as a psychological preparation to investigate if it could affect anxiety levels. In an earlier stage, children with experience of radiotherapy had been part of the developmental process.

Objective: The study aimed to investigate the feasibility in terms of reach, usability, and acceptability of a serious game about proton radiotherapy and to pilot that it did not increase anxiety levels in children aged 5 to 14 years undergoing radiotherapy.

Methods: The design was a randomized controlled pilot trial with predefined feasibility criteria. In total, 28 children were assessed for eligibility, and 23 met the inclusion criteria. They were consecutively randomized into 1 of 2 study arms. One child was excluded after randomization. If randomized into arm 1, the children received the intervention before treatment started. Children in arm 2 were treated as controls. Questionnaires with fixed answers were used to assess anxiety levels (an adapted version of the State-Trait Anxiety Inventory for Children) and experiences of gameplay (an adapted version of Player Experience of Need Satisfaction [PENS]). The children were asked to answer questionnaires at 5 different measurement occasions during their radiotherapy treatment.

Results: In arm 1, age ranged from 5 to 13 (mean 8.4, SD 2.4) years. In arm 2, age ranged from 5 to 11 (mean 7.6, SD 2.3) years. The sample consisted of 15 girls and 7 boys. The feasibility criterion that the children should play the game for 20 minutes or more was not met. Mean playtime for children in arm 1 was 32.1 (SD 23.8) minutes, where 18 children had played for at least 15 minutes. The criterion that 70% (n=16) or more of the participants should return all of the questionnaires was not met; however, more than 73% (n=16) returned the PENS questionnaires. The State-Trait Anxiety Inventory for Children was returned by 73% (n=16) on day 0, 77% (n=17) on day 1, 82% (n=18) on day 3, 82% (n=18) on day 6, and 86% (n=19) on day 15.

Conclusions: All feasibility criteria set for the study were not met, suggesting that adaptions need to be made if a future study is to be undertaken. Further, the analysis revealed that there was no indication that playing increased the children's self-reported anxiety. The PENS questionnaire adapted for children showed promising results regarding player satisfaction when using the serious game. When studying children with severe conditions and young age, 5 measurement occasions seemed to be too many. Measuring both player satisfaction or experience and knowledge transfer would be preferable in future studies.

Introduction

Background

Children with cancer are subjected to medical procedures that are both tiresome and painful [1]. Some children need to undergo radiotherapy. The treatment does not hurt but can be perceived as frightening [2]. Radiotherapy is usually given over a longer period of up to 6 weeks [3]. When radiotherapy is performed, the children are left alone in the enormous treatment room [4]. Since the children need to be completely still during the procedure, they are also fixated to stay immobilized [4,5]. When radiotherapy is targeted at the head, a mask is made and firmly fixated to the table [6]. The experience has been described as stressful and invoking anxiety and fear in both the children undergoing radiotherapy and their parents [7,8]. Several of the children are sedated, especially preschool children [2] because of the anxiety the procedure induces in the children [9]. Informing and preparing children who are going to undergo radiotherapy in order to decrease sedation or anesthesia (hereafter mentioned as sedation) or anxiety levels have been studied, and the effects have been minor [10,11]. However, with extensive psychological preparation, a decrease in the number of sedations was reported by Clerici et al [12]. An increased proportion of proton beam therapy is given as the preferred irradiation type, as it lessens short- and long-term toxicities and improves the quality of life outcomes for the children [13]. To receive proton therapy, the family often needs to go to a clinic far away from their home since only a few clinics provide such treatment [14,15]. In Sweden, where the study was executed, there is one national clinic providing proton beam therapy. Leaving their familiar surroundings can lead to further stress [16] on top of the pain and distress already caused by other cancer-related procedures the child has to endure [17]. It can therefore be argued that it is necessary to prepare the children by informing them about what radiotherapy is, what they can expect from the treatment that they are going to receive, and introducing them to the environment of the clinic so that they can feel that they are as much in control of the situation as possible [18].

In school, educational games have been proven to affect children's learning [19]. Games can be enjoyable, create engagement, and induce behavior changes [20]. Using digital tools and games to prepare children before procedures and having them take part in the development process are becoming more common [21-23]. Children with cancer have suggested that information should be given to elevate understanding about a specific treatment, which also encourages their ability to cope with the procedure [24]. Knowledge about the procedure increased, and the level of anxiety decreased with a digital tool when tested on children who were to undergo planned hospital procedures [25]. Several games have been developed with the intent to increase knowledge about the disease and treatment for children with cancer [26]. To decrease anxiety, a serious game about proton radiotherapy was developed together with children to function as interactive information before the procedure [23]. However, how well the game functions needs to be evaluated. Therefore, as psychological preparation before radiotherapy, a serious game as a supplement to preparation already in place at a proton clinic was evaluated for acceptability and impact.

Aim

The aim of the study is to investigate the feasibility in terms of reach, usability, and acceptability of a serious game about radiotherapy and to pilot that it does not increase self-reported anxiety in children aged 5 to 14 years undergoing radiotherapy.

Methods

Study Design

The study was designed as a feasibility and randomized controlled pilot study. The study provided an intervention using a prospective, waiting list control design.

Serious Game

For the intervention, children who would be undergoing radiotherapy played a web-based serious game on their tablet or computer to familiarize themselves with the radiotherapy treatment. The parents received a link to the game via email so that the children could access the game whenever they wanted. They used their own devices to play the game; however, they could also use the computers at the hotel they stayed at in conjunction with the treatment. No game controller was used, instead, the game was played with the computer's mouse or by touching the tablet's touchscreen. The game was designed as a doll house experience [27] where the children played an avatar that was in a proton radiotherapy clinic. In the game, a map was used that the child could click on to access different rooms in the clinic to explore them independently. The rooms contained information about the procedure of radiotherapy for educational purposes as displayed in Figures 1 and 2. It also contained mini-games and game elements that were placed there to make exploration of the play setting interesting [23]. The game had been developed through an iterative process together with 9 children with experiences of radiotherapy treatment, which influenced the game's design and led to numerous changes in it [23]. The changes pertained to the design of how the treatment was displayed and explained within the game and the language [23]. To be able to explore the clinic's facilities and get informed about the procedure of radiotherapy is a form of psychological preparation [28]. The purpose of psychological preparation is to mitigate the fear of the unknown [29] and is intended to reduce anxiety before procedures [30].

Figure 1. Screenshot from the game the participants were subjected to within the randomized controlled trial showing the first encounter of where radiotherapy is performed and where the avatar will later undergo radiotherapy.

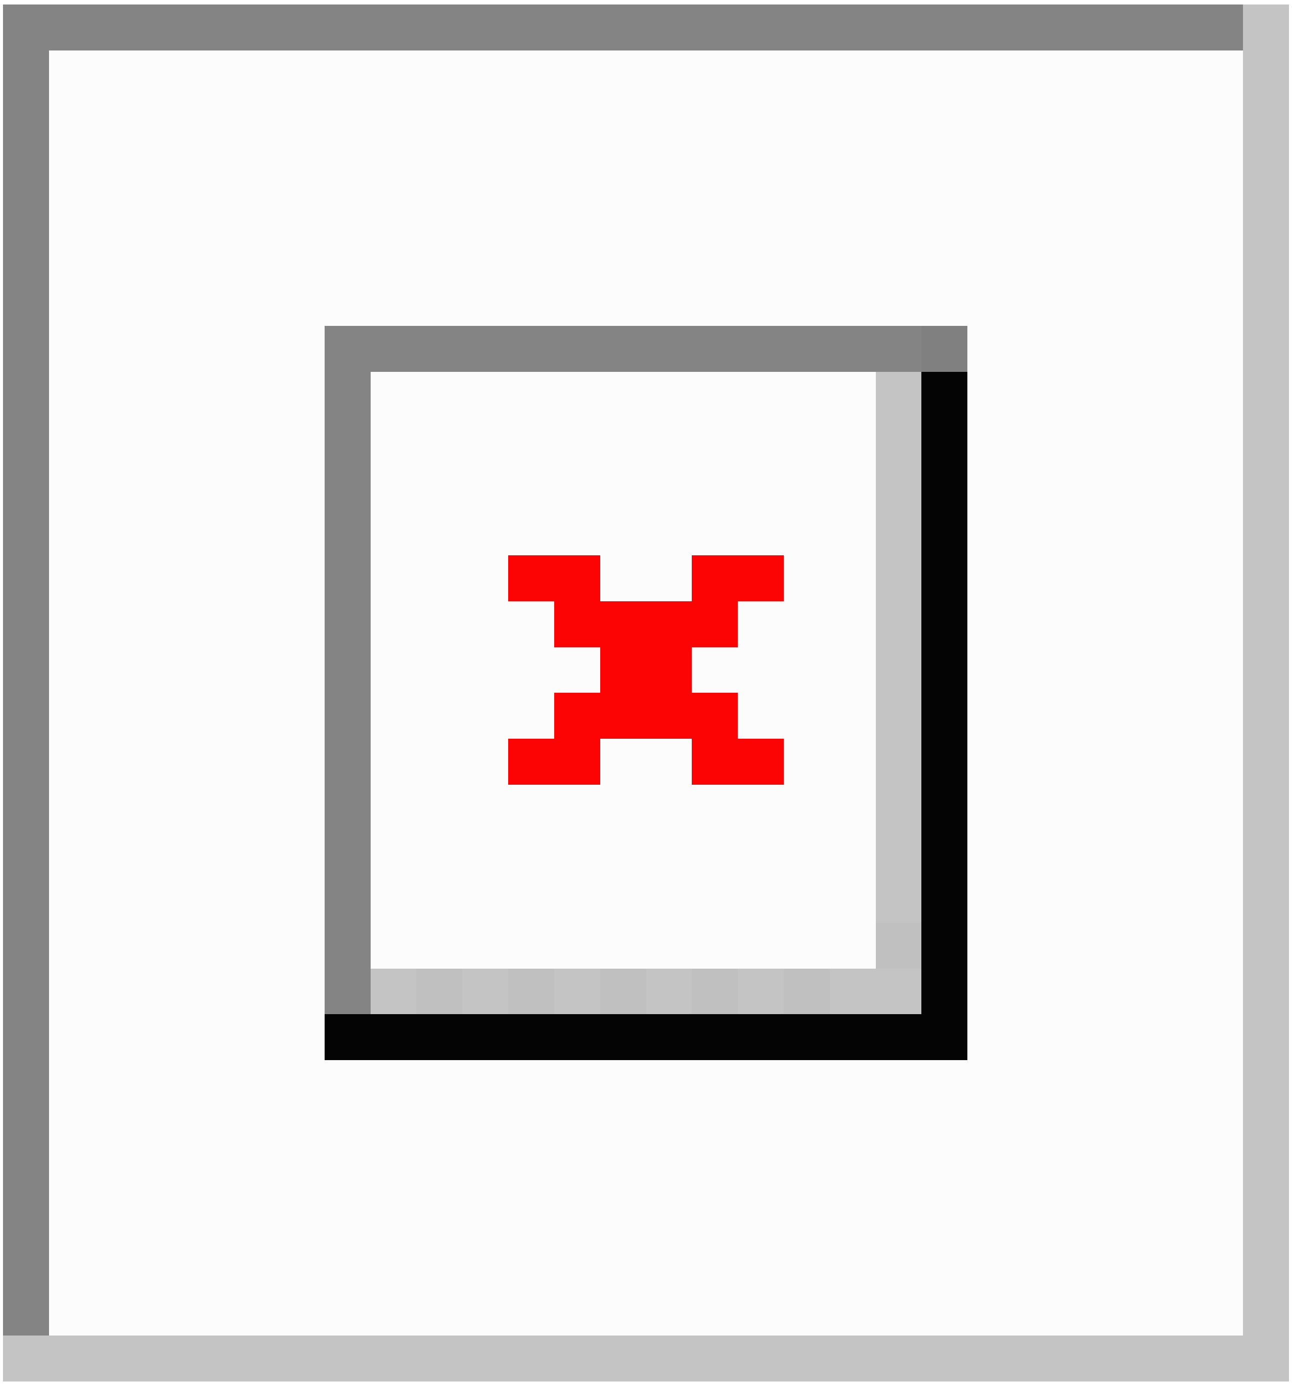

Figure 2. Screenshot from the game the participants were subjected to within the randomized controlled trial showing the monitor room where the staff provide therapy and observe the avatar undergoing radiotherapy.

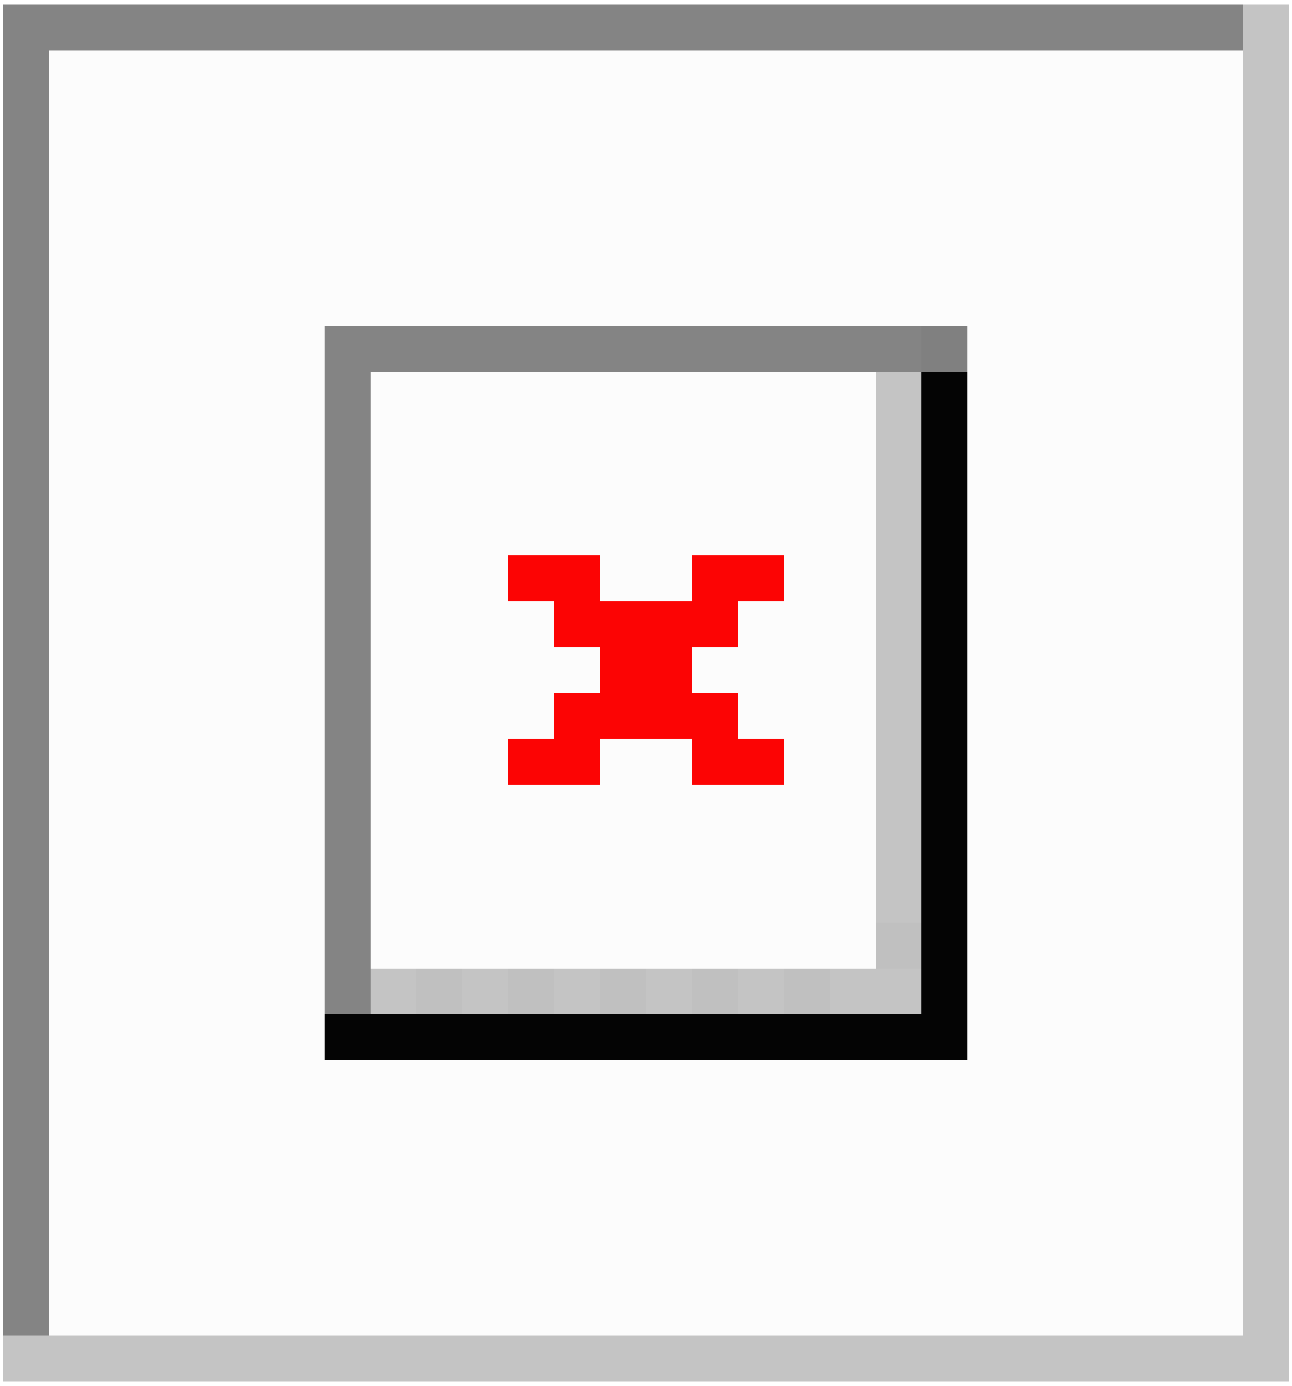

Recruitment

Recruitment started in February 2021 and completed in August 2022. During that period, 26 children were considered eligible for inclusion. When children between the ages of 5 and 15 years, living in Sweden, had been scheduled to have radiotherapy at the clinic, a written invitation about the study was sent to them by post. A few days later, a pediatric or oncology nurse or a coordinator contacted the family by telephone with information about the study and asked for permission for the researcher to contact them. Upon agreement, the researchers contacted them and gave further information orally, and if oral consent was granted, they were then emailed all further information about the study. Exclusion criteria were children living in countries other than Sweden, inability to understand Swedish, and severe mental disability. Two children were excluded due to language barriers during recruitment.

The children were divided into 3 age groups: ages 5-7, 8-10, and 11-14 years. They were then randomly assigned into 1 of 2 study arms using stratified randomization in blocks to achieve balanced groups. The parents received information about which arm their child had been randomized to. Study arm 1 received the intervention 1 or more days before starting their therapy. Children assigned to arm 2 received the game 3 days after they started their therapy since it was not considered ethical to invite the children to a game study and then not let them play the game [31].

Ethical Considerations

Ethics approval was received by the Swedish Ethical Review Authority (2020‐05578) before the study was started. The study was registered at ClinicalTrials.gov (NCT04728555). Upon agreement to participate in the study, the children received a 6-digit participation ID, which was used to sign into the game to be able to track time played, and the number was also used as identification for the questionnaires; hence, the data became anonymous. There was one separate list where participants' names and contact information were kept together with their participation ID. The children's legal guardian signed a written consent form on their child's behalf and their own behalf. Children also gave their assent to participate. Neither the children nor their guardians received any compensation for participating in the study.

Feasibility Criteria and Measurements

The feasibility criterion for success was that 80% (n=18) of the participants had played the game for 20 minutes or more. Further, 70% (n=17) or more of the participants should have returned all questionnaires partially or fully answered State-Trait Anxiety Inventory for Children-State Anxiety (STAIC(S)) and Player Experience of Need Satisfaction (PENS). The premises of the threshold were set to find out which days most children filled out the STAIC(S) to establish for future studies how many measurement occasions are plausible. A hypothesis was tested, which was that children in arm 1 should not communicate more anxiety than children allocated to arm 2. In addition, reach was measured by assessing whether prospective participants received information about the study.

There were 4 different questionnaires distributed to participating children: the STAIC(S) and State-Trait Anxiety Inventory for Children-Trait Anxiety [32], the PENS [33], and a customized questionnaire about radiotherapy developed by the research team (which will be reported elsewhere). Parents answered an adult version of the State-Trait Anxiety Inventory (STAI), which included 10 questions on a 4-point Likert scale [34]. They also answered a questionnaire providing background variables. Children who were not able to read were helped by their parents to answer the questionnaires and interpret the scale alternatives.

An adapted version of the short STAIC with a 3-point Likert scale was used to measure the children's anxiety [32]. The short form of STAIC consists of 6 questions; however, 2 questions were added from the long version of STAIC to provide further insight into anxiety, making a range from 8 to 24 points. Hereafter, the adapted version used in the intervention will be referred to as STAIC(S). According to the guidelines of interpretation, a calculation based on 8 questions indicated 12 points as the cutoff for anxiety. To not overestimate the children's anxiety, the cutoff was set at 13 points for feeling anxious. The State-Trait Anxiety Inventory for Children-Trait Anxiety is a questionnaire consisting of 10 questions on a 3-point Likert scale [32].

The PENS questionnaire consists of 16 questions on a 7-point Likert scale [33]. Approval was given for the questionnaire to be translated into Swedish and adapted for children by the owner company, Immersyve. It was first translated from English into Swedish by a group consisting of 2 pediatric nurses, 1 researcher in informatics and media, and 1 pediatric psychologist and then backward by an interpreter with English as their mother tongue. Two questions were related to multiplayer games, which were not relevant to the study since the game is a single-player game, so they were excluded. The questionnaire was tested for face validity on 4 healthy children between the ages of 5 and 11 years through interviews. The questionnaire was made in 2 versions, 1 for younger children (5‐7 years) and 1 for older children (8‐14 years). The younger population had difficulty understanding the 7-point Likert scale. Therefore, it was changed to a 3-point Likert scale. Furthermore, the language was adapted to the young population and consisted of 8 questions (range 8‐24). For the older children (8‐14 years), the questionnaire consisted of 14 questions (range 14‐98). The cutoff level for satisfaction with the game experiences was set at 16 for PENS (5‐7 years) and at 65 for PENS (8‐14 years), reaching two-thirds of the total score (66%) for both scales. The fourth questionnaire (customized questionnaire about radiotherapy) included 6 questions about radiotherapy on a 4-point Likert scale.

Data Collection

At 1‐3 days prior to the start of treatment, the children randomized into arm 1 (intervention) received a web link to the game, and children randomized into arm 2 (control) received the web link after their third day of treatment. The children and parents received instructions stating that they were free to play the game as much or little as they liked. Each participant was given a unique participation number sent to their guardian's email, which was used to access the game. A software engine was used to store the playtime for each number, and the data were deleted after a month. A member of the team who only had the participation number collected the data from the engine. The playtime was measured cumulatively, and no record was kept on how many times each participant had chosen to access the game. For 2 players, the information was lost. Therefore, the parents were emailed to make an estimation of their children's playtime. Children in both arms answered the same questionnaires 1 day before treatment started (day 0), the first day of treatment, the third day of treatment, the sixth day of treatment, and the last questionnaire approximately 15 (±4) days into treatment. The children received a diary notes form on their first day at the clinic where they were asked open questions about how they perceived the game, which will be reported elsewhere. The questionnaires were administered to the children and parents by the receptionist staff at the clinic before they were due to have the treatment. The answered questionnaires were left in a mailbox at the clinic. The children and parents were asked to arrive before their appointment on the days of the study so that they would have time to answer the questionnaires before that day's treatment. The total time children spent playing the game was collected digitally for each participant. STAIC(S) was collected on all 5 measuring occasions, PENS at 1 time, and radiotherapy questionnaire on 4 occasions. Parents answered demographic questions and STAI at the first measuring point. During participation in the study, the children and their parents received information according to standard care.

Data Analysis

Descriptive statistics were used to gain insights into the collected quantitative data. To analyze differences between the arms, Fisher exact test, Mann-Whitney *U* test, Pearson chi-square, and Wilcoxon matched-pair signed rank were used. Spearman rank order correlation was used to analyze statistically significant associations between variables within the sample. In addition, Cronbach α was used to calculate the internal consistency between concepts. SPSS (version 28.0; IBM Corp) was used for the analyses, and the findings were considered to be statistically significant if a *P* value <.05 was reached. The CONSORT (Consolidated Standards of Reporting Trials) guideline was followed for statistical analysis and to report the study [35].

Results

Feasibility in Terms of Reach and Background Variables

The study aimed to reach all patients within the age group who were to have radiotherapy. After the study had been finished, the nurses at the radiotherapy clinic went through the records of all children who had passed the clinic within the study's timeframe. There had been 28 children who had been assessed for inclusion, of which, 26 of the children were eligible to take part in the study (Figure 3). A total of 3 children declined participation, and 1 child was lost to participation due to administrative issues, resulting in 22 (85%) children's completion of at least one questionnaire of the study. There were no differences between the intervention arm and controls regarding sex, age, diagnosis, sedation, and parents' educational level.

In total, 11 children were randomized into the intervention arm, and another 11 into the control arm. In arm 1, age ranged from 5 to 13 (mean 8.4, SD 2.4) years. In arm 2, age ranged from 5 to 11 (mean 7.6, SD 2.3) years. For the variances of ages, see Table 1. The sample consisted of 15 girls. A majority of the children (n=16) were diagnosed with brain tumors and 6 with extracranial solid tumors. The number of fractions received varied from 14 to 33 with a mean of 27 (SD 5.7) fractions. In total, 11 children received sedation, and 6 of these children received the intervention. All 5- and 6-year-old children were sedated, and 3 of 4 children among the 7-year-olds were also sedated. The sedated children's answers are included in the analysis. Most of the children (n=21) lived with 2 parents, while 1 child lived with a single parent. A total of 16 children lived with a parent who had attended higher education and 4 lived with a parent who had finished high school, and there were 2 children for whom no data were attained.

Figure 3. CONSORT (Consolidated Standards of Reporting Trials) flowchart depicting enrollment and the days the questionnaires were administered and how many participants returned them for each arm. PENS: Player Experience of Need Satisfaction; RT.Q.: customized questionnaire about radiotherapy; STAI: State-Trait Anxiety Inventory; STAIC(S): State-Trait Anxiety Inventory for Children-State Anxiety; STAIC-T: State-Trait Anxiety Inventory for Children-Trait Anxiety.

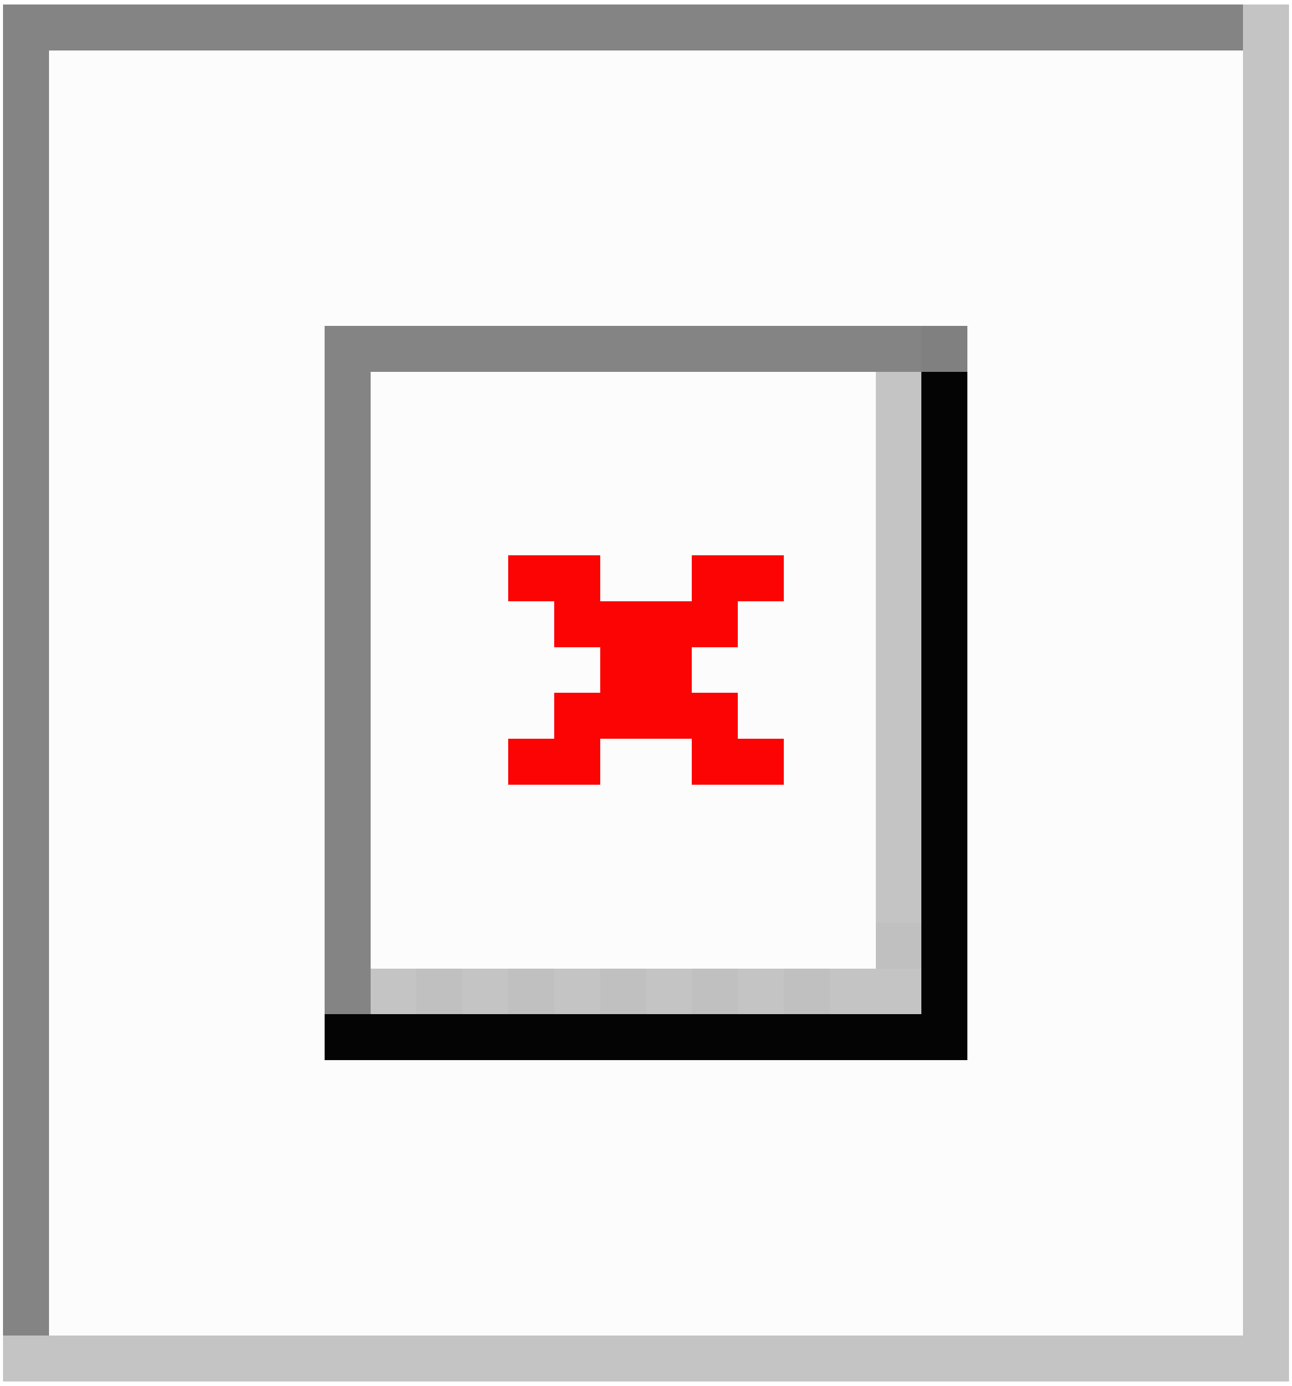

Table . Children's (n=22) background variables divided by allocated arm. Displaying number of children's sex, age groups, sedated or awake status during radiotherapy, diagnosis, and parental education level with the total amount of each arm for each variable and total when merging the 2 arms.

Feasibility in Terms of Usability and Acceptability of the Intervention

The predefined feasibility criterion was that 80% (n=18) of the children should play for at least 20 minutes to determine whether they found the game acceptable. There were 6 (27%) participants who played the game for less than 20 minutes, and 18 (82%) of the participants played for more than 15 minutes; hence, the criterion was not fulfilled. However, the mean time playing was 31 minutes for the entire sample (median of 27 minutes) spanning from not playing the game at all to playing for 85 minutes (Table 2). The intervention arm had a mean time playing the game of 32.1 (SD 23.8) minutes, while the mean time was 29.9 (SD 19.0) minutes for the control arm. There were no differences in playtime between the two.

To measure the participants' self-rated anxiety, the STAIC(S) was administered at 5 measurement points. The estimation was that 70% (n=17) of the participants should return the forms partially or fully completed. In total, 9 (41%) children returned all 5 forms of STAIC(S), and 13 (59%) children failed to return 1 or more forms. To measure the usability of the game, their experiences of the game were measured through the 2 versions of the PENS questionnaire, which 16 (73%) participants returned. A total of 8 participants answered the 5 - 7 years version, and 8 participants answered the PENS questionnaire (8 - 14 years).

Table . Description of children's playtime of the serious game, Player Experience of Need Satisfaction (PENS) score, and if the child was sedated or awake during radiotherapy (n=22).

Participant	Age (years)	Time played (minutes)	PENS score	Sedated
Intervention[a]				
E1	5	29	11[b]	Sedated
E2	7	18	19[b]	Sedated
E3	7	20	18[b]	Awake
E4	7	58	19[b]	Sedated
E5	7	85	18[b]	Sedated
E6	8	10	—[c]	Sedated
E7	8	23	45[d]	Awake
E8	8	27	70[d]	Sedated
E9	10	45	—	Awake
E10	12	0	—	Awake
E11	13	38	67[d]	Awake
Control [e]				
L1	5	0	—	Sedated
L2	5	10	—	Sedated
L3	5	20	16	Sedated
L4	5	60	22	Sedated
L5	6	23	20	Sedated
L6	9	17	34	Awake
L7	9	35	66	Awake
L8	9	38	—	Awake
L9	9	60	88	Awake
L10	10	39	47	Awake
L11	11	27	26	Awake

[a]Age: mean 8.4 (SD 2.4) years and time played: mean 32.1 (SD 23.8) minutes.

[b]PENS (children 5 - 7 years) score range 8 - 24, mean 17.9 (SD 3.3) based on both arms (n=8).

[c]Missing value.

[d]PENS (children 8 - 14 years) score range 14 - 98, mean 55.4 (SD 20.8) based on both arms (n=8).

[e]Age: mean 7.6 (SD 2.3) years and time played: mean 29.9 (SD 19.0) minutes.

Anxiety

To measure whether children who received the intervention communicated an increase in anxiety compared to the controls on their first day of radiotherapy, the Mann-Whitney *U* test was used. No perceived differences between the arms could be found (*P*=.81). There were no differences measured in anxiety between the arms across all 5 assessment occasions.

The number of children who indicated anxiety (13 - 24 points) through the STAIC(S) is presented in Table 3, where the children receiving the intervention and the control arm are displayed separately. There were 6 children sedated in the intervention arm and 5 in the control. The following response rates at each measurement occasion were collected: 73% (n=16) on day 0, 77% (n=17) on day 1, 82% (n=18) on days 3 and 6, and 86% (n=19) on day 15 (Table 3). Over time, the children's anxiety decreased, but no significant difference could be found between the arms. There was no significant correlation found between STAIT (trait anxiety) and STAIC(S) (state anxiety) in the current sample (*P*=.34). The items' internal consistency of STAIC(S) was calculated by Cronbach α based on 89 questionnaires that had been obtained during the study, and the α value was 0.85.

On day 0, the parental STAI questionnaire was administered to 43 parents, and 33 answers were obtained. The hypothesis was that if the parents presented higher levels of anxiety, so would their children. Since there were considerably more mothers who returned the parental STAI, the hypothesis was only tested between mothers and their children. No correlation could be found between the mother's reported trait anxiety levels and the children's before treatment started. No correlation could be found between the mother's state anxiety levels and those of their children.

Table . The number of children reporting anxiety (13 - 24 points) through the State-Trait Anxiety Inventory for Children-State Anxiety (STAIC(S)) questionnaire at 5 measurement occasions (n=22).

Measurement occasions	Intervention			Total, n	Control			Total, n
	Awake, n (%)	Sedated, n (%)	Total, n		Awake, n (%)	Sedated, n (%)	Total, n	
Day 0 (n=16)	2 (29)	4 (57)	6	7	3 (33)	2 (22)	5	9
Day 1 (n=17)	1 (11)	4 (44)	5	9	4 (50)	2 (25)	6	8
Day 3 (n=18)	1 (11)	3 (33)	4	9	2 (22)	1 (11)	3	9
Day 6 (n=18)	2 (22)	3 (33)	5	9	1 (11)	1 (11)	2	9
Day 15 (n=19)	2 (20)	2 (20)	4	10	1 (11)	1 (11)	2	9

Serious Game About Radiotherapy

No correlation between time playing the game and anxiety levels measured on day 1 was found in the intervention arm nor was it found when combining the 2 arms on day 6. To check the translated and modified PENS questionnaire's items for internal consistency and accuracy, we used the concepts that were established in PENS (version 1.6). PENS (5 - 7 years) consisted of 8 questions: 2 items related to competence, 2 items to autonomy, and 4 items to presence, with a sample unit of 8. Six respondents were girls. The Cronbach α score for competence was 0.89, autonomy 0.57, and presence 0.28. Descriptive statistics of the concepts for PENS (5 - 7 years) are reported in Table 4. For PENS (5 - 7 years), the score could range between 8 and 24, and the mean score was 17.9 (SD 3.3; Table 2). No correlation between the time playing the game and the scoring of the questionnaire for the PENS (5 - 7 years) was established. In total, 7 (88%) of the participants had a score that was 16 or higher, indicating that they found the game experience satisfying (Table 2).

PENS (8 - 14 years) consisted of 14 questions, and there were 4 items related to competence, 3 to autonomy, and 7 to presence, with a sample unit of 8. Descriptive statistics of the concepts for PENS (8 - 14 years) are reported in Table 5. The Cronbach α score for competence was 0.85, autonomy was 0.87, and presence was 0.91. For PENS (8 - 14 years), the score could range between 14 and 98, and the mean score was 55.4 (SD 20.8; Table 2). A correlation between the time playing the game and the scoring of the questionnaire for the PENS (8 - 14 years) could not be found with a *P* value of .05. However, it is noteworthy that it resulted in a *P* value of .06. In total, 4 (50%) of the participants had a score that was 65 or higher, indicating that they found the game experience satisfying.

Table . The three concepts by subscales present in Player Experience of Need Satisfaction (5-7 years; calculated from replies by 8 participants).

Concepts	Scores from participants aged 5 - 7 years on a scale ranging from 1 to 3		
	Min	Max	Mean
Competence	2.38	2.63	2.50
Autonomy	1.63	2.50	2.06
Presence	1.88	2.50	2.13

Table . The three concepts by subscales in Player Experience of Need Satisfaction (8-14 years; calculated from replies by 8 participants).

Concepts	Scores from participants aged 8 - 14 years on a scale ranging from 1 to 7		
	Min	Max	Mean
Competence	3.89	6.11	5.22
Autonomy	3.78	4.78	4.11
Presence	2.63	4	3.20

Discussion

Principal Findings

Web-based games are easily accessible and can work as psychological preparation for children with cancer [26]. Preparing children who are going to undergo radiotherapy with the help of a serious game could be a means to make the experience somewhat less frightening. All 3 predefined feasibility criteria of the study were not met. Less than 80% of the children played the game for 20 minutes or more. More than 70% returned the PENS questionnaire. Less than 70% returned all the questionnaires of STAIC(S). Although, on the last 3 occasions of assessment, more than 80% of the questionnaires were returned. The results did not show that the serious game increased the children's anxiety, and over the trajectory of the study's time, there was a decrease in anxiety levels in the 2 arms. The study achieved its desired reach by recruiting through nurses who contacted children who were to visit the clinic. Randomization was also done according to the pilot study protocol.

Anxiety

Since the sample size was small, no difference could be found in anxiety levels between the ones receiving the intervention and the control arm, which was similar to findings in earlier studies [10,11]. The study relies on the participating children being able to identify their own feelings and express them accordingly to the scale in the STAIC(S). The scale, in its full version, is one of those most used in research and has been found to be both valid and reliable among children with cancer [36]. Children need to have had experiences of feelings to have learned their meaning if they are to be able to label them with words on a questionnaire. [37]. Nevertheless, it is preferable that children themselves report their symptoms [38]. The STAIC(S) is not validated for younger children (5 - 7 years), which means another instrument would be preferable; for example, the STAIC(S) redesigned and including pictures aimed at younger children could be an option [39].

The sample included children who were sedated. Children who are sedated are not at risk of not being still during radiotherapy [5]; nevertheless, they still can feel fear and anxiety concerning the procedure [40]. Therefore, to include their answers about how they perceived the game and rated their anxiety is valuable to report since few earlier studies have measured children's self-rated anxiety when undergoing radiotherapy.

Since 2 items were added to the short form of STAIC (including 8 instead of 6 questions), Cronbach α was used to assess the internal consistency by reliability tests, and the α value was 0.85, which is considered to prove high internal consistency between the items [41].

Playing Time and PENS Scores

The feasibility criteria of the study were not met since fewer children than predicted played the game for 20 minutes or more. The children were free to play the game as much or little as they liked, resulting in a few children not playing the game at all. However, the time spent playing the game was almost the same in the arms, indicating an interest in the game among the children participating in the study. Other studies have used various specified game dosages and a set time playing the intervention, which in some cases resulted in a correlation to statistically significant findings [42]. To not have a predetermined play time but instead monitor how much time children spend playing the game is a way to assess whether children find serious games acceptable [43]. Cronbach α was used to assess the internal consistency through reliability tests of the 2 adapted PENS questionnaires developed for the study of the concepts [41]. For PENS (8 - 14 years), the reliability was high. However, the number of participants that the calculation was established for was low. Therefore, the questionnaire should be validated by factor analysis, and reliability tested on a larger sample of children in a Swedish context [44]. Further, the validation of the English version was conducted using university students [33]. For PENS (5 - 7 years), the reliability was low for 2 of the concepts and high for 1. This could be an effect of the change from the 7-point Likert scale to a 3-point Likert scale and that it consists of fewer questions. Therefore, the PENS (5 - 7 years) also needs to be validated for children in a Swedish context.

Methodological Considerations

Following the intention-to-treat analysis, the 2 children who never opened or played the game are part of the analyzed material as they answered questions. For future studies, predetermined play time of the intervention could be a means to establish whether it has an effect on what the study measures [42] and exclude those not achieving predetermined play time in the analysis. Fewer children than predicted returned all of the STAIC(S) questionnaires. For future studies, fewer assessment point days including fewer questions would be preferred when researching the population. In addition, another option to evaluate the effect of the intervention could be to measure the number of sedations before and after the intervention. For the study to reach power, a power calculation was made showing that 60 children needed to be enrolled. A strength of the study was that the clinic involved has a nationwide uptake and therefore reached all children within the age groups. However, after 1.5 years, only 28 children had been assessed for eligibility. The study was run during the COVID-19 pandemic, which might have affected referrals to the clinic. Despite prospective inclusion, there were more girls than boys included, which could be due to chance on account of the small sample size. Future studies need to have an even sex distribution to ensure generalizability. A weakness in the study was that it was unable to reach the estimated goal for power; and therefore, the criterion of a difference in the anxiety levels between the arms could not be found. With a larger study sample size, the criterion might have been met. Therefore, collaboration with other proton clinics is warranted to obtain a larger sample. Hence, the evaluation of the feasibility of the study provided information on how to improve the study protocol for future studies.

Furthermore, it is not possible to know if the children chose to answer the questionnaires before the treatment or after. On the questionnaires, the child or parent wrote the date of treatment they were in; however, the date sometimes differed from the date in their treatment plan. Staff had on occasion missed handing out the questionnaires on the correct date. In the future, a more precise collection is warranted, for example, having the questionnaires on the web would be favorable [45], and reminders could increase response rates [46].

Implications for Future Studies

Some lessons learned through the feasibility study are the following: make sure that children in the study population under investigation have the possibility to take part as planned. Time needs to be set off for answering questionnaires within the hospital procedure schedule. When studying children with severe health conditions, it is important to be mindful of how many questions is possible for them to answer before they run out of energy. To test if games do what they are intended for within medicine and indicate if they would be used, it would be preferable to measure both player satisfaction and knowledge transfer.

Conclusions

All feasibility criteria set for the study were not met, suggesting that adaptions need to be made if a future study is going to be undertaken. It is preferable to do a feasibility study since it is a way to detect the advantages and disadvantages of the study protocol and to optimize future studies. There was no indication found that playing the serious game increased the children's self-reported anxiety toward undergoing radiotherapy. The PENS questionnaire showed promising results regarding player satisfaction in the use of the serious game within health care. When serious games are used as interventions, it is necessary to evaluate player satisfaction in future studies, and for that reason, the PENS questionnaire for children needs to be validated. To avoid dropout from the study, it would be commendable to not have as many as 5 measurement occasions for a group of the current age.

Acknowledgments

The authors would like to thank the children and parents who took the time to participate in the study and the personnel at the clinic for helping with the administration of the study. The study was funded by the Swedish Childhood Cancer Fund (grant KP2020-0010).

Abstract

Background: Surgery is an essential treatment for early-stage breast cancer. However, various side effects of breast cancer surgery, such as arm dysfunction and lymphedema, remain causes for concern. Rehabilitation exercises to prevent such side effects should be initiated within 24 hours after surgery. Virtual reality (VR) can assist the process of rehabilitation; however, the feasibility of applying VR for rehabilitation must be explored, in addition to experiences of this application.

Objective: This study explored patients' attitudes toward and experiences of using VR for their rehabilitation to determine the feasibility of such VR use and to identify potential barriers.

Methods: A phenomenological qualitative study was conducted from September to December 2021. A total of 18 patients with breast cancer who had undergone surgical treatment were interviewed using open-ended questions. The Colaizzi 7-step procedure for phenomenological analysis was used for data analysis. To ensure high study reliability, this study followed previously reported quality criteria for trustworthiness.

Results: Three themes were identified: (1) VR was powerful in facilitating rehabilitation, (2) early and repetitive upper limb movements were an advantage of VR rehabilitation, and (3) extensive VR use had challenges to be overcome. Most of the interviewed patients reported positive experiences of using VR for rehabilitation. Specifically, VR helped these patients identify appropriate motion and angle limits while exercising; in other words, knowledge gained through VR can play a key role in the rehabilitation process. In addition, the patients reported that the use of VR provided them company, similar to when a physiotherapist is present. Finally, the gamified nature of the VR system seemed to make VR-based rehabilitation more engaging than traditional rehabilitation, particularly with respect to early rehabilitation; however, the high cost of VR equipment made VR-based rehabilitation difficult to implement at home.

Conclusions: The interviewed patients with breast cancer had positive experiences in using VR for rehabilitation. The high cost of both VR equipment and software development presents a challenge for applying VR-based rehabilitation.

Introduction

Breast cancer is a major global health problem. In Taiwan, more than 10,000 women are diagnosed with breast cancer every year; approximately 80% of these diagnoses are early-stage breast cancer and most require surgical treatment [1]. More than 1 in 5 women who are breast cancer survivors might eventually develop upper limb lymphedema [2]. In addition, the life expectancy of patients with stage 0 to stage 3 breast cancer is 20 to 32 years [3]. Breast cancer treatments include surgery, radiation therapy, chemotherapy, endocrine therapy, and targeted therapy. Because of advancements in diagnosis and treatment in recent years, the 5-year relative survival rate of breast cancer is now higher than 80% [4]. However, both ancillary dissection and axillary radiation are known to increase the incidence of lymphedema and axillary web syndrome [5]; associated symptoms include pain, upper extremity weakness, paresthesia, and limited range of motion (ROM), each of which can not only delay the commencement of radiation therapy but also lead to patients being unable to perform basic self-care tasks. This is a problem because less-mobile patients are more likely to experience side effects after surgery; for example, a frozen shoulder is a side effect that commonly occurs in the short term as a result of immobility after surgery [6]. These associated symptoms may persist for up to 1.5 years after surgery and therefore predispose patients to depression and other mental health conditions that can become long-term health problems [7,8].

Studies have suggested that the early commencement of postoperative rehabilitation exercises, including upper extremity abduction and flexion exercises, can reduce the risk of upper extremity pain and dysfunction [9,10]. Although the optimal time to start ROM exercises remains unclear, one study suggested that activity recovery tends to be more successful following earlier rehabilitation [11]. Typically, rehabilitation is recommended to be commenced within the first 7 days after surgery, with shoulder ROM initially being limited to 90° [12]. Hence, a patient's willingness to undergo rehabilitation after surgery to prevent their arms from becoming motionless is essential. However, after surgery, a patient's motivation to undergo physical rehabilitation tends to be low because of wound pain and fear of movement [13,14].

Virtual reality (VR) can reduce fear of movement and improve motivation to engage in rehabilitation. In addition, VR can promote compliance and rehabilitation success among patients [15-17]. Furthermore, VR appears to be effective in increasing shoulder ROM compared with standard physiotherapy for postoperative rehabilitation in patients with breast cancer [18]. The use of VR for rehabilitation is not new; however, feasibility studies that use VR to provide individualized, progressive practice for arm movements after surgery for breast cancer remain scarce. Feasibility research is often conducted prior to a randomized controlled trial [19]. In recent years, most studies investigating VR for rehabilitation in patients with breast cancer have used a randomized controlled design and have been prospective, adequately powered, and methodologically rigorous. Nevertheless, according to According to the recommendations of the VR-CORE (Clinical Outcomes Research Experts) [20], the development of new VR content should include 3 phases: VR1 to VR3. VR1 provides guidance for the development of new VR content; VR2 constitutes early testing related to the feasibility, acceptability, tolerability, and initial clinical efficacy of VR; and VR3 evaluates the efficacy of VR in comparison with controls. Bypassing feasibility and accessibility tests to jump immediately to clinical trials may lead to a gap between program development and bedside application and cause barriers to implementing VR in practice. Even though there is sound evidence that VR is effective in improving rehabilitation effects in patients with breast cancer, VR is not currently used in many clinical settings. According to Brennan et al [21], barriers to the implementation of VR include usability problems, cognitive limitations, cost, a lack of patient safety, low patient motivation, and negative patient responses. In addition, VR's unfamiliarity to many patients may dampen their willingness to use VR [22]; thus, patients' attitudes, experiences, and opinions related to VR must be understood. Further explorations of feasibility and accessibility are recommended for the use of VR in health care [23,24].

To the best of our knowledge, most studies regarding postoperative rehabilitation in patients with breast cancer have been clinical trials (ie, VR3) that evaluated only treatment effects, such as pain, grip power, muscle power, or ROM; VR2 studies are skipped. This study used a phenomenological approach to investigate the feasibility and experiences of a VR rehabilitation program (ie, this was a VR2 study) in patients with breast cancer. Therefore, this study was conducted to answer the following questions: (1) What are the lived experiences of patients using VR for arm rehabilitation? (2) How do they perceive the process? In answering these questions, this study determined the clinical effectiveness of and barriers to VR rehabilitation as a prelude to a definitive randomized controlled trial.

Methods

Design and Development of the VR System

The VR system in this study was designed and developed in accordance with the VR–CORE–VR1 guidelines [20]. Our VR design team was a multidisciplinary team comprising users and technicians. The rehabilitation program was developed in 3 stages. The first stage was based on inspiration gained through empathy. Specifically, interviews were held with 2 patients who were invited to share their rehabilitation experiences and express their perspectives and opinions to facilitate the design of an effective VR-based treatment program. The interview questions in this stage considered (1) smart device use behavior and (2) willingness and acceptability to use VR rehabilitation systems. The second stage involved ideation through team collaboration. Specifically, our team comprised experts in surgery, rehabilitative physicians, and software engineering, as well as a case manager. Innovative ideas were generated through methods such as brainstorming and collective ideation, and the ideas that were most suitable for prototyping were then compiled. The third stage involved prototyping based on user feedback. Specifically, further discussions were held with the aforementioned 2 patients to obtain further information. Our team then built prototypes to test 3 VR rehabilitation exercises prior to implementation (Table 1). Ultimately, we extracted 3 key sets of limb motions that are described as follows. The first motion was a Whac-A-Mole–like game that involved the abduction of the shoulder (no more than 90°). The second motion was wiping a table and involved external forearm rotation. The third motion was combing one's hair and involved flexion of the shoulder (no more than 90°) (Figures 1-3). This study used the PC-based Oculus Quest 2 head-mounted display (HMD) to provide the most immersive VR experience possible.

Table . Summary of our design principles and strategies based on recommendations for best practices in VR1 (virtual reality phase 1) studies [20].

Design principles and strategies	Our practices
Inspiration through empathy, recruitment, observation, patient interviews, and expert interviews	Two patients with breast cancer who had experienced axillary web syndrome were invited for individual interviews regarding their relevant needs, experiences, fears, and expectations; a group discussion was then conducted to determine the patients' needs.
Ideation through team collaboration, sharing stories and notes, and generating ideas	We analyzed, aggregated, and discussed the stories and data obtained in the previous phase. Our team then formulated 10 ideas for rehabilitation actions. After considering the restrictions on drainage tube indwelling the day after surgery (shoulder joint movement must not exceed 90°), we extracted 3 motions: (1) Whac-A-Mole, which involved abduction of the shoulder; (2) wiping a table, which involved external forearm rotation; and (3) combing one's hair, which involved flexion of the shoulder.
Prototyping through continuous feedback, building a prototype, and repeatedly testing the prototype	We drew the height of a mallet on a wall and placed a picture of a gopher on a table to simulate the Whac-A-Mole game. For the wiping the table and combing hair scenarios, we used a table and a comb, respectively, and we then collected feedback from the patients after their first use. Our team found that the Whac-A-Mole game was difficult to perform owing to the different heights of the patients and seats (eg, a patient may need to raise their shoulder angle excessively to pick up the mallet, leading to pain and an inability to perform the exercise, forcing it to be abandoned). Thus, the software engineer adjusted the height of the controllable mallet and the adjustable gopher table to meet the need of each individual patient.

Study Design

This qualitative study was guided by the phenomenological methodology; it focused on investigating the perceived experience of using VR rehabilitation and then used an inductive approach and the Colaizzi [25] interview data analysis method to identify themes from the VR rehabilitation experiences.

Ethics Approval

Ethical approval for this study was granted by the Human Trials Ethics Committee of Chang Gung Memorial Hospital, Taiwan (202001617A3C501). All the participants provided written informed consent to participate in this study.

Setting

This study was conducted at a medical center in Taiwan that receives up to 20 new patients with breast cancer per month.

Participants and Recruitment

The criteria for participation in this study were as follows: (1) a new diagnosis of breast cancer and being hospitalized for surgical treatment; (2) being aged 20 to 65 years; (3) being able to read and speak Mandarin Chinese or Taiwanese; (4) being willing to use a wearable VR HMD and having sufficient cognitive ability to understand and follow instructions, as well as to interact with the VR environment; (5) having sufficient physical ability (self-reported) to use the VR equipment in the VR rehabilitation program; and (6) being willing to be interviewed. After surgical treatment for breast cancer, patients were invited to a rehabilitation consultation to ask about their willingness to try VR rehabilitation and were recruited to participate in this study. The recruitment period ran from September to December 2021, with 18 patients interviewed.

Data Collection

First, the participants filled out a questionnaires on demographic data (including age, gender, and type of breast surgery), the Distress Thermometer (DT) questionnaire, and the Chinese Health Questionnaire–12 (CHQ-12). The DT is a visual analog scale for routine screening for distress in all patients with cancer; scores range from 0 (indicating no distress) to 10 (indicating extreme distress). A cutoff score of ≥7 is optimal for distress in patients with a new diagnosis [26]. The CHQ-12 was modified from the General Health Questionnaire–12, a widely used psychometric test for screening mental problems, with a score of ≥4 indicating psychological distress [27].

After completing the questionnaires, a face-to-face interview was conducted with each participant for approximately 30 minutes. Interview guides were developed by the research team, which included an expert in qualitative studies and a clinical nurse specialist in breast cancer. After the content of the first interview was analyzed, the interview questions were discussed and modified with the research team.

During the interview process, the researchers actively listened and continuously clarified any perspectives and meanings that the participants wanted to express. Participants were allowed to freely express their views. All interviews were audiorecorded. After the data analysis, the researchers reviewed the data with the patients to ensure data accuracy and completeness.

Inductive Content Analysis

According to Kyngäs [28], an inductive approach, which is common in qualitative research, should be used when no prior research has addressed a specific phenomenon or if existing knowledge is fragmented. Because prior studies had not investigated the experiences of patients with breast cancer to evaluate the effectiveness of VR-based rehabilitation, our study used an inductive approach to content analysis, which involved data reduction, data grouping, and, finally, concept formation. The content was analyzed with the Colaizzi [25] phenomenological analysis method, which involves a 7-step procedure for content analysis. Specifically, 3 researchers analyzed the data and grouped them into themes to enhance comprehension. First, the interview transcript was read to obtain an idea of its overall meaning. Second, a researcher extracted significant statements relevant to the purpose of the study. Third, each statement considered meaningful was recorded for accurate representation of the research data. Fourth, the researcher classified significant statements into categories based on their meaning. Fifth, the researcher grouped similar categories together and organized them into themes. Sixth, all themes presented were combined to produce an exhaustive description. Seventh, the results were presented to each participant for feedback and to verify their accuracy.

Trustworthiness

To enhance the trustworthiness of our study, we referred to the Guba and Lincoln [29] quality criteria of credibility, transferability, dependability, and confirmability.

To establish confidence in the credibility of the findings, triangulation was used to examine the consistency of the data. Researchers presented their summaries of the categories and themes from data analysis and discussed any uncertainty about any category or theme by replaying and reanalyzing the interview recording.

High transferability was ensured through the interview process, including the stability of observations and the interrater reliability. As an interviewer, the researcher was attentive to the interviewees' experiences and avoided bias arising from their values and beliefs. The interviewer was conscious about avoiding misperceptions about what the interviewees were saying to ensure the stability of observations. There was only 1 interviewer, hence interrater reliability was not measured.

The study had high dependability, as the data collecting procedures were approved by an expert in qualitative methodology, and the themes and subthemes that emerged were consistent among all researchers after the coding and recoding procedure during the data analysis.

Finally, during the data analysis stage, 3 researchers who were not part of the study team confirmed the collected data by distinguishing between the units of the main themes and subthemes to verify the main themes' theoretical saturation and thus achieved confirmability.

Results

Characteristics of Participants

Table 2 shows the participants' characteristics. The mean age of the participants was 46.66 (SD 8.05) years; 17 participants were female (95%) and 1 was male (5%); 11 were married (61%); 11 (61%) were full-time workers; and 7 (39%) were housekeepers or had no formal employment. Regarding the types of surgery received, 9 participants (50%) underwent mastectomy and sentinel lymph node biopsy, 4 (23%) underwent mastectomy and axillary lymph node dissection, 2 (11%) underwent mastectomy and reconstruction, and 3 (16%) underwent modified radical mastectomy. All participants had DT scores less than 7, indicating no distress. In the CHQ-12 items, some participants reported having shaking or numbness of limbs (n=3, 17%), losing a great deal of sleep because of worry (n=4, 22%), and losing confidence in themselves (n=4, 22%) (items 4, 5, and 8). However, all participants had CHQ-12 scores less than 4, indicating no mental problems. Finally, 7 (39%) and 11 (61%) of the participants reported moderate (4-6) and mild (1-3) wound pain on the Numeric Rating Scale for Pain, respectively.

Table . Distribution of sociodemographic variables of participants (N=18).

Variables		Participants, n (%)
Sex		
	Female	17 (95)
	Male	1 (5)
Age group (years)		
	35-44	6 (33)
	45-54	8 (44)
	55-64	4 (3)
Educational level		
	Senior high school	9 (50)
	College	9 (50)
Distress		
	Yes (DT[a] score ≥7)	0 (0)
	No (DT score <7)	10 (100)
Mental problems		
	Yes (CHQ-12[b] score ≥4)	0 (0)
	No (CHQ-12 score <4)	18 (100)
Numerical Rating Scale for Pain score		
	1-3	11 (61)
	4-6	7 (39)
Marital status		
	Married or in a domestic partnership	11 (61)
	Single	5 (28)
	Separated or divorced	2 (11)
Employment status		
	Employed	11 (61)
	Unable to work	7 (39)
Type of breast surgery		
	Mastectomy with sentinel lymph node biopsy	9 (50)
	Mastectomy with axillary lymph node dissection	4 (23)
	Mastectomy with reconstruction	2 (11)
	Modified radical mastectomy	3 (16)

[b]CHQ-12: Chinese Health Questionnaire–12.

Themes

The following 3 themes were inductively extracted from the interview data: (1) VR was powerful in facilitating rehabilitation, (2) early and repetitive upper limb movements were an advantage of VR rehabilitation, and (3) extensive VR use had challenges to be overcome. Tables 3-5 present these themes in greater detail alongside their subthemes and interviewee statements.

Table . Subthemes and interviewee quotes related to theme 1: virtual reality (VR) was powerful in facilitating rehabilitation.

Subthemes	Quotes
Obtaining knowledge	• "It turns out that some actions are unsuitable [because of the drainage tube]; after use, I have a better idea of the angle of movement" (participant 2). • "After practicing with this system [VR] and being discharged from the hospital, I know that some actions are not suitable for me to do, so I will not do them randomly" (participant 3). • "I was anxious, thinking that not moving my arms was suitable for wound healing" (participant 13). • "I can adjust my range of motion according to my tolerance, and I will not feel frustrated" (participant 17).
Companionship	• "This way of rehabilitation [VR] is like a kind of support for me when exercising because thephysiotherapist does not always accompany me" (participant 9). • "The usage process is very simple. I think it is well executed in the hospital and I can concentrate on practicing" (participant 5). • "The physiotherapist was very busy and left after teaching me the rehabilitation movement, so I had to do it independently" (participant 11). • "I didn't understand what this was at first, and I was a little scared, but it turned out that I was doing rehabilitation while playing games" (participant 1).

Table . Subthemes and interviewee quotes related to theme 2: early and repetitive upper limb movements are an advantage of virtual reality (VR) rehabilitation.

Subthemes	Quotes
Reduced fear of movement	• "The VR rehab game method is more fun than the traditional rehab method because it lets me know I need to do rehab exercises; I think I can do it a few more times" (participant 1). • "My time in the hospital was short, and it was a pity that I didn't do VR many times" (participant 6). • "I experienced no pain or discomfort during the VR rehab; I want to do it a few more times" (participant 7). • "After playing Whac-A-Mole, I attempted to move my arm" (participant 11). • "While using it, I temporarily forgot that I had surgery" (participant 14). • "Initially, I was terrified of moving my arms, but now, I'm having so much fun that I don't realize I'm doing rehab" (participant 18).
Enhanced motivation to engage in rehabilitation	• "The VR program can be performed as soon as possible; I have been performing VR for seven days since surgery. In the execution of the Whac-A-Mole and wiping the table exercises, I did not have too much discomfort or pain, and I am doing better and better" (participant 15). • "Although there is no VR at home, I can continue to do the VR movements, and I will not worry about my arm's limited range of motion in the future" (participant 16). • "After using VR for rehabilitation, I found that my condition was not as bad as I thought" (participant 7).

Table . Subthemes and interviewee quotes related to theme 3: extensive virtual reality (VR) use has challenges to be overcome.

Subthemes	Quotes
Safety of the real-world environment	• "I was initially scared because I had never used VR" (participant 4). • "Wearing a VR HMD, I can't see the outside world, so I'm worried about hitting something" (participant 5).
Cost of virtual reality rehabilitation equipment is too high to extend to home use	• "VR rehabilitation equipment is too expensive to buy and can only be used in hospitals" (participant 5). • "Without equipment, there is no way to use VR for rehabilitation" (participant 8). • "VR rehabilitation can only be used in hospitals; at home, we use traditional rehabilitation methods" (participant 17). • "I hope to rent VR equipment for my home so I can use it anytime" (participant 18). • "Although there is the Switch, finding a suitable sports game for rehabilitation is difficult" (participant 9).
Motion sickness	• "After wiping the table, I felt a little dizzy" (participant 10). • "My eyes constantly roll when wiping the table, which is a little uncomfortable" (participant 9).

VR Was Powerful in Facilitating Rehabilitation

Overview

A key concept of this inductive theme was the "power" obtained from knowledge and companionship. Related subthemes and interviewee statements are presented in Table 3.

Obtaining Knowledge

A total of 12 (70%) of the participants described how the VR content helped them learn the most helpful rehabilitation movements and the angular limitations of their exercises and thus enabled them to perform these exercises safely and relatively early in the rehabilitation process.

Companionship

Most of the participants stated that playing games enabled them to feel as though they were interacting with health care professionals and experiencing companionship and support.

Early and Repetitive Upper Limb Movements: An Advantage of VR Rehabilitation

Overview

After surgical treatment for breast cancer, rehabilitative exercises must be performed early. In this study, wound pain and discomfort during such exercises were the main concerns of the participants, leading to fear of movement. Related subthemes and interviewee statements are presented in Table 4.

Reduced Fear of Movement

A total of 14 (80%) of the participants stated that the gamified design of VR rehabilitation made it more interesting than traditional rehabilitation, while 7 of the patients experienced moderate pain after surgery. However, during the use of VR for rehabilitation, these patients reported no wound pain or discomfort. In addition, their willingness to engage in rehabilitation was enhanced by the second day after surgery.

Enhanced Motivation to Engage in Rehabilitation

Most of the participants described an immersive virtual environment that facilitated the performance of early rehabilitative exercises. In addition, the participants were subsequently able to continue performing the aforementioned 3 rehabilitation movements at home without VR.

Extensive VR Use Has Challenges to Be Overcome

Overview

Most of the patients had safety concerns, mainly because while wearing the VR HMD, they were unable to pay attention to the environment around them. Consequently, some of the patients initially felt apprehensive, fearing collisions with nearby objects. In addition, high equipment costs limited the accessibility of the equipment for home use, and many of the patients expressed disappointment that they were able to use the system only in hospital. Related subthemes and interviewee statements are presented in Table 5.

Safety of the Real-World Environment

While the patients were wearing the VR HMD and engaging in VR-based exercise, they were unable to pay attention to the environment around them. Thus, patients had the not-unfounded fear that they might collide with nearby objects and were initially apprehensive. Therefore, patients should be in a clutter-free environment when engaging in VR rehabilitation.

Cost of VR Rehabilitation Equipment Is Too High to Extend to Home Use

The cost of VR equipment for rehabilitation is high, making it relatively inaccessible for home use. Each new technology faces the problem of high equipment cost in its initial stage, and similarly, the main problem for most of the participants in this study was that they wanted to continue using the rehabilitation equipment at home. They indicated that they thought it was a pity that the system could be used only in hospital.

Motion Sickness

We found that 3 of the participants reported the side effect of motion sickness after performing the wiping table exercise.

Discussion

Principal Findings

To the best of our knowledge, this study is the first phenomenological study to investigate the feasibility of an immersive VR experience for facilitating postoperative rehabilitation in patients with breast cancer. Through inductive thematic analysis, our study found VR to be an effective and suitable intervention for our patient population. Tables 3 and 4 address feasibility in relation to 2 of the 3 inductive themes of this study: "VR was powerful in facilitating rehabilitation" and "early and repetitive upper limb movements are an advantage of VR rehabilitation." Table 5 reveals the key finding that the high costs of VR hardware and software limit its at-home use. These results further support the recommendations of the VR CORE group [20]. However, the high cost of VR equipment remains a concern.

VR Was Powerful in Facilitating Rehabilitation

This study found that "power" was an essential concept and that power was cultivated through knowledge and companionship. One key finding related to this inductive theme was the knowledge obtained by the individual. In our study, most of the participants were skeptical about their early postoperative rehabilitation, and some had no idea how to proceed with it; however, through VR, these patients gained information about rehabilitation, which then led to behavioral changes. A previous study noted the importance of people's need to know which approach they should adopt to improve their health [30]. In addition, most patients with breast cancer desire information concerning recovery details; in particular, they want real-time, transparent information regarding appropriate rehabilitative measures [21]. Our findings were consistent with those of the 2 aforementioned studies. Another present finding was related to companionship; specifically, the participants reported that they felt as if a medical care team was with them in their rehabilitation in the VR world. This finding is notable because not every patient with breast cancer receives a rehabilitation exercise consultation after surgery. Our interactive VR system provides clear information regarding the commencement and completion of rehabilitation exercises, and its prompts align with how the clinical rehabilitation program operates (eg, 20 prompts for each motion). The literature notes that an ideal user experience must include interaction with VR applications in order to encourage and support users to complete clinical activities; this assertion is consistent with our findings [31].

Early and Repetitive Upper Limb Movements: Advantage of VR Rehabilitation

VR elicited engagement in early postoperative rehabilitation in most of this study's patients, seemingly stemming from their reduced fear of movement and their enhanced motivation. Early postoperative rehabilitation in patients who have undergone breast cancer surgery aims to improve shoulder mobility, arm mobility, or both. VR is believed to be as effective as conventional physiotherapy in improving upper limb function to facilitate the maintenance of activities of daily living [32]. Some of the participants in this study were initially apprehensive to undertake postoperative rehabilitation primarily because of fear related to insufficient knowledge of the appropriate degree of movement. Nevertheless, our VR rehabilitation system was based on the concept of gamification; the participants who used the system were attracted to the game screen, and consequently, their negative feelings—including fear, pain, and discomfort—were temporarily alleviated. In this manner, the VR system considerably enhanced the participants' motivation to engage in rehabilitation; this finding was consistent with those of previous studies [18,33]. In addition, the game design can be adjusted according to the needs of the patient to prevent patients from giving up on movements that are either difficult or so simple that the desired training outcomes cannot be achieved by performing them.

Challenges of Extensive VR Use to Be Overcome

The participants in this study were required to wear HMDs; thus, they could not see their surroundings during rehabilitation. Related studies that have recommended VR have stated that when using such technology, a space of at least 70 cm × 70 cm is required; however, in our study, the participants took a seated position to minimize the risk of tripping and thus needed only to pay attention to whether the seat back was affecting exercise safety. Although research has shown that the cost of HMDs has fallen in recent years [15], VR devices remain unaffordable for many people in Taiwan. Therefore, even if patients with breast cancer are interested in using this emerging technology for rehabilitation, doing so without an HMD is difficult. In addition, the development and maintenance costs of VR software and hardware are high, and thus, the cost of VR equipment remains a challenge for large-scale implementation in postoperative rehabilitation.

Motion sickness (MS) is a common physiological response to VR immersion [34]. Previous studies have shown that behavioral and dietary strategies and physical therapy, such as listening to music or chewing gum [35], are effective in alleviating MS symptoms. Although each movement in our VR rehabilitation system was accompanied by music with a brisk tempo, 3 of the patients in this study still experienced MS due to unsuitable seat height. A previous study demonstrated that positive emotions can relieve MS [36]; we found that most patients have positive emotions while using VR for rehabilitation. Accordingly, this paper suggests that the use of VR should be combined with emotional assessments to effectively prevent MS. With regard to feasibility, we found that the present VR system met the patients' needs, conformed to their values, and satisfied their expectations. The system also provided an engaging and interactive rehabilitation environment that stimulated the patients' motivation to engage in early and continuous rehabilitation and, in turn, reduced their risk of developing defensive functional impairments. Nevertheless, the accessibility of VR proved to be a challenge because of the difficulty of using VR technology at home. Thus, such interventions may tend to be limited to in-hospital use because not every patient can afford to purchase VR equipment and software.

Study Limitations

This study has some limitations. First, we did not conduct a pilot study of the interview guide. However, after the content of the first interview was analyzed, the interview questions were discussed and modified with the research team to identify and address any potential issues in the data collection methods. It may be recommended to incorporate a pilot study in future research to ensure validity and robustness. Second, the development of VR technology to facilitate postoperative rehabilitation in patients with breast cancer is still in its infancy. In this study, only 3 rehabilitation exercises were developed and clinically tested. The facilitators of and barriers to rehabilitation were investigated. To determine the clinical efficacy of the proposed VR system, a large-scale randomized controlled trial is needed.

Conclusion

Feasibility research related to health care is crucial for generating novel ideas and improvements to provide more effective care for patients. From the perspective of this study, rehabilitation is an iterative, active, and educational process of problem-solving that must focus on a patient's behavior. VR technology was effective in facilitating rehabilitation by providing knowledge and companionship to participants. It helped reduce fear of movement and enabled early and repetitive upper limb movements. However, safety concerns, high equipment costs, and potential side effects like MS were reported as challenges to extensive VR use.

Acknowledgments

We are grateful to Mei-Ling Li and Su-Fang Li in for their informative comments during the development of the virtual reality rehabilitation system. This research was partially supported by Kaohsiung Chang Gung Memorial Hospital, part of the Chang Gung Medical Foundation, Taiwan (grant CMRPG8L0081), for the development of the virtual reality system and partially supported by the China Medical University Project (grant CMU108-MF-21).

Authors' Contributions

SCW and CWC were responsible for the study design and coordination. CWC, HHS, and CFL extracted the data. SCW and WCL drafted the manuscript. All authors have contributed to, read, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic has challenged the mental health of health care workers, increasing the rates of stress, moral distress (MD), and moral injury (MI). Virtual reality (VR) is a useful tool for studying MD and MI because it can effectively elicit psychophysiological responses, is customizable, and permits the controlled study of participants in real time.

Objective: This study aims to investigate the feasibility of using an intervention comprising a VR scenario and an educational video to examine MD among health care workers during the COVID-19 pandemic and to use our mobile app for longitudinal monitoring of stress, MD, and MI after the intervention.

Methods: We recruited 15 participants for a compound intervention consisting of a VR scenario followed by an educational video and a repetition of the VR scenario. The scenario portrayed a morally challenging situation related to a shortage of life-saving equipment. Physiological signals and scores of the Moral Injury Outcome Scale (MIOS) and Perceived Stress Scale (PSS) were collected. Participants underwent a debriefing session to provide their impressions of the intervention, and content analysis was performed on the sessions. Participants were also instructed to use a mobile app for 8 weeks after the intervention to monitor stress, MD, and mental health symptoms. We conducted Wilcoxon signed rank tests on the PSS and MIOS scores to investigate whether the VR scenario could induce stress and MD. We also evaluated user experience and the sense of presence after the intervention through semi–open-ended feedback and the Igroup Presence Questionnaire, respectively. Qualitative feedback was summarized and categorized to offer an experiential perspective.

Results: All participants completed the intervention. Mean pre- and postintervention scores were respectively 10.4 (SD 9.9) and 13.5 (SD 9.1) for the MIOS and 17.3 (SD 7.5) and 19.1 (SD 8.1) for the PSS. Statistical analyses revealed no significant pre-to postintervention difference in the MIOS and PSS scores (*P*=.11 and *P*=.22, respectively), suggesting that the experiment did not acutely induce significant levels of stress or MD. However, content analysis revealed feelings of guilt, shame, and betrayal, which relate to the experience of MD. On the basis of the Igroup Presence Questionnaire results, the VR scenario achieved an above-average degree of overall presence, spatial presence, and involvement, and slightly below-average realism. Of the 15 participants, 8 (53%) did not answer symptom surveys on the mobile app.

Conclusions: Our study demonstrated VR to be a feasible method to simulate morally challenging situations and elicit genuine responses associated with MD with high acceptability and tolerability. Future research could better define the efficacy of VR in examining stress, MD, and MI both acutely and in the longer term. An improved participant strategy for mobile data capture is needed for future studies.

Introduction

Background

The COVID-19 pandemic has exerted unprecedented strain on health care workers (HCWs) globally [1]. Frontline HCWs have been forced to make difficult medical decisions that are contrary to their moral and professional principles and to work in conditions where they cannot meet standards of quality care [2,3], which has put them at a greater risk of experiencing moral distress (MD) than possibly ever before [4,5]. Distressing situations such as being forced to deal with a shortage of personal protective equipment and having to prioritize who will receive life-sustaining treatment have become common during the pandemic. For HCWs, experiencing such situations may cause significant emotional burden and induce the phenomenon of MD [6-8]. MD is defined as distress stemming from the inability to enact actions believed to be morally right owing to external constraints [8,9]. Moral injury (MI), an extreme form of MD, can occur when individuals witness or perpetrate actions that violate deeply held moral beliefs, resulting in severe emotional reactions with long-lasting consequences [7]. However, further investigation is needed to enable a more precise distinction between MD and MI [7].

The first description of MI was made in the military context by Shay [10] and was defined as a betrayal of moral character, usually as a result of the actions of a person in a position of authority [10], leading to feelings of powerlessness, helplessness, and loss of faith in humanity [7,10]. Shay [11] argues that MI occurs when the following conditions are met: (1) there has been a betrayal of what is considered right (2) by someone holding legitimate authority and (3) in high-stakes situations. Litz et al [12] expanded the concept of MI to include “the lasting psychological, biological, spiritual, behavioral, and social impact of perpetrating, failing to prevent, or bearing witness to acts that transgress deeply held moral beliefs and expectations.” As part of the definition, the authors also defined potentially morally injurious events (PMIEs) as the acts of perpetrating, failing to prevent harm, or bearing witness to acts that transgress deeply held moral beliefs [12]. Experiencing a PMIE is frequently associated with feelings of betrayal, guilt, shame, and self-blame [13]. Furthermore, PMIEs may not only cause acute MD but can also have long-term consequences because MD and MI may develop weeks or months after a PMIE [14].

MI was originally associated with, and frequently co-occurs with, posttraumatic stress disorder (PTSD) [13], which has been conceptualized as a fear-related disorder [15,16]. However, MI has not yet been defined in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition [16], and a PMIE does not necessarily fulfill the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition criterion A for PTSD. The concept of MI was conceived to encompass the following criteria, among others: (1) reexperiencing self-referential moral emotions (eg, anger, guilt, and shame); (2) strong negative beliefs about the self, the world, and others; and (3) self-destructive behaviors that inflict severe distress or functional impairment [17,18]. In addition, emerging literature has defined MI as being mechanistically different from PTSD [13,15]. A positron emission tomography study in veterans with PTSD showed that regional blood glucose metabolism differed according to the nature of traumatic exposure as follows: the group with PTSD owing to danger-based traumas (ie, life-threatening events) showed higher metabolism in the amygdalae; by contrast, the group with PTSD secondary to non–danger-based traumas (eg, MI by self or others) had increased metabolism in the precuneus [19], a region that has been associated with the processing of self-referential feelings (eg, shame and guilt) [15]. Therefore, further research is needed to determine the ecological validity of MI as an independent diagnostic category [13]. In addition, there is a need to investigate specific interventions for MI because it has been found to not generally respond to evidence-based treatments for PTSD [12,17]; for example, moral resilience training, the development of emotional intelligence skills, and strategies for promoting moral repair have already been proposed as specific treatments for MI and are currently under investigation [5,17,20].

Although MI has been largely studied in military contexts [17], it is also applicable to HCWs, particularly in light of the COVID-19 pandemic. However, MI and PMIEs are poorly understood in this context. Čartolovni et al [7] argue that MI occurs in HCWs when they experience PMIEs involving high-stakes situations that are beyond their control. To investigate MI in the COVID-19 context, Rushton et al [5] conducted a survey with frontline HCWs and reported an overall prevalence rate of 32% for MI, with nurses being the most affected (38%). Fewer years of experience were positively associated with MI, whereas religious affiliation or spirituality and higher levels of moral resilience were associated with lower MI scores. In addition, the study showed a moderate correlation between MI and various ethically challenging situations, such as experiencing negative consequences at work after expressing safety concerns, working with limited resources, and carrying out decisions of others which threaten one's own values [5].

Litam and Balkin [4] examined the relationship between MI and the professional quality of life in a convenience sample of HCWs during the COVID-19 pandemic. The authors reported that secondary traumatic stress was a strong predictor of MI in frontline HCWs, but the contribution of compassion, satisfaction, and burnout to MI scores was nonsignificant. Of note, nurses had significantly higher burnout scores than physicians. Zerach and Levi-Belz [21] conducted a survey to investigate the patterns of exposure to PMIEs in a sample of HCWs and social care workers during the COVID-19 pandemic. The prevalence rate of symptoms of MI was 40%, with betrayal events being the most frequent PMIEs with a prevalence rate of 62%. In general, exposure to PMIEs was positively related to perceived stress, depression, anxiety, and self-criticism, whereas it was negatively associated with self-compassion. Interestingly, the duration of care for patients with COVID-19 was not associated with MI [21].

To increase the ecological validity of MI as a diagnostic entity, the experiences of the MD-MI continuum should be examined using accurate methods [13]. To date, several measurement instruments have been developed to identify MI outside of military contexts, including the Moral Injury Symptom Scale–Healthcare Professionals version [22] and the Moral Injury Outcome Scale (MIOS) [18]. The MIOS is a self-rated scale, developed as an assessment tool to evaluate MI as a multidimensional outcome [18]. This scale comprises 10 binary (*yes* or *no*) questions and 15 five-point Likert scale questions about experiencing a PMIE and feelings associated with this event; higher scores indicate greater severity of MI symptoms. At the end, the MIOS has an additional 7-point Likert scale question that assesses the extent to which the experience of PMIEs has interfered in one's self-care or caused functional impairment (from *not at all* to *extremely*). The MIOS is in the final stage of development by the MIOS Consortium [18].

Conducting interventional studies to investigate the impact of PMIEs on mental health in real-world settings is challenging owing to operational constraints. This is especially true in health care, where limitations imposed by patient privacy regulations may make traditional clinical trials in MI impractical. Another important aspect to consider is the ethical implications of submitting an already strained workforce to moral stressors in an uncontrolled real-world environment such as an intensive care unit (ICU). A promising strategy to address these limitations is the use of virtual reality (VR) scenarios. VR is a powerful technology for examining mental health and the MD-MI continuum because it offers several advantages over traditional observational research in naturalistic environments. First, VR allows researchers to observe, monitor, and potentially support participants in fully controlled environments in real time [23]; therefore, it is safer and provides more accurate measures of one's reactions to ethically challenging situations compared with observational studies in naturalistic environments. Second, VR allows for the design of fully customizable scenarios [23], making it especially suitable to simulate real-world scenarios in health care that otherwise would be impractical to replicate. As traumatic events in both PTSD and MI are highly idiosyncratic, and treatment for PTSD requires exposure to individual cues, we assume that virtual environment customization should be a critical feature to provide personalized and effective interventions to treat MD and MI [24]. In addition, extensive evidence has demonstrated the effectiveness of VR-based interventions for PTSD [25-27]. Third, VR environments can effectively elicit real psychophysiological responses because individuals are immersed in virtual scenarios as if these were real events, with the advantage of enabling real-time data capture [23,24]. All these advantages make VR-based trials ideal to study the MD-MI phenomena in HCWs. However, no prior research has investigated the feasibility of VR interventions to examine MD and MI in the context of the COVID-19 pandemic.

Objectives

The overarching goal of this study was to determine the feasibility of using a compound VR intervention to examine MD and MI among HCWs during the COVID-19 pandemic. To achieve this, we designed a VR scenario in which HCWs faced a morally challenging situation in a midpandemic hospital environment while being monitored for acute psychological and physiological measures of stress. As outlined in our protocol paper [28], our aims were to (1) evaluate the feasibility of using a VR scenario to simulate the experience of a COVID-19–related morally challenging event by using measures of tolerability, dropouts, and suitability of the virtual scenario; (2) assess the potential of our VR scenario to elicit mild stress and MD, as measured by quantitative self-report questionnaires as well as qualitative analyses of semistructured interviews; and (3) investigate the feasibility of our novel mobile app (*DiiG App*) for longitudinal monitoring of stress and MD in naturalistic settings in the 8 weeks after the intervention.

On the basis of the findings with PTSD [25-27], we hypothesized that VR scenarios would be a feasible method for assessing MD and MI. Given the ability of VR to generate genuine responses, we additionally hypothesized that our virtual scenario would significantly increase stress levels and elicit feelings and symptoms associated with MD and MI. Finally, we hypothesized that our mobile app would successfully capture symptoms associated with stress and MD in the 8-week follow-up.

To the best of our knowledge, this pilot study is the first to assess the feasibility of using a VR scenario to simulate the experience of a morally challenging event related to the

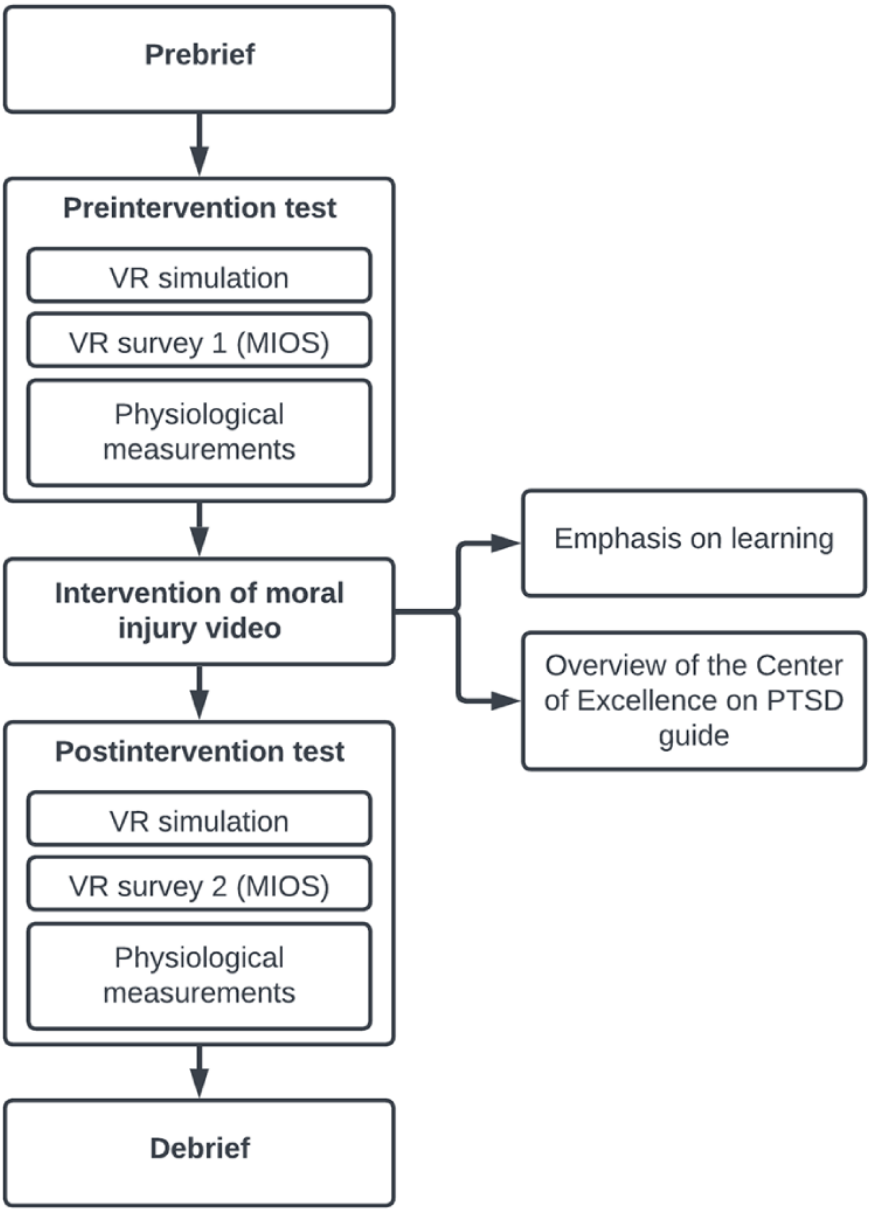
COVID-19 pandemic by HCWs while assessing its acute perceptual, psychological, and physiological effects in real time.

Methods

Study Design

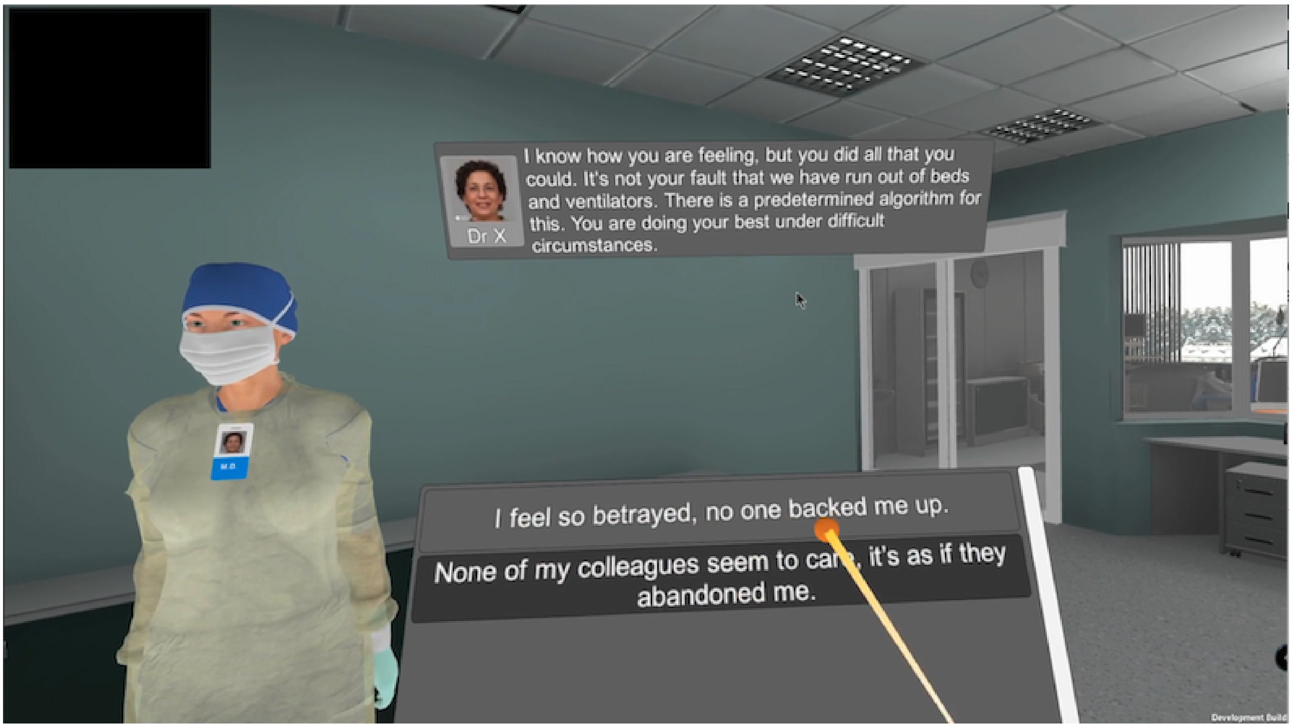
In this single-cohort pilot study (ClinicalTrials.gov: NCT05001542), we adopted a multimethod approach in a pretest-posttest design to develop a compound intervention consisting of three successive parts: (1) a VR scenario to simulate a morally complex situation, (2) an educational video on MI and appropriate mitigation strategies, and (3) a repetition of the VR scenario. The intervention was followed by longitudinal data collection of mental health and MI surveys using our mobile app. The MI educational video was based on the Center of Excellence on PTSD guide [29] that summarized the causes and identifiers of MI and potential interventions to mitigate MD. The effectiveness of the VR-based educational intervention was assessed using the MIOS [18], the Perceived Stress Scale (PSS) [30], and the Igroup Presence Questionnaire (IPQ) [31]. The PSS is a self-reported measure of stress, whereas the IPQ evaluates the experience of presence during the VR scenario. As previously mentioned, the MIOS is a self-rated scale that was developed as an assessment tool to evaluate MI. For the purposes of this pilot study, we adopted a brief version of the MIOS (hereinafter referred to as *the MIOS*), which comprises 10 five-point Likert scale questions and 4 binary (*yes* or *no*) questions [32]. During the VR scenario, respiratory impedance, electrocardiography (ECG), galvanic skin response, and photoplethysmography were continuously collected. In addition to the original signals, we extracted the derivation of these signals, including ECG pulse rate, ECG RR interval, respiratory rate, and elevated respiratory rate. A visualization of the VR experimental flow can be seen in Figure 1. Further details on the intervention and data collection have been explained and outlined in the paper by Nguyen et al [28].

Figure 1. Flowchart of the virtual reality (VR) experiment. MIOS: Moral Injury Outcome Scale; PTSD: posttraumatic stress disorder.



The experimental session was divided into prebrief, preintervention test, intervention video, postintervention test, and debrief components (Figure 1). The preintervention test and postintervention test were conducted in VR, whereas the prebrief and debrief occurred outside the virtual environment. The MIOS was performed at 4 time points as follows: as a paper-based version for the prebrief and debrief and in the virtual scenario for the preintervention test and postintervention test. The PSS was performed twice, at prebrief and debrief. The MIOS and the PSS focus on symptoms of MD and stress, respectively, over the last month. However, when answering these scales, participants were told to rate symptoms at that exact moment. The goal of the prebrief was to explain how the physiological data would be collected and prepare the participant for the VR scenario; it consisted of an orientation to the virtual space and equipment, safety precautions, and the expected outcome of the study. During the preintervention test, participants were immersed in the VR scenario where they took on the role of a physician in an ICU during the COVID-19 pandemic. To experience the VR scenario, participants used a VR headset and 2 wireless controllers that tracked their head and hand movements, mapping it to an avatar. Semitranslucent panels were displayed as spatial elements in the VR scenario (Figure 2), providing information to the participant in the form of the dialogue panel (which displayed the current nonplayable character's photograph, name, and the text version of the dialogue being spoken) and the interaction panel (which displayed a list of available choices and responses for the participant to choose from).

Figure 2. User interface displaying the dialogue and interaction panels.



In the scenario, a shortage of life-saving equipment resulted in the decision to move a ventilator from 1 patient to another patient who had a greater chance of survival. After being informed of this, the participant's avatar appeared in the next scene, where they had to communicate this decision to the first patient's family and respond to the family's reactions of frustration and anger. After completing the preintervention test and while still immersed in the VR scenario, participants watched a brief 2D educational video comprising key concepts of MD and MI and adaptive behaviors to cope with morally complex situations at the individual, team, and organizational levels. Participants then completed the postintervention test, which consisted in a repetition of the VR scenario played in the preintervention test. Finally, in the debrief, participants were asked open-ended questions to encourage them to describe their experiences in the virtual setting, followed by an exit survey [28].

After the experiment, participants were instructed to use our mobile app [33] to collect passive and active data for distress monitoring during the following 8 weeks. As MI may have a delayed onset, such data collection allows for longer-term monitoring of emotions associated with MD, offering insights into the distress experienced in real time.

Participants

Participants were recruited and enrolled between May 2021 and August 2021 from the 3 affiliated hospitals at Unity Health Toronto. Participants were enrolled if they were an HCW currently providing health care at their respective hospital of employment, aged ≥18 years, and owned a mobile phone (an Android mobile phone with operating system version 6.0 or above or an iPhone with operating system version 11.0 or above).

Statistical Analysis

As this was a pilot feasibility trial, we summarized dropout rates, easiness of use, tolerability, acceptability, and utility using counts and percentages. Continuous data were summarized using range, mean and SD, and median and IQR. To assess the effect of the VR scenario on symptoms of MI, we compared MIOS scores across the 4 time points using a Friedman test. In addition, follow-up MIOS scores were compared with the score at prebrief using Wilcoxon signed rank tests with Bonferroni correction (.05/3=.0167) to adjust for multiple comparisons. As PSS scores were collected only at 2 time points (ie, at prebrief and debrief), a Wilcoxon signed rank test was used to compare the difference in the PSS scores between these 2 time points. A *P* value of <.05 was considered significant unless otherwise specified. We performed statistical analysis using SAS 9.4 (SAS Institute Inc).

Quantitative Analysis

Stress and MD Analysis

In this feasibility study, we piloted the application of the MIOS to assess MD both acutely and longitudinally. As mentioned in the *Study Design* section, MIOS was administered during the prebrief, preintervention test, postintervention test, and debrief. Participants were also prompted to complete MIOS on the mobile app in the 8 weeks after the intervention for a longitudinal assessment of MD and MI. All questionnaires used in the mobile app (eg, the MIOS and the PSS) are available in the appendices of the study by Nguyen et al [28].

IPQ Assessment

To objectively assess user experience within the VR scenario, we adopted the IPQ, which is a questionnaire for measuring the sense of presence experienced in a virtual environment [31]. Composed of 14 questions (answered on a 6-point Likert scale), the IPQ has a high reliability (Cronbach α=.87) and outputs four items (1 general item, not belonging to a subscale, and 3 subscales): (1) general presence (sense of being there), (2) spatial presence (the sense of being physically present in the virtual environment), (3) involvement (measuring the attention devoted to the virtual environment), and (4) experienced realism (measuring the subjective experience of realism in the virtual environment).

Hereinafter, the 4 outputs will be referred to as *IPQ components*. More information about the construction and structure of the scale and the IPQ's reliability analysis is available on the Igroup project consortium website [34,35].

Mobile Data Analysis

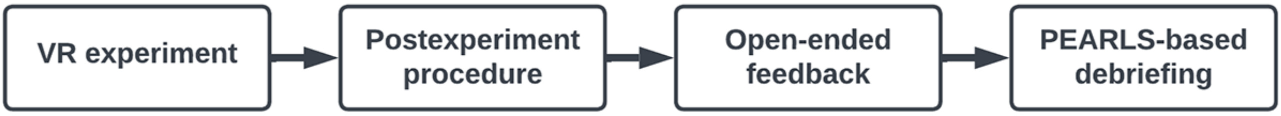
After participating in the intervention, participants were instructed by our research staff to download and regularly use our mobile app to answer surveys in the 8-week follow-up. Participants received push notifications on the mobile app 3 times weekly to answer short versions of the scales related to depression (2-item Patient Health Questionnaire), anxiety (2-item Generalized Anxiety Disorder), stress (4-item PSS) MI (4-item MIOS), and loneliness (3-item University of California Los Angeles Loneliness Scale). With the exception of the 3-item University of California Los Angeles Loneliness Scale, participants were also asked to answer the full version of these scales once weekly. Short versions of the scales were used on weekdays to minimize participant burden. The mobile app also had the option of collecting passive data from built-in smartphone sensors (GPS and accelerometer) from participants who provided in-app consent to gather information on distance traveled and activity patterns. Details on the mobile data collection were previously overviewed in the study by Nguyen et al [28]. We used in-app automated survey reminders to promote app use.

Qualitative Analysis

Content Analysis

We performed a content analysis on the data collected from the scenario debriefing conducted immediately after the compound intervention. Qualitative content analysis is a method to interpret meaning from text data and draw conclusions from words, themes, or concepts that occur in the text, in reference to their context, so that research questions can be answered [36]. We used inductive category development by becoming immersed in the data and allowing insights on categories to emerge from the data [37]. The scenario debriefing consisted of a semistructured interview that allowed participants to answer open-ended questions about their overall experience, followed by a semistructured debriefing methodology (the interview guide is included in Multimedia Appendix 1). The researchers (BN and AT) who collected the VR data were trained using the Promoting Excellence and Reflective Learning in Simulation (PEARLS) health care debriefing tool [38], a simulation debriefing framework to help learners assess their experience within a safe environment. A flow diagram of the debriefing can be seen in Figure 3. After completion of the intervention, we conducted a postexperiment procedure, which consisted of removing the VR headset from the participant but keeping the physiological sensors attached. In addition, we confirmed with the participant that they were able to continue with the debriefing.

Figure 3. Flow diagram of the debriefing. PEARLS: Promoting Excellence and Reflective Learning in Simulation; VR: virtual reality.



During the open-ended feedback part of the debrief, we asked participants to speak freely about their experience with the experiment. We specifically asked the following questions:

1. "What suggestions or feedback would you give to improve the scenarios? Please comment on what can be improved, what can be more realistic, and any deviation from real-life applications."
2. "Could you share something that you have learned about moral injury today? How might this apply to your clinical practice?"

The research questions we sought to answer with our content analysis from this feedback were as follows:

1. "How can the VR scenario be improved?"

2. “How accessible and relevant was our intervention?”

We subsequently conducted scenario-based debriefing using the PEARLS [38] methodology, which involved an exploration of the following predetermined topics: participant experience with the technology used, decision-making during the scenario, and emotions elicited during the scenario. The research questions we sought to answer with the content analysis from the scenario-based debriefing were as follows:

1. “What is the overall user experience of participants with the VR technology?”
2. “What were the determining factors for the decisions that participants made in the scenario?”
3. “How did the scenario make the participant feel?”

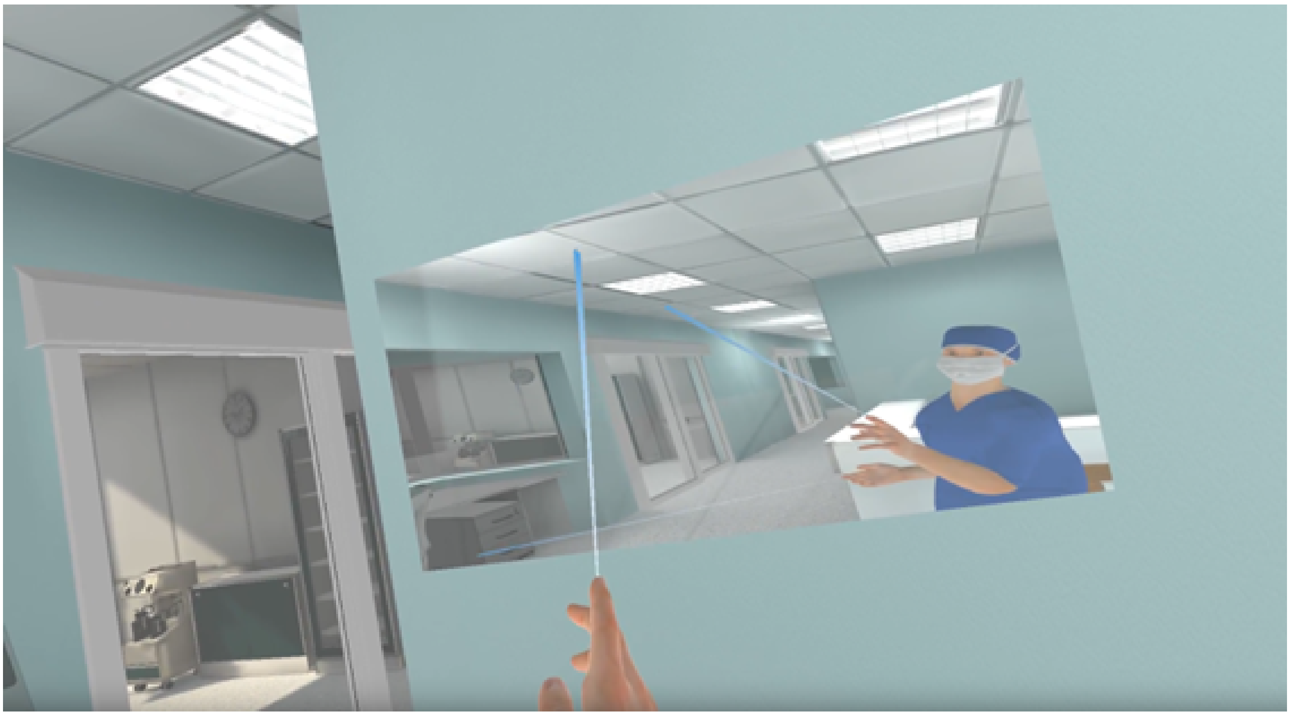
The PEARLS structure is a well-validated debriefing tool that is typically used to provide introspection on performance for a simulation participant [38]. It has been used extensively in the simulation literature, including a recent user qualitative study with patient-led simulations [39]. A PEARLS debrief integrates 4 main segments: setting the scene, eliciting reactions, description and analysis of the experience, and summary or reflections.

After the debrief, participants were asked to answer a debrief feasibility questionnaire with 3 five-point Likert questions answered on a scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*) about the relevance and utility of the psychoeducational content on MD for real-life situations as well as the ability of the VR scenario to elicit emotions (Multimedia Appendix 1).

User Experience

To assess the user experience within the VR scenario, we evaluated the dropout rate, the feasibility questionnaire, and the qualitative responses provided during the debrief. During the VR scenario, participants had their head and hand movements tracked by the VR headset and controllers, and all movements were mapped into a virtual avatar (Figure 4). To help improve the sense of body ownership (ie, making the users recognize the virtual body as their own) [40], the preintervention test started with a tutorial that had the participants looking at a mirror and moving their head and hands to visualize that their virtual avatar actions reflected their own.

Figure 4. Snapshot of the virtual reality scenario showing the participant’s avatar reflected in a mirror. The blue beam indicates the cursor used to interact with the virtual environment.



Ethics Approval

Ethics approval was obtained from the research ethics board at St. Michael’s Hospital before starting any study activities (21-066).

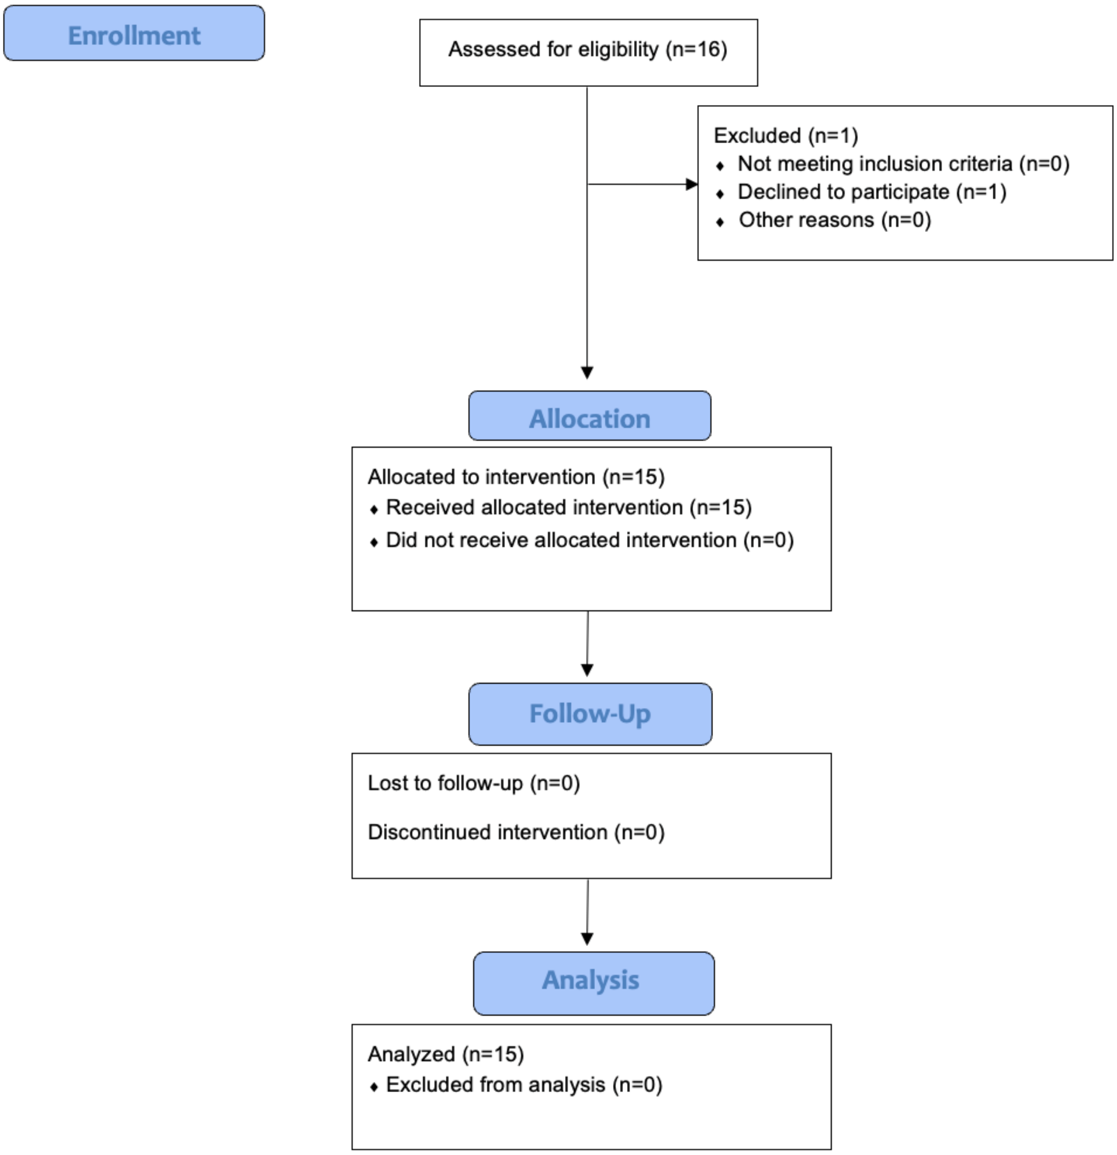
Results

Participants

Participant Flow

A total of 16 participants were assessed for eligibility; 1 (6%) declined to participate, and therefore 15 (94%) participants were allocated to the intervention. All 15 participants received the intervention. No participants were lost to follow-up, and data from all 15 participants were analyzed. Information on participant flow is presented in Figure 5.

Figure 5. Flowchart of participant enrollment and attrition.



Baseline Data

Our sample consisted of 15 HCWs (female participants: n=11, 73%; male participants: n=4, 27%). The participants had a mean age of 32.7 (SD 9.5) years; the male participants had a mean age of 34.3 (SD 4.9) years, whereas the female participants had a mean age of 32.2 (SD 10.9) years. Among the 15 participants, the most common occupations were nursing (n=7, 47%) and medicine (n=3, 20%); other professions included mental health research staff (n=2, 13%), physician assistant (n=1, 7%), educator (n=1, 7%), and graduate student (n=1, 7%). At the time of the experiment, none of the 15 participants had a prior or current COVID-19 infection; however, 4 (27%) had a prior family history of COVID-19 infection. The VR experiments were conducted between May 2021 and August 2021.

Data Analyzed

For 15 participants, MIOS, PSS, IPQ, and mobile data were analyzed. The data of 14 participants were analyzed for the content analysis.

Quantitative Analysis

Stress and MD Analysis

The average MIOS scores for the prebrief, preintervention test, postintervention test, and debrief were 10.4 (SD 9.9), 12.9 (SD 6.9), 12.6 (SD 7.1), and 13.5 (SD 9.1), respectively, with a difference between the debrief and prebrief (between after the intervention and before the intervention) of 3.1 (SD 6.8; Table 1). There was no statistical difference in the MIOS scores at the 5% level when comparing all 4 scores using the Friedman test (Q=4.61; *P*=.20). Using Bonferroni correction (.05/3=.0167), the results showed no significant difference between the prebrief scores and any follow-up score: preintervention test (*P*=.30), postintervention test (*P*=.32), and debrief (*P*=.11). The MIOS is a new scale that is still under development by the MIOS Consortium and has not yet been established for the assessment of MI [18,41].

Table 1. Wilcoxon signed rank test comparing Moral Injury Outcome Scale follow-up scores at preintervention test, postintervention test, and debrief with the prebrief score (n=15)[a].

	Values, mean (SD)	Values, median (IQR; range)	*P* value
Prebrief score	10.4 (9.9)	12 (0 to 17; 0 to 28)	N/A[b]
Preintervention test score	12.9 (6.9)	13 (6 to 17; 3 to 27)	.30[c]
Postintervention test score	12.6 (7.1)	13 (8 to 17; 1 to 28)	.32[c]
Debrief score	13.5 (9.1)	14 (5 to 18; 0 to 32)	.11[c]
Difference (debrief − prebrief)	3.1 (6.8)	1 (−1 to 7; −8 to 18)	.11[c]

[a]There was no statistical difference in the Moral Injury Outcome Scale scores at the 5% level when comparing all 4 scores using the Friedman test (Q=4.61; *P*=.20).

[b]N/A: not applicable.

[c]Follow-up scores were compared with the preintervention test score using the Wilcoxon signed rank test; Bonferroni correction was used (.05/3=.0167), that is, significance at 1.67% was applied.

PSS scores were only collected at 2 time points: at prebrief and debrief. The average PSS scores during the prebrief and the debrief were 17.3 (SD 7.5) and 19.1 (SD 8.1), respectively, with a postintervention test–preintervention test difference of 1.8 (SD 6.0; Table 2). Similar to the MIOS scores, the prebrief and debrief PSS scores were not statistically different (*P*=.22). Tables 1 and 2 summarize the analysis for the MIOS and PSS scores.

Table 2. Wilcoxon signed rank test of the Perceived Stress Scale prebrief and debrief scores (n=15).

	Values, mean (SD)	Values, median (IQR; range)	*P* value
Prebrief score	17.3 (7.5)	15 (12 to 22; 4 to 33)	N/A[a]
Debrief score	19.1 (8.1)	19 (14 to 26; 4 to 33)	N/A
Difference (debrief − prebrief)	1.8 (6.0)	1 (−1 to 7; −11 to 11)	.22[b]

[a]N/A: not applicable.

[b]Wilcoxon signed rank test to test no difference in the distribution between the preintervention test and postintervention test scores.

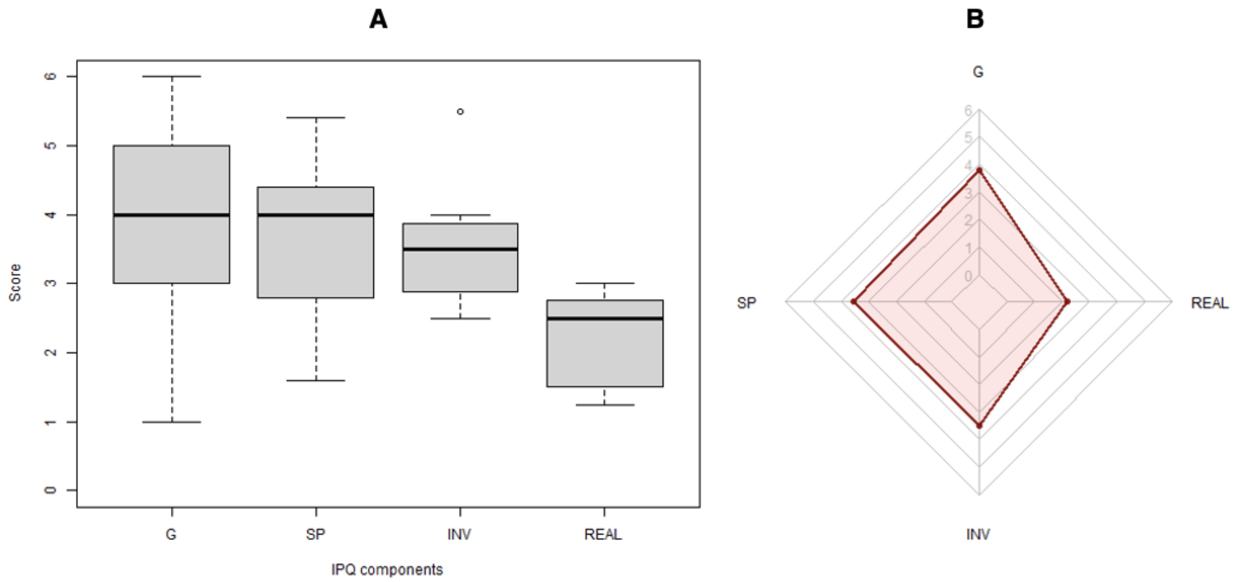
IPQ Assessment

On the basis of the data collected from the 15 participants, the VR scenario achieved an above-average degree of overall presence, spatial presence, and involvement, with slightly below-average realism (Table 3 and Figure 6). Considering that the presence component is influenced by the other 3 components, it makes sense that it has a higher variance and SD, which suggests an opportunity to improve the immersion of the VR scenario. The lowest scoring component was realism, with the lowest variance and SD. These findings are corroborated by the qualitative feedback provided during the debrief session, where only 5 (33%) of the 15 participants commented that the environment felt realistic and that they felt immersed in the experience. By contrast, 1 (7%) of the 15 participants stated that they found the environment more immersive than simulation with real people. The participants' feedback also highlighted other areas for future improvement, particularly regarding the realism component, such as having less restrictive dialogues, making the ICU environment more crowded, improving the voice-over acting features, and having the ICU equipment show patients' physiological data (eg, heart rate monitor).

Table 3. Igroup Presence Questionnaire data statistics.

	Values, mean (SD)	Values, median (IQR)	Variance
General presence	3.80 (1.47)	4.0 (2.0)	2.17
Spatial presence	3.53 (1.16)	4.0 (1.6)	1.34
Involvement	3.48 (0.78)	3.5 (1.0)	0.60
Experienced realism	2.20 (0.67)	2.5 (1.3)	0.45

Figure 6. (A) Box plot showing median, quartiles, extreme data points, and outlier. (B) Radar chart of the overall mean of the 4 Igroup Presence Questionnaire (IPQ) components. It uses a radial axis, with the center representing a score of 0 and the outer outline representing a score of 6. G: general presence; INV: involvement; REAL: experienced realism; SP: spatial presence.



Mobile Data Analysis

The dropout rates for the study app were very high. Of the 15 participants, 8 (53%) did not perform any survey, whereas 7 (47%) completed at least 1 questionnaire. Instead of answering surveys periodically, only 4 (27%) of the 15 participants had >1 set of survey results. There were not sufficient mobile data to provide informative analysis. In the future, an improved participant engagement strategy is needed to help optimize mobile data collection.

Post Hoc Sample Size Calculation

As an exploratory analysis, we calculated post hoc sample sizes using 2-tailed paired *t* tests with a significance level of .05 based on the mean differences in the MIOS and PSS scores observed between the respective scores at prebrief and debrief. The common SDs for each score were estimated using the observed larger SD among the 2 scores. The computed correlations between the 2 scores were used in this calculation. The sample sizes required to achieve a power of 80% were 41 and 95 participants based on the observed results for the MIOS and the PSS, respectively (Multimedia Appendix 2).

Qualitative Analysis

Content Analysis

Content analysis was performed for 14 (93%) of the 15 participants because technical issues compromised the speech recording of the 15th participant. Common references to real-life experiences were recognized in the content analysis, with the most frequent themes being the following: the virtual characters' choices during the experiment were too restrictive (10/14, 71%), feelings of some guilt or shame (8/14, 57%), no feelings of failure or being punished (7/14, 50%), no guilt or shame (6/14, 43%), need of organizational support to deal with the morally challenging situation presented in the experiment (7/14, 50%), numbness (5/14, 36%), and the VR scenario was immersive, real, or engaging (5/14, 36%). Of the 14 participants, 1 (7%; participant 13) provided contradictory responses to feelings of guilt and shame, once saying that they did experience these feelings and once saying that they did not. Furthermore, 2 (14%) of the 14 participants considered the learning experience about MD and MI valuable and useful to their daily practice. A complete summary of the content analysis is provided in Multimedia Appendix 3.

Participants also recommended some specific areas of improvement in the VR scenario; for example, the following suggestions were made by 1 (7%) of the 14 participants: the patient's vital signs were at a normal range although he was experiencing respiratory failure, the skin color should be consistent with that of the participant (all virtual characters were White), the scenario was unrealistic because other interventions apart from the ICU ventilator should have been portrayed, and photographs of the patient should have been added to better customize the character's appearance. Finally, 2 (14%) of the 14 participants reported not being able to relate to religious mentions of God in the VR scenario.

User Experience

Although only 3 (20%) of the 15 participants reported prior experience with VR headsets (Multimedia Appendix 4), there were no dropouts during the VR scenario (Figure 5). As we had expected that new VR users could potentially experience nausea or disorientation, participants were reminded multiple times during the prebrief that they could pause or stop the session at any moment. Having said that, of the 15 participants, 14 (93%) did not report any side effects; only 1 (7%) participant reported claustrophobia and slight anxiety at first, but these feelings quickly subsided, and the participant was able to complete the VR scenario without any further side effects or complaints. Finally, all participants agreed that the VR platform and scenario were easy to navigate (Multimedia Appendix 4). Regarding the debrief feasibility questionnaire, of the 15 participants, 6 (40%) agreed that they learned about MD and interventions, and 11 (73%) agreed that the knowledge about MD and interventions will help them perform better in real-life events (Multimedia Appendix 5). Although only 8 (53%) of the 15 participants agreed that the VR simulation managed to make them experience the same emotions as they would in a real-life event (Multimedia Appendix 5), during the qualitative debrief, common emotions cited included some guilt, shame, betrayal, and isolation, which are consistent with MD.

Discussion

Principal Findings

In this work, we developed a fully immersive VR scenario to emulate a real experience of a morally distressing situation by HCWs in a simulated ICU setting during the COVID-19 pandemic and assess its acute effects on physiological and psychological parameters as well as longer-term effects on MD. This was followed by an educational video on MD and MI and appropriate mitigation strategies for MD and finally a repetition of the VR scenario in a pretest-posttest design. Because of COVID-19 constraints that resulted in health care settings often being described as a *war zone* [42], HCWs have been particularly exposed to PMIEs in their work environment during this pandemic [4,7]. However, despite the attention it has gained over the last decade, the concept of MI remains poorly understood. VR is a promising strategy to investigate MI owing to its ability to provide highly controlled virtual environments, personalized and tailored experiences, and full control and monitoring of the participants by the research team. The VR scenario created by the research team involved a complex ethical problem that became unfortunately frequent owing to the strain of the pandemic: prioritizing which patients would receive vital support in the face of the shortage of essential equipment such as ventilators [6]. This situation may be considered morally distressing because participants may witness the transgression of some of their core moral values [12], but it is not considered severe enough to induce MI. To achieve our goals, we performed a thorough quantitative and qualitative analysis of the acceptability, easiness of use, tolerability, and utility of the VR technology using a head-mounted display. To the best of our knowledge, this study is the first to examine the feasibility of using an immersive VR scenario to investigate the psychobiological impacts of a moral stressor on HCWs, as well as to use physiological parameters to predict the severity of stress and symptoms of MD and MI.

The feasibility analysis showed high acceptability of the VR scenario among participants, with no dropouts occurring during the study. Although only one-fifth of the participants (3/15, 20%) had previously used VR, all participants reported that the VR technology was easy to use. Moreover, the tolerability was also high because only 1 (7%) of the 15 participants reported mild transient side effects (claustrophobia); no participants reported nausea, whereas other specific side effects (eg, headache and dizziness) were neither reported by participants nor inquired on by the research team. This finding aligns with the literature showing that the incidence rate of VR-induced side effects is low and ranges between 0.5% and 8% [43], with the most common side effects being nausea, eye strain, and dizziness [43]. Specifically, nausea is reported to have an incidence rate of 5.2% [44], whereas vomiting is considered a rare event with an incidence rate of approximately 2% [45]. These symptoms are defined as cybersickness, a form of motion sickness that may be experienced during immersive VR experiences [44]. In this study, we hypothesize that the lack of nausea and other symptoms of cybersickness may have been due to limited head motion during the VR scenario and to the relatively reduced duration (mean 26.3, SD 2.7, min) of the experiment [46].

Regarding the technical quality of our VR scenario, the IPQ results revealed that the scenario achieved a high degree of general presence and spatial presence, above-average involvement, and slightly below-average realism. Therefore, most of the participants felt immersed and involved in the virtual environment but reported that the experiment was not realistic enough (10/15, 67%). This lack of realism was corroborated by the content analysis, where only approximately one-third of the participants (5/14, 36%) felt that the scenario was immersive, real, or engaging. To improve the experience of realism in virtual hospital environments, future studies could address the limitations pointed out by participants in the qualitative debrief session, such as more realistic ICU settings with equipment displaying patients' vital parameters and having ethnically diverse virtual characters to be more representative virtual avatars of participants.

Content analysis of the debriefing revealed that feelings of guilt, shame, betrayal, isolation, and failure were commonly reported; these are impairing moral emotions consistent with MD [7,17,47] and might suggest a violation of moral beliefs. This finding suggests that the VR scenario could acutely induce real experiences of mild MD. Interestingly, numbness was mentioned by approximately a third of the participants (5/14, 36%). This feeling could be considered as a consequence of not having real power in relation to a real-world experience; it may also represent an emotional consequence of being exposed to a PMIE [12,18]. We assume that numbness could be related to potential signs of the erosion of moral agency, not in relation to our intervention but to previous real-world experiences of prolonged and repeated stressors and moral stressors. The content analysis revealed that most of the participants (8/14, 57%) reported guilt and shame, which are feelings consistently related to the experience of MD [7,17]. This finding suggests that the moral stressor experienced during the VR scenario could successfully induce some degree of MD. In addition, half of the participants (7/14, 50%) expressed the need for organizational support, an aspect frequently related to MD. Participants suggested that there could be a greater emphasis on organizational dimensions in future simulations, given the expressed need and the alignment with past research on MD [48]. The findings from the content analysis supported our hypothesis that a VR scenario can be successfully used to elicit and discuss real-life experiences and emotions related to MD.

In contrast to the qualitative results, the quantitative analysis did not show significant changes in the MIOS scores between before and after the experiment. The PSS scores showed the same trend and were not significantly different from baseline, which contradicts our hypothesis that the VR scenario would significantly increase stress levels. Both the MIOS and the PSS focus on symptoms developed over the last month. Although participants were instructed to rate their symptoms at that specific moment, these scales might not have enough sensitivity to capture acute changes in stress and MD symptoms. Alternatively, the changes in MD symptoms may have not been severe enough to induce significant changes in the MIOS scores acutely. Combining our findings from the qualitative and quantitative analyses, we assumed that some degree of MD was experienced by most participants, but we believe that these symptoms were not severe enough to induce MI. This is an important ethical aspect because the VR scenario was designed by specialists in MD and MI to minimize the risk of inducing significant MD in participants.

As MI may develop in the long term, we additionally attempted to use a mobile app to monitor participants for stress and MD and offer psychological support during an 8-week follow-up. Unfortunately, a longitudinal analysis of MD during the follow-up was not possible owing to very low app compliance. It is possible that participants might have developed additional symptoms of MD during follow-up that otherwise could not be captured by our analysis. However, we believe that this is unlikely because no participants requested the psychological support offered in the study. Alternatively, the brief version of the MIOS might not have been sensitive enough to detect slight but important changes in MD that would otherwise be detected by its complete version or by another MD scale. Having said that, this study is a feasibility study with a small sample size, and such an implication is beyond the scope of this work. Finally, the MIOS is still under development; hence, future studies are needed to assess the validity of the MIOS and its brief version.

Mobile app retention proved to be challenging because more than half of the participants (8/15, 53%) did not use the study app, and less than one-third (4/15, 27%) completed at least 1 set of surveys. Our app engagement strategy was based solely on in-app automated reminders and was insufficient to promote participant retention. This finding is supported by recent literature that recommends a combination of different engagement strategies to optimize app use [49,50]. In addition, another possible explanation for the low compliance is that a user-centered design process was not adopted during app development; therefore, the study app may not be particularly targeted to HCWs as the end users [51,52]. Nevertheless, our results are in line with previous research that demonstrates that retention is frequently a great challenge in mobile health studies in both clinical and nonclinical samples [50,53].

Post hoc sample size calculations indicate that a 3-fold and 6-fold sample size is required to reach a power of 80% for the MIOS and the PSS, respectively. With a sample of only 15 participants, our results were underpowered, which may at least in theory explain the nonsignificance of our quantitative findings and the discrepancy between the qualitative and quantitative results. This study was developed during a critical period of the COVID-19 pandemic, with recruitment occurring between May 2021 and August 2021, when contact restrictions were very strict. As the VR intervention required in-person data collection, recruitment proved to be very challenging. Nevertheless, our sample size of 15 participants is appropriate for a preliminary analysis, considering previous VR studies published in PTSD and other mental health disorders [54-57]. Our post hoc sample size calculations may be useful to guide the design of future adequately powered studies using VR in the context of MD and MI.

Limitations

This study has several limitations that must be considered. First, it is a pilot feasibility study with a single arm and a small sample size; thus, the results should be interpreted with due caution. Additional studies with a controlled design are necessary to assess the safety and effectiveness of VR interventions in the assessment of MD and MI. Second, stratification analysis by demographic variables was not possible owing to the reduced sample size; therefore, we were unable to compare symptoms of MI among different subpopulations (eg, nurses and physicians). In addition, our experiments were performed on a purposive sample of only HCWs, thus limiting the generalizability of our findings to other populations. Third, the debriefing methodology used may have also provided a different lens than a traditional qualitative interview or focus group. Fourth, the MIOS and the PSS were used outside of their time frame scope; additional studies should include assessments that focus on acute symptoms of stress and MD. Fifth, a standardized cybersickness scale to assess the side effects within the VR scenario, such as the Virtual Reality Sickness Questionnaire [58], was not used and might have caused underreporting of side effects in this study. Sixth and last, the low app engagement found during the 8-week follow-up hindered an analysis of any potential long-term consequences of the experiment related to MD. Considering that the symptoms of MI may have a late onset, this represents an important limitation to our findings.

Conclusions

The COVID-19 pandemic has challenged the mental health of HCWs, with increased rates of distress, anxiety, and depression being reported. During patient care, ethically difficult situations became common and put frontline HCWs at risk of MD and MI. VR-based interventions are a promising method to address these limitations because they allow for the possibility of developing experiments in safe, personalized, and highly controlled environments. This pilot study investigated the feasibility of using a VR scenario to simulate the experience of a mild morally challenging event for HCWs during the COVID-19 pandemic and to examine participants' physiological reactions to making morally difficult decisions in a virtual environment. Our results suggest the feasibility of using a VR scenario to simulate real experiences of morally stressful events and elicit genuine responses associated with MD with high acceptability and tolerability. In addition, our VR-based intervention demonstrated utility as a pedagogical tool for teaching possible ways to prevent and mitigate MD. Future studies should be conducted to further validate our findings in a larger sample.

Acknowledgments

This work was funded by Innovation for Defence Excellence and Security (IDEaS), Competitive Projects, Department of National Defence, Canada. The authors are grateful to Dr Deborah Kenny, Ms Kristen Sampson, and the Unity Health Toronto Simulation Program for their contribution and support. The financial support of the Ontario Trillium Scholarship program is gratefully acknowledged by AT.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

The study was conceptualized by VB along with SK, EP, and AD. CWE was involved in the interpretation of results, manuscript write-up, and revision. BN and AT were involved in software design of the virtual reality scenario, data collection, data analysis, and the writing of methods and quantitative results. WS was involved in data collection and logistics. AR performed quantitative data analysis. EP was involved in scenario development and qualitative data analysis. LB and DMC provided support with logistics and the debrief component. HJ conducted statistical analysis under the supervision of WL. BK and AD supervised AT for the creation of the virtual reality scenario. SK and VB supervised CWE, BN, and AT on all their tasks.

Conflicts of Interest

VB is supported by an Academic Scholar Award from the Department of Psychiatry, University of Toronto, and has received research support from the Canadian Institutes of Health Research, the Brain & Behavior Research Foundation, Ministry of Health Innovation Funds, the Royal College of Physicians and Surgeons of Canada, the Department of Defence (Canada), and an investigator-initiated trial from Roche Canada. All other authors declare no other conflicts of interest.

Abstract

Background: Rhythm perception and production are related to phonological awareness and reading performance, and rhythmic deficits have been reported in dyslexia. In addition, rhythm-based interventions can improve cognitive function, and there is consistent evidence suggesting that they are an efficient tool for training reading skills in dyslexia.

Objective: This paper describes a rhythmic training protocol for children with dyslexia provided through a serious game (SG) called Mila-Learn and the methodology used to test its usability.

Methods: We computed Mila-Learn, an SG that makes training remotely accessible and consistently reproducible and follows an educative agenda using Unity (Unity Technologies). The SG's development was informed by 2 studies conducted during the French COVID-19 lockdowns. Study 1 was a feasibility study evaluating the autonomous use of Mila-Learn with 2500 children with reading deficits. Data were analyzed from a subsample of 525 children who spontaneously played at least 15 (median 42) games. Study 2, following the same real-life setting as study 1, evaluated the usability of an enhanced version of Mila-Learn over 6 months in a sample of 3337 children. The analysis was carried out in 98 children with available diagnoses.

Results: Benefiting from study 1 feedback, we improved Mila-Learn to enhance motivation and learning by adding specific features, including customization, storylines, humor, and increasing difficulty. Linear mixed models showed that performance improved over time. The scores were better for older children ($P<.001$), children with attention-deficit/hyperactivity disorder ($P<.001$), and children with dyslexia ($P<.001$). Performance improved significantly faster in children with attention-deficit/hyperactivity disorder ($\beta=.06$; $t_{3754}=3.91$; $P<.001$) and slower in children with dyslexia ($\beta=-.06$; $t_{3816}=-5.08$; $P<.001$).

Conclusions: Given these encouraging results, future work will focus on the clinical evaluation of Mila-Learn through a large double-blind randomized controlled trial comparing Mila-Learn and a placebo game.

Introduction

Background

Music training and music-based interventions are becoming increasingly popular for developing brain and cognitive functions in children [1-5]. Building on brain plasticity induced by learning music and the tight link between musical and cognitive skills [6-8], music interventions have been used as training tools in neurodevelopmental disorders (NDDs) such as dyslexia [9-13]. Musical skills, especially when developed in childhood, are associated with enhanced cognitive abilities in various domains, such as attention, processing speed [3], executive functions [14], or speech and language [15-17]. Improvements in cognitive skills induced by musical training have been attributed to structural and functional brain changes in areas that support both music processing and cognition [6-8,18,19].

Recent studies have focused specifically on the relationship between rhythmic skills, such as the capacity to discriminate musical rhythms or synchronize with a beat [20,21], and cognition during development. Tierney and Kraus [22] showed that correlations exist between synchronization with a metronome and attentional and reading skills in typically developing adolescents. In children, rhythm production accuracy is associated with both phonological awareness and reading [23]. Rhythm perception is also related to reading performance [24,25]. Language and music processing may rely on common timing mechanisms that allow for the extraction of temporal information, which is crucial to accurately perceive sequences of events [7,20,26-28]. This hypothesis is supported by neurofunctional evidence as temporal processing involved in music and language recruits partially overlapping neuronal pathways that include the auditory cortex, dorsal premotor cortex, cerebellum, basal ganglia, and thalamus [29,30].

Further evidence of the link between rhythmic skills and cognitive abilities comes from the observation that rhythmic skills are disrupted in NDDs that also affect cognition. Notably, rhythmic deficits have been extensively reported in individuals with dyslexia. Children and adults with dyslexia exhibit inaccurate rhythm perception [25,31] as well as increased variability in motor tapping tasks [32]. These observed rhythmic deficits have given rise to theories (eg, the temporal sampling framework; Goswami [26]) that postulate that poor predictive temporal sampling and coding of events explain reading difficulties in those with dyslexia [26,33].

Building on the importance of rhythmic skills in development, music-based training protocols for children have been developed in recent decades. Studies have shown that children with dyslexia who participate in music-based interventions display better reading and phonological abilities [10-12]. In addition, the effect of music-based programs was extended to typically developing children, who showed significant improvements in speech processing skills and verbal intelligence [14]. However, these encouraging preliminary data have not reached the recommended quality for evidence-based studies owing to methodological limitations such as limited sample size, lack of blind assessment, and potentially inconsistent delivery of interventions [34]. In addition, access to these interventions is still too limited, with inequalities remaining because of significant disparities according to social background and place of residence [35]. For instance, children in poor and remote urban areas, who are more likely to develop an NDD [36], often have less access to care. Furthermore, these traditional music-based interventions usually require in-person instruction, which can be challenging under certain circumstances such as during the COVID-19 pandemic or in areas with limited access to specialized resources. More research is needed to determine whether written language skills can improve in children with dyslexia after training with more accessible and scalable music-based interventions.

To address these limitations, serious games (SGs) designed for educational and training purposes provide a more standardized, scalable, and accessible format for delivering music-based interventions through information and communications technologies. This approach allows for the delivery of the same training to a large sample regardless of geographic location or in-person resource availability. The number of SGs developed for educational and training purposes has increased over the last decade [37], primarily because of the expansion of information and communications technologies such as mobile technologies and telehealth systems. As most households, including those in low-income brackets and rural areas, are now equipped with at least 1 tablet, smartphone, or computer, these SGs can be broadly accessible [35]. Furthermore, a meta-analysis revealed that, across domains, learning is improved with SGs compared with conventional methods [38]. In addition to motivation, several preliminary findings have supported another exciting alternative hypothesis that playing an SG fosters electrical brain activity related to memory, emotions, and concentration [39], providing a possible neuronal explanation for the beneficial effect of SGs. SGs have been used in typically developing populations [40] and in children with NDDs [41,42]. Notably, SGs have been used to deliver rhythm-based training to healthy young adults [43]. Recently, interest in using computer-based interventions to train rhythm skills has been explored in people with dyslexia [44]. One SG named “Jellys” was developed for this purpose in a usability study and showed that children with dyslexia positively engaged with this type of remediation [45]. However, although some studies seem to support the effectiveness of using SGs as a treatment for people with NDDs, the methodological quality of these studies is limited, and further research is needed [46].

Objectives

In this study, our goal was to evaluate the usability of Mila-Learn, an SG aimed at training rhythmic abilities in children with dyslexia. The methodological design of the game was developed in user participatory pilot studies, allowing the children and their families to provide feedback to shape human-machine interactions. We report on 2 studies conducted during the French COVID-19 lockdowns. The first was a feasibility study to assess the children’s engagement through gameplay frequency and collected their feedback. After modifying the SG according to the feedback by adding specific features such as customization, storyline, humor, or increasing difficulty, we report a usability study that addressed the children's performance on the latest version of the SG when played autonomously at home and according to declared diagnoses.

Methods

Overview

Mila-Learn is an SG that delivers rhythm-based exercise designed for children with dyslexia (called "specific learning disorders in the field of reading" in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*). This SG involves a rich musical universe aiming to lead the child to spontaneously come back and engage with the instrument with their parents. It consists of two main elements: (1) a mobile app that offers rhythmic, sensory-motor, and cognitive tasks in the form of musical activities; and (2) secure servers that allow for data analysis. It enables real-time evaluations to understand children's difficulties and improve the effectiveness of Mila-Learn. In this section, we first describe the SG from its initial beta version. We then detail the methodology of the 2 exploratory studies conducted during the COVID-19 lockdown.

Mila-Learn Description

From an Initial Prototype (2018) as a Progressive Web Application to a Version (2019-2020) Developed for Tablets

The first version of Mila-Learn included five tasks:

1. Dance With Your Hands is an auditory-motor coordination exercise. It involves performing a movement following the tempo of a piece of music. These are pieces with a 4/4 signature that easily allow the child to have rhythmic stability and associate a motor action with the rhythm. This action includes gestures such as clapping, silencing, and raising the arms in the air.
2. Play the Drums is a rhythmic memory game. A drum appears on the child's screen, and a sequence is played. The child then presses on the drum elements to reproduce the initially played sequence.
3. Rhythmic Vitamins is an exercise in singing and repetition [47]. An initial recorded vocal sequence consisting of syllables and phonemes is played by the software. The child must reproduce it using the rhythm, pronunciation, and pitch of the initial sequence.
4. Following the Tempo requires recognizing and reproducing different rhythmic structures. In this exercise, the child is asked to mark the strong beats of music using the space key on the keyboard.
5. Musical Pitch is an exercise of association between the pitch and its representation. A sound sequence composed of 3 sounds is played (high, medium, and low), and then a visual representation is displayed composed of lines (low, medium, and high). The child has to judge whether the graphic production of the sound is correct.

This prototype version (Figure 1 [48]) was offered to a small group of children end users with dyslexia. We asked them to provide feedback on the design and players. The data collection method was centered on gathering children's feedback at the end of 15-minute game sessions. A total of 14 children were invited to respond, interact, and provide feedback on the first version of Mila-Learn in the form of a progressive web application [49]. In total, 3 sessions per week over a period of 3 months were conducted.

Figure 1. Landing page of the prototype with 3 different tasks each day [56].

This participatory design phase led to a framework for the development of Mila-Learn enhanced by a literature review on SG playability to increase players' motivation. Although some studies have proposed a framework to develop SGs for people with NDDs, very few have focused specifically on dyslexia [46]. To improve the design of our game, we expanded our research to the use of SGs in the typical population and in children with NDDs, especially children with attention-deficit/hyperactivity disorder (ADHD), because of the high co-occurrence between dyslexia and ADHD [50].

Design Framework

We integrated new gaming features to increase players' motivation and engagement. First, we developed a storyline that allowed us to include the different tasks within a larger story. The use of a storyline supported the engagement of a player in the games [51,52]. The storyline was intended to not be complex to prevent the child from losing the main goal of the game [53]. The story in Mila-Learn was designed to correspond to the interests of children aged between 7 and 14 years. The story is inspired by *shonen* manga, which is manga inspired by the cartoon universe. This type of manga is based on a storyline that involves a young hero who starts without knowledge and becomes increasingly powerful during the progression of the story. Some crucial values such as friendship and perseverance are typically present in the story. Most of the time, the first opponent of the hero becomes his friend during the story. In Mila-Learn, the player embodies a little monster who meets another character, a little blue monster named "Blue" who asks for their help—some villagers are held captive by the villain Diabolus, another character. The player has to learn rhythm skills to challenge Diabolus and free the villagers. Over the course of the game, the player discovers that there is a larger villain who holds "Rosa," the Diabolus' scooter. At the end, the player must win a large rhythm tournament to finish the game. The story is divided into 12 chapters containing 6 tasks (see the following section). Each task lasts between 1 minute, 20 seconds and 1 minute, 30 seconds, with rare songs playing for 1 minute, 40 seconds to maintain consistency with the music. In this way, we considered the attention capacity of children [53,54].

As recommended in the literature, we created evolving tasks, gradually increasing the level of difficulty in each task and from one task to another [51,53,54]. The tasks must be challenging but accessible. In total, 6 tasks are used in the second version of Mila-Learn. They are introduced progressively to allow the player to practice a task 2 to 3 times before introducing another one. Once all the tasks are known by the player, they increase in difficulty with progression throughout the game. First, within each task, the rhythm displayed corresponds to each beat of a measure. Then, the rhythm changes to correspond to eighth notes (meaning that the rhythm is clapping 3 times in 2 beats) or slows down to be marked only once every 2 beats. Moreover, the songs are played at an increased speed to challenge the player. At higher levels, the marked rhythms can change during the task.

The SG was built to provide clear instructions to the player [51,53]. The instructions are given orally and with visual support, notably by imitating one or more nonplayer characters. Before each task, a quick tutorial allows the player to repeat the movement they have to perform during the game 3 times (ie, clap their hands, touch the screen, and move the tablet). At the beginning of a task, the character played by the user is clearly identified with an arrow. Moreover, for each task, the player is always placed in the same location.

The visual environment is thought to be easily navigated by children. The graphics are pleasant but minimalistic [53,55]. The visuals are thought to be pleasant for children aged between 7 and 14 years and are inspired by the cartoon universe. During the tasks, the background is mostly static, allowing the child to focus on the goal of the task. The characters only move to the rhythm of the music, with repetitive and predictable movements.

We differentiate between short- and long-term goals [51,53,54]. In each task, there is only 1 clear goal (ie, touch the screen to the rhythm) that is clearly differentiated from the long-term goal of a chapter (ie, complete the chapter to challenge Diabolus; Figure 2). Feedback is provided throughout the different tasks using visual cues [51,53,54]. These cues allow the player to know whether they are performing the exercise properly. The feedback for each task is described in the following section. As rewards have been described as a main feature of SGs [51,54], players obtain a reward of 1 to 3 stars at the end of each task depending on their accuracy during the exercise. Personalization has also been described as an important key to enhancing the motivation of the player [51-54]. As in the first version, players have to pick a name for their character at the beginning of the game and modify its color. Finally, we introduced new songs to work on in this version of the game. We added some famous songs known by most children (ie, songs from Disney movies) to increase the motivation of the players. For some tasks such as Fruity Jump, Karate Fruit, and Sing Lab, the predetermined structures of these songs did not make their use possible. We specifically composed songs to fit with the requirements of these tasks.

Figure 2. Example of a chapter menu introducing the upcoming adventure.

Description of the Tasks

All the tasks (Figure 3) were designed to work on rhythm, which was the main and explicit goal of each task. However, each task requires the mobilization of other skills such as attention, inhibition, working memory, and motor skills, which are also often impaired in children with dyslexia [50,56].

Follow me aims to introduce rhythm to the player. The child first sees a little monster clapping hands to the rhythm of a song and then has to touch the screen to the rhythm by imitating the monster. Then, the character stops clapping, and the player has to keep going alone without the support of the monster. This task allows the player to work on maintaining regularity in rhythm but also sustained attention.

In Clap Trap, 2 characters and the player appear on the screen. The first 2 characters clap one after another, giving a tempo to the player, who has to complete the sequence by clapping their hands to the rhythm at the right time. The first character claps on the first beat of a 4-time measure of the song played. The second character claps on the second beat, and the player has to clap their hands on the third beat. The microphone records the child’s clap. In this task, the child has to anticipate and adapt to the rhythm. It was designed to train inhibition skills as the child has to wait until the right moment to clap their hands.

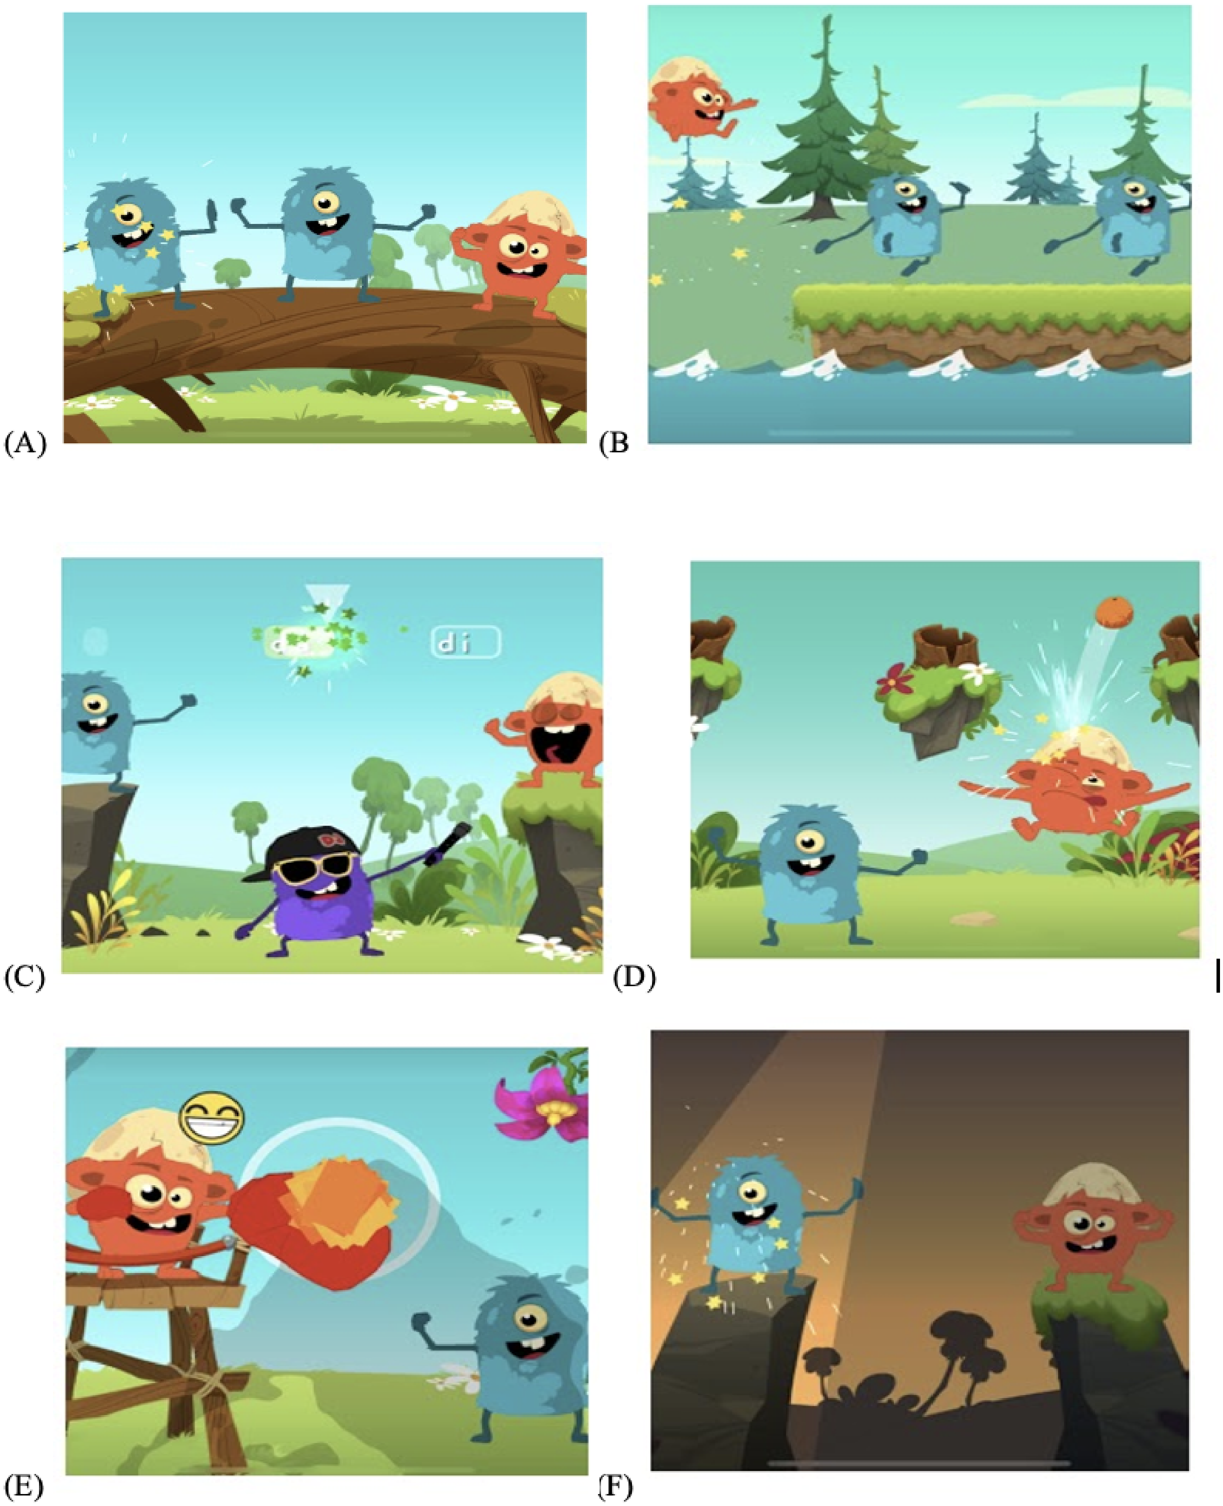
In River Splash, the player is placed behind 2 other characters who run next to the water and sometimes have to jump across the river to the rhythm. The first character jumps on the first beat of a 4-time measure of a song. The second character jumps on the second beat, and the player jumps on the third beat. The player has to shake the tablet quickly to jump. In addition to rhythm perception, this task was designed to train inhibition skills similarly to the Clap Trap task.

In Sing Lab, the first character produces a sequence of phonemes or syllables at a particular tempo. The player has to reproduce this sequence with particular attention to the pattern and duration of the phonemes. Phonemes or syllables pass across the top of the screen, visually represented by gauges that the player has to fill. If the child sings at the right time, the gauge starts filling. When the duration of the note is complete, the gauge changes color from white to green. In this task, the phonological loop is involved in correctly memorizing the sequence. We used specific music constructed for this task that allowed us to add phonemes or syllables to sing at particular moments and for as long as we wanted.

In Fruity Jump, a character reproduces a rhythmic sequence. The player has to memorize this sequence and then reproduce it correctly by tapping the screen at a good tempo. The tempo is visually indicated by fruits falling from a tree. If the player claps at the right time, the character jumps and hits a fruit with its head to throw it to another tree. If the player misses the fruit, it crashes on the ground. If the player jumps at another time (ie, during the demonstration), their character jumps, and nothing special happens. Working memory and intermodality are particularly engaged in this task.

Finally, in Karate Fruits, the player has to hit fruits that appear based on the rhythm. To hit the fruit, the player has to put the tablet on the floor and extend their arms above it. Each time the camera detects the arm, the player’s character punches. If the player punches at the right time, the fruit explodes, and a smiley face appears. If the player misses the fruit, the fruit goes off the screen, and a smiley face with an annoyed head appears. If the player punches at another time, the character punches, and nothing else happens.

Figure 3. Examples of screens in Mila-Learn: (A) Clap Trap, (B) River Splash, (C) Sing Lab, (D) Fruity Jumps, (E) Karate Fruits, and (F) Follow Me.



Scoring Player Performance

Scoring of player performance is based on rhythmic synchronization through multiple modalities of interaction (sometimes in combination) as rhythmic synchronization is a requirement for all games. Player responses are captured through accelerometers, microphones, webcams, and pressure-sensitive screens, as shown in Table 1.

By assessing the audiomotor synchronization of the child with the rhythmic instruction, we define (1) a time T that corresponds to the exact moment when the player's input is expected (regardless of the interaction mode) and (2) tolerance thresholds ($t_{Perfect}<t_{Good}<t_{Correct}$).

The different intervals allow for judging the quality of the answer with 4 levels of acceptance. An input is considered acceptable when it is in the interval [$T - t_{Correct}$; $T + t_{Correct}$] and not acceptable otherwise. An input of better quality, either in the interval [T – t_{Good}; T + t_{Good}] or in the interval [T – $t_{Perfect}$; T + $t_{Perfect}$], results in different visual and audio feedback for the child.

In the second improved version, which was a modified version based on the first pilot study, a simplified calculation was performed by considering the ratio of acceptable inputs to total inputs as the main measure. This final score is presented to the child in the form of stars depending on their performance: no stars if the child has an average of <50%, 1 star if ≥50% of inputs are acceptable, 2 stars for ≥75%, and 3 stars for ≥90%. In addition, this architecture allows for the storage of all the child's inputs for retro-analysis purposes.

Table 1. Players' recorded responses and game parameters in the second version of Mila-Learn.

Task	Type	Interaction	Capture technology	Songs	Tolerance threshold
Follow Me[a]	Continuous tapping	Tapping	Contact pressure	Commercial	• $t_{Perfect}$: 0.1 s before or after the beat • t_{Good}: 0.15 s before or after the beat • $t_{Correct}$: 0.25 s before or after the beat
Clap Trap	Last beat	Clapping hands	Microphone	Commercial	• $t_{Perfect}$: 0.1 s before or after the beat • t_{Good}: 0.15 s before or after the beat • $t_{Correct}$: 0.25 s before or after the beat
River Splash	Last beat	Shaking tablet	Accelerometer	Commercial	• $t_{Perfect}$: 0.1 s before or after the beat • t_{Good}: 0.15 s before or after the beat • $t_{Correct}$: 0.25 s before or after the beat
Sing Lab	Call and response	Singing	Microphone	Commercial+built in-house	• $t_{Pattern}$: 0.15 s before or after the beat and up to 30% of the note duration • Song duration: the note must be sung at least 60% of the time
Fruity Jump	Call and response	Tapping	Contact pressure	Built in-house	• $t_{Perfect}$: 0.2 s before or after the beat • t_{Good}: 0.25 s before or after the beat • $t_{Correct}$: 0.3 s before or after the beat
Karate Fruits	Last beat	Punching	Webcam	Built in-house	• $t_{Perfect}$: 0.08 s before or after the beat • t_{Good}: 0.14 s before or after the beat • $t_{Correct}$: 0.3 s before or after the beat

[a]Name of the task.

Feasibility Study

We conducted a feasibility study to evaluate whether children with NDDs involving reading deficits could use Mila-Learn autonomously at home. Our main objective in assessing Mila-Learn's autonomous use was to monitor both the time users spent on the SG and their accuracy in each game played. In the context of the unprecedented health crisis caused by COVID-19, participants were recruited by the French Federation for Learning Disorders (FFDys), a national association that aggregates all regional associations of people with learning disabilities. The FFDys communicated to its members the possibility of testing an app and managed the information and consent of participants. Families were informed that Mila-Learn was an SG for performing rhythmic tasks at home and that we believed this practice might be beneficial for learning to read. In total, 2500 children downloaded Mila-Learn. The analyses were conducted on a subsample of 21% (525/2500) of these children, who spontaneously played at least 15 games. To improve the usability of Mila-Learn, we also asked users (both children and families) to provide feedback on the games and information on the children's impairments. This information was provided freely and was not compulsory to obtain Mila-Learn. In addition, we systematically collected through phone interviews all the problems that the children and their families encountered regarding the computing and web performance of the SG. Finally, we conducted a phone survey of 200 users, which is provided in Multimedia Appendix 1 [56]. The questions asked were designed to gain insights into the families' perceptions of the benefits of the tool, the improvements and difficulties of use they encountered, and their desire to continue using the game in the future; in addition, room was left for unstructured testimony. The data analysis for the feasibility study was limited to descriptive statistics.

Usability Study

This usability study was considered a continuation of study 1 and was conducted under the same ethical rules. In the usability study carried out in a real-life setting over 6 months, our primary focus was 2-fold following modifications to Mila-Learn based on study 1 feedback: first, to ensure that the computational architecture and final version of Mila-Learn were free of computer bugs and, second, to track player progress using Mila-Learn's scoring system over an extended duration. As part of the second lockdown because of the COVID-19 crisis, the final version of Mila-Learn was made available again starting on October 10, 2020, on National Learning Disabilities Day. Benefiting from the large amount of feedback received during the first lockdown, very few technical problems occurred, resulting in a game with much better fluidity that provided higher-quality data. A total of 3337 children had access to Mila-Learn for a total of 84,682 games that were played. As in study 1, at the time of registration, the patients' families were given the opportunity to complete the profile of the children, including information such as the children's diagnoses. A total of 304 diagnoses were reported by the parents. Finally, the children and their families had the option of linking the game character to the reported clinical profile. This option was exercised by 2.94% (98/3337) of the children, for whom we had both their reported diagnosis and game performance over time. These 2.94% (98/3337) of the children completed 3922 games.

To assess how children performed with Mila-Learn, we defined and computed the following variables:

1. "Time" is an incremental value representing the number of levels played by a player since the beginning of the experiment. Time is 1 at the beginning of the experiment and represents the total number of levels played by the player at the end of the experiment.
2. "Delta_tap" is the delay between the date of the played input (as defined in Table 1) and the date of the expected input.
3. "Threshold" is a delay defined for each game that was used to construct the performance score.
4. "Performance score" is a variable bounded between 0 and 100 that was created to quantify performance from delta_tap and normalize performance across games. We used the following formulas: performance score = (–100/threshold) × abs(delta_tap) + 100 for abs(delta_tap)≤threshold and performance score=0 for abs(delta_tap)>threshold.

We conducted several linear mixed models. To assess children's progress over time, we tested whether players improved their performance through the progression across the games using a linear mixed model with the following formula: performance score ~ time + (1|PlayerID/GameID/LevelName).

To assess whether a declared diagnosis was associated with the average performance of the children, we also conducted a linear mixed model using the following formula: performance score ~ age + dyscalculia + dysgraphia + dyslexia + dysphasia + ADHD + ExecutiveFunction impairment + (1|GameID/LevelName).

Finally, we also tested whether progress over time was moderated by a declared diagnosis using the following formula: performance score ~ time + diagnosis + time × diagnosis + (1|GameID/LevelName).

Ethical Considerations

Under French legislation, we did not need the approval of a Comité de Protection des Personnes (Committee for the Protection of Persons). However, as the pilot study was conducted in line with the creation of large databases, we obtained the approval of the Commission Nationale de l'Informatique et des Libertés (National Commission for Informatics and Freedoms) under number 2222283.

Results

Feasibility Study

Between April 2020 and June 2020, a total of 2500 children had access to Mila-Learn. Families reported the child's diagnosis in 60% (1500/2500) of cases. As children were recruited through the FFDys, they were diagnosed with an NDD in almost all cases, but only 23% (575/2500) were declared as having dyslexia. The other children had developmental coordination disorders (dyspraxia), dyscalculia, and communication disorders of oral language (dysphasia). In addition, 18% (450/2500) declared a diagnosis of ADHD.

Data regarding the use of Mila-Learn by each user were recorded as time spent on the SG and accuracy in each game played. The average use was 3.5 sessions per week. To ensure the significance of the data, we only kept the data of players who participated over a sufficient period (>15 games). Duration was expressed as the number of games played. We considered the number of games played inside the SG over the number of played sessions as the number of games played in 1 session could vary widely. In total, 21% (525/2500) of players aged 6 to 14 years played at least 15 games, with an overall mean of 54.77 and a median of 42 games played. The average number of games played was similar across ages (no main effect of age). No effect of age was found on the mean score. In addition, no floor or ceiling effects were observed (Multimedia Appendix 2).

It should be noted that several technical issues occurred during the first 2 weeks owing to the wide variety of tablet operating systems. This situation resulted in the deployment of corrective patches, but owing to the correction delay, it may have differentially altered one child's experience relative to another's. To improve the user experience, phone calls were systematically conducted to interview families, determine potential problem areas, and gather feedback for improvement. Parents consistently highlighted the recreational side of the game and its impact on the children's self-confidence. A survey of 200 users, provided in Multimedia Appendix 1, also indicated that 96% (192/200) wished to continue using Mila-Learn after the COVID-19 pandemic. However, they also provided significant feedback (164/200, 82%) to improve the game. Multimedia Appendix 3 [57] presents the most significant feedback with a frequency of ≥10 occurrences. We classified it according to the criteria by Morville [56], which distinguish 7 dimensions: usefulness, usability, findability (the ease of locating a feature or a piece of context), credibility, accessibility design, attractiveness, and value [48]. Usability was questioned in several comments, such as "the detection of movements should be improved," "sound detection needs to be improved," and "the game needs to be better adapted to the child's difficulty profile." Accessibility was also questioned as several parents indicated that "the writing could benefit from being larger and the display of dialogues slower."

Mila-Learn Description Adjustments Following Study 1

Design Framework

On the basis of the feedback obtained during study 1, we made several modifications to Mila-Learn. To improve accessibility, the first modification was to offer the player the choice between several fonts, including OpenDyslexic. This choice is reversible throughout the game. We also improved sound and movement detection. A second significant choice was to distinguish the children's pathways according to their predominant disorders to facilitate their entry into the game and usability. For example, a player who indicated that they had dyspraxia at the time of registration was offered more moderate motor exercises (ie, Sing Lab), allowing them to enter the adventure before training on River Splash or Karate Fruits that are more challenging in terms of motor abilities. In contrast, a child with dyslexia could be offered River Splash from the beginning, with Sing Lab exercises being offered only afterward as Sing Lab involves the phonological loop.

To increase motivation and interest in the game, we provided new possibilities of personalization for the character: the player could choose the gender of the avatar, their color, and the color of the hat. We then increased the storyline with the help of a screenwriter. This modification improved the consistency of the story and made it more inclusive by adding new characters that could help the player during the game. A new companion named "Mila" appeared, who is a fairy representing the planet "Mila" where the story takes place. These modifications also influenced (1) the dialogues, which were shortened with the language adapted to children; and (2) the appearance of the notion of "rhythmic," which was introduced as a martial art based on rhythm to clarify the main goal of the game during the adventure.

Through this expansion, we created 6 new chapters. We maintained the same concept as the preceding version and gradually increased the level of difficulty during the progression of the game by increasing the speed of the rhythm and varying the type of rhythm clapped (ie, clapping notes, then eighth notes). We also created daily missions. These 4 daily tasks allowed the child to revisit games on which they had practiced in the past and where they encountered difficulties. This allowed us to directly address the tendency to forget what has been learned and allowed for longer practice with Mila-Learn.

Description of the Tasks

Finally, we made structural modifications to the proposed tasks to ensure the game's fluidity and improve motor interactions. First, we changed the way children had to answer during Clap Trap. Instead of clapping both hands, which was recorded using the microphone, we changed the child's interaction with the SG to synchronously tapping both hands on the screen (and, therefore, we used a touch recording). Second, Follow me was extensively modified to be more understandable and involve the child more on a motor level. The interaction was changed from a passive mode (one contact pressure) to a more active hand clapping measured using the microphone. The child did not perform the task all at once but interacted with the character, who gave them instructions that the child reproduced on the principle of call and response. Specific music was created for the game. As a consequence, Follow me was renamed Clap Hero. Finally, we modified the way children had to answer during Fruity Jump—children's interaction with Mila-Learn changed from tapping to shaking the tablet, which was measured using an accelerometer. Table 2 summarizes the changes made in the final version of Mila-Learn.

Table 2. Players' recorded responses and game parameters in the final version of Mila-Learn.

Task	Type	Interaction	Capture technology	Songs	Tolerance threshold
Clap Hero	*Call and response* [a]	*Clapping hands*	*Microphone*	*Customized*	• Perfect: 0.1 s before or after the beat • Good: 0.15 s before or after the beat • Correct: 0.25 s before or after the beat
Clap Trap	Last beat	*Tapping on the left and right side of the screen*	*Touch*	Commercial	• Perfect: 0.1 s before or after the beat • Good: 0.15 s before or after the beat • Correct: 0.25 s before or after the beat
River Splash	Last beat	Shaking tablet	Accelerometer	Commercial	• Perfect: 0.1 s before or after the beat • Good: 0.15 s before or after the beat • Correct: 0.25 s before or after the beat
Sing Lab	Call and response	Singing	Microphone	*Customized*	• Pattern: 0.15 s before or after the beat and up to 30% of the note duration • Song duration: the note must be sung at least 60% of the time
Fruity Jump	Call and response	*Shaking tablet*	*Accelerometer*	Customized	• Perfect: 0.2 s before or after the beat • Good: 0.25 s before or after the beat • Correct: 0.3 s before or after the beat
Karate Fruits	Last beat	Punching	Webcam	Customized	• Perfect: 0.08 s before or after the beat • Good: 0.14 s before or after the beat • Correct: 0.3 s before or after the beat

[a]Italics indicate game and functional changes that were introduced compared with the Mila-Learn second version summarized in Table 1.

Usability Study

This usability study focused on a sample of 98 children (mean age 9.05; SE 2.4 years), and we had both their reported diagnoses and game performance over time. These 98 children completed 3922 games. The linear mixed models yielded the following significant results. First, we found that the performance of the children significantly improved over time (β=.02; t_{3268}=2.68; *P*=.007). That is, there was an increase in the performance score by an average of 5 points after 250 levels were played.

Second, we explored whether declared diagnosis and age influenced the average performance of the children. Table 3 summarizes the results. We found that older children performed better than younger children. One year of age increased the normalized performance score by 1.08 points (meaning 1.1% of the maximal range). In addition, children with dyslexia and ADHD performed significantly better than those with other diagnoses (performance improved significantly faster in children with ADHD, β=.06; t_{3754}=3.91; *P*<.001, and slower in children with dyslexia, β=−.06; t_{3816}=–5.08; *P*<.001). Having dyslexia increased the normalized performance score by 2.81 points (meaning 2.8% of the maximal range) compared with children without dyslexia, whereas having ADHD increased the normalized performance score by 4.16 points (meaning 4.2% of the maximal range) compared with children without ADHD. In contrast, children with executive function impairment and dysgraphia performed significantly worse than those with other diagnoses. Having dysgraphia decreased the normalized performance score by 2.06 points (meaning 2.1% of the maximal range) compared with children without dysgraphia, whereas having executive function impairment decreased the normalized performance score by 3.26 points (meaning 3.3% of the maximal range) compared with children without executive function impairment.

Finally, we also tested whether progress over time statistically interacted with the declared diagnosis. We found that children with ADHD progressed faster over time than those with other diagnoses (β=.06; t_{3754}=3.91; *P*<.001) and that children with dyslexia (β=−.06; t_{3816}=–5.08; *P*<.001) and executive dysfunction (β=−.03; t_{3805}=–2.09; *P*=.04) improved less over time than those with other diagnoses. We found no significant interaction between time and a diagnosis of dysphasia (β=−.01; t_{3816}=–0.68; *P*=.50), dyscalculia (β=.05; t_{3787}=1.46; *P*=.14), or dysgraphia (β=.00; t_{3816}=–0.1; *P*=.92).

Table 3. Average scores according to diagnosis during study 3 with the final version of Mila-Learn.

	Estimate (SE)	*t* test (*df*)	Pr(>|*t*|)
Intercept	37.83 (4.60)	8.23 (6.04)	<.001
Age	1.08 (0.15)	7.02 (2082.28)	<.001
Dyscalculia (yes)	−0.43 (1.03)	−0.42 (2081.02)	.68
Dysgraphia (yes)	−2.06 (0.79)	−2.60 (2084.61)	.009
Dyslexia (yes)	2.81 (0.70)	4.03 (2087.52)	<.001
Dysphasia (yes)	−0.51 (0.93)	−0.54 (2086.54)	.59
ADHD[a] (yes)	4.16 (0.61)	6.79 (2090.71)	<.001
Executive function impairment (yes)	−3.26 (1.36)	−2.40 (2086.78)	.02

[a]ADHD: attention-deficit/hyperactivity disorder.

Discussion

Principal Findings

The literature on SGs, especially when designed for a specific medical condition, is limited when it focuses on game design methodology or formal clinical validation [42]. In this paper, we described the process and empirical studies to address this issue for Mila-Learn, an SG based on rhythmic training for children with dyslexia. To do so, we placed the patient's experience at the center of the game construction while iterating with clinicians involved in treating children with dyslexia. In this paper, we described the different developmental phases that helped us design the game. We first constructed an initial prototype based on a literature review and with the help of clinicians specializing in learning disorders. Then, based on a first round of feedback from users and comments from professionals, we developed a first version of Mila-Learn for tablets.

In this version, we greatly improved the users' experience with the game by adding new gaming features to increase the motivation and engagement of players. We offered more possibilities for customization, created a storyline, and introduced humorous and friendly characters to align with children's interests [51,52]. Moreover, we adapted the difficulty of the game to enhance the learning possibilities of children by working on graphism and the instructions given to the children and by creating evolving tasks that gradually increased the level of difficulty [51,53,54]. With this second version, we adopted a user participatory design by inviting children, families, and professionals to test this version and send us feedback about their experience (feasibility study). User participatory design is a method that is currently gaining attention. Contrary to user-centered designs, which create games for a user, participatory design aims to construct the game with the users by collecting their experience and advice and then including them in the game [58]. It has been shown that participatory design promotes engagement of the user [52]. Indeed, collecting feedback both from families and children and from professionals is essential as professionals and families and children focus on different aspects of an SG and do not place the same importance on each feature [52]. We believe that this participative process helped us develop an SG that improved the experience within the game and the interest of families and children in Mila-Learn.

Regarding computational aspects, we also collected feedback that helped us resolve bugs and record the time spent on the game and the player's accuracy in each game. These features allowed us to follow children's interest in the game and their progression over time and demonstrate that progression occurred with Mila-Learn and was associated with age. Study 1 confirmed that children could engage with Mila-Learn for a rather long period and play at home without the need for an extra supporting person, suggesting that Mila-Learn was sufficiently motivating and adapted to this population. Children and their families appeared to be highly satisfied with the game.

Finally, following a third round of feedback from parents, children, and professionals, we developed a final version of Mila-Learn to improve accessibility and motivation for the player. We made structural modifications to the proposed tasks to ensure the fluidity of the game and improve motor interactions. We resolved most of the technical problems, which allowed us to conduct a real-life usability study of the Mila-Learn game during the second lockdown.

Comparison With Prior Work

In the usability study, we observed that children significantly improved their scores on the 6 games included in Mila-Learn. Although we cannot conclude that the rhythm abilities of the children improved based only on these results, we believe that the children learned how to use Mila-Learn and that they were increasingly accurate in responding to each game. However, the effect size was small, although it may have been underestimated as the difficulty in the games increased, which could have masked the children's progression. In addition, based on the diagnosis declared by the children's parents, we performed exploratory analyses to assess whether improvements over time were associated with the declared diagnoses. Linear mixed models showed that children's performance significantly increased over time, that scores were better for children with ADHD and dyslexia, and that performance improved significantly faster for children with ADHD and slower for children with dyslexia.

Regarding the average performance of children according to diagnosis, the results were very encouraging if we consider the relationship between reading impairments and diagnosis. On the basis of the literature, we expected reading impairments to be associated with dyslexia, attention deficit, and specific oral language impairment (dysphasia) [59,60]. In addition, we expected that severity would negatively influence performance. This is usually the case when children have dysphasia [61], executive function impairment [62], or multidimensional impairments [63]. The results were in line with these expectations. Children with dyslexia and ADHD showed a significantly better performance over time, whereas children with dysphasia, executive function impairment, and dysgraphia showed a worse performance. Of note, children with dysgraphia often have motor coordination disorders [64]. Finally, dyscalculia had no influence on Mila-Learn performance. In summary, the predictions according to diagnosis were in line with the hypothesis that Mila-Learn may improve performance in children with reading impairments. The fact that dyscalculia showed no specific effects and that the diagnoses associated with the highest severity (dysphasia and executive function impairment) showed less improvement followed our hypothesis [61-63,65]. We speculated that dysgraphia was associated with multidimensional impairments, including motor coordination disorder. This interpretation is based on the fact that recruitment for the study was based only on user reading impairments.

Regarding the average performance of children according to diagnosis over time (ie, the statistical interaction), the fact that performance improved significantly faster for children with ADHD and slower for children with dyslexia is not surprising as the perception of rhythm is impaired in children with dyslexia. In contrast, children with ADHD may have impairments in reading abilities but do not have specific deficits in rhythm and speech perception [57,66].

Strengths and Limitations

The exploratory studies presented in this paper have some limitations despite the promising results. On the one hand, some aspects of the game need to be improved.

First, we currently consider a "standard" latency of 20 ms, which corresponds to the estimated delay between the child's real input and the input processed by the operating system. In reality, each tablet may have unique differences. In the next version of Mila-Learn, we need to consider this unique latency to get as close as possible to the real performance of children. This adjustment might lead to more accurate measurements of children's interactions and, potentially, more tailored game experiences.

Second, the game gradually increases in difficulty with the progression of the player within the game. We integrated some specific pathways as a function of the difficulties that the children declared before starting the game (ie, children with motor difficulties do not start with games that require a high level of motor skills). However, the progression is predetermined and does not take into account the results of the player. In the next version of Mila-Learn, the difficulty of each game will automatically adapt based on the child's performance in the previous games using a specific algorithm [53], allowing for much better stimulation. By doing so, the game could offer a more individualized experience, potentially leading to more sustained engagement and greater benefits for the children.

Third, the age range of 7 to 14 years is wide as children's interests can vary greatly during these years. In a future version of Mila-Learn, the graphics and music will be adapted to the age specified by the child so that the game will be more suitable for their age. This may enhance the game's appeal to players across the entire age range, fostering increased engagement and learning.

However, our study was only exploratory in nature. First, even if the lockdown gave us the opportunity to have a large sample for exploratory studies, diagnoses were not clinically grounded and were only declared by the children's parents. Therefore, caution should be the rule when interpreting predictive models.

Second, there was no predefined design for the studies as the training was spontaneous and included no comparison with alternative treatment proposals. Therefore, the clinical interest of Mila-Learn for dyslexia cannot be established based on the results of the 2 exploratory studies presented in this paper.

Future Directions

To address the clinical relevance of Mila-Learn in relation to dyslexia, the next step will be to evaluate the effects of Mila-Learn in the context of a randomized controlled trial. Children with dyslexia based on objective clinical assessments will be randomized to Mila-Learn sessions or placebo game sessions that take place in the same universe but with different tasks. We will assess the evolution of reading skills from before to after training with the hope of greater improvements with Mila-Learn. On the basis of the exploratory studies, we calculated the number of patients per group that would ensure a statistical power of at least 85% for an effect size equal to 0.5 (moderate) when the changes in the experimental and control groups were compared. This calculation indicated that each group should have at least 73 children (ie, 146 children in total). This study started in September 2021 (Comité de Protection des Personnes registration 2021-A01709-32; ClinicalTrials.gov Identifier: NCT05154721).

Conclusions

We presented how we constructed Mila-Learn, an SG based on rhythm activities, to improve reading skills in children with dyslexia. We developed several versions of the game considering the literature, professionals' experiences, and users' feedback. We also conducted a usability and a feasibility study to evaluate each version of Mila-Learn. The results indicated that Mila-Learn was attractive and sustained the players' motivation and engagement for several months. Moreover, children were able to learn how to use the game, and their performance in the games improved with training. Future research will include (1) adapting to the latency of the electronic devices, (2) automatically adapting the games based on the player's performance, and (3) conducting a large randomized controlled trial to evaluate the impact of Mila-Learn on reading skills.

Acknowledgments

The authors would like to thank Valentin Begel for his counsel in the design of this project, the Le Kremlin-Bicêtre hospitals for helping them develop the first version of Mila-Learn, and the École Polytechnique for its financial support. The authors would also like to thank all the families, children, and professionals for their feedback and encouragement. Special thanks to the French Federation for Learning Disorders. This work was supported by the École Polytechnique (grant "Prix Gérondeau 2018"). The sponsors of the aforementioned study funding source were not involved in the study, writing of the report, or decision to submit the paper for publication.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

FV conceptualized the study with DC and CG, managed data curation, acquired funding, undertook the investigation, and contributed to software development alongside AY. AY participated in data curation, formal analysis, and software development. HP was responsible for formal analysis and visualization. DC further contributed to conceptualization and was involved in methodology, supervision, and the review and editing process. CG also took part in conceptualization, formal analysis, writing of the original draft, investigation, supervision, and the review and editing process.

Conflicts of Interest

FV reports a relationship with bMotion Technologies that includes equity or stocks. AY reports a relationship with bMotion Technologies that includes employment and equity or stocks.

Abstract

Background: Adolescence is a crucial phase for early intervention and prevention of mental health problems. Casual video games are popular and have promise as a novel mechanism for reaching young people, but this potential has seldom been explored.

Objective: This study aimed to explore the acceptability, feasibility, and possible indicators of therapeutic changes after playing a purpose-built novel casual video game (Match Emoji) with simple mental health and well-being content among young adolescents.

Methods: We conducted a single-arm, nonrandomized trial of Match Emoji with 12- to 14-year-old school students (N=45; 26 [57%] New Zealand European, 12 [26%] Māori; 7 [15%] Asian or Pacific; 27 [60%] boys, 3 [6%] non-binary). Participants were invited to play Match Emoji for 15 minutes, 2-3 times a week over 2 weeks (a total of 60 minutes). Acceptability was assessed through the frequency and duration of use (analytics analyzed at the end of the 2-week intervention period and at weeks 4 and 6) and through participant reports. The Child and Adolescent Mindfulness Measure (CAMM), General Help-Seeking Questionnaire (GHSQ), Flourishing Scale (FS), and Revised Children's Anxiety and Depression Scale (RCADS) were assessed at baseline and week 2 to indicate possible effects. Focus groups were held in week 4.

Results: Most participants (n=39, 87%) used Match Emoji for at least 60 minutes over the 2-week intervention, with 80% (36/45) continuing to play the game after the intervention period. Mean change (from baseline to 2 weeks) on each measure was 1.38 (95% CI –0.03 to 2.79; *P*=.06) for CAMM; 0.8 (95% CI –2.71 to 4.31; *P*=.64) for GHSQ; –1.09 (95% CI –2.83 to 0.66; *P*=.21) for FS; and –3.42 (95% CI –6.84 to –0.001; *P*=0.49) for RCADS. Focus group feedback suggested that Match Emoji was enjoyable and helpful.

Conclusions: The casual video game with mental health content appeared to be acceptable and provided a promising indication of possible therapeutic effects. This approach is worthy of further investigation.

Introduction

Mental distress and low well-being are common among adolescents [1-3] and appear to have increased over the past decade, at least in high-income nations [4-6]. Cognitive behavioral therapy (CBT) and psychotropic medications are recommended for young people experiencing mental health disorders [7,8]. Preventative programs that aim to buffer against higher levels of distress later in life also exist for young people

[9]. Nevertheless, structural and attitudinal barriers inhibit access to mental health support for many young people [10].

Digital mental health interventions (DMHIs) refer to specialized content, support, or therapy for mental health conditions delivered electronically to treat, alleviate, or manage symptoms [11]. DMHIs encompass various technologies, including computerized CBT programs, chatbots, virtual reality for mental health conditions, games for mental health, apps, and interactive web pages [12]. Systematic reviews have shown promising effects for specific DMHIs across various age groups [13,14], such as CBT therapies for anxiety and depression [15,16]. Quality DMHIs can address some of the challenges often impacting face-to-face treatments [17,18]. For example, well-designed DMHIs can be used by young people irrespective of their level of distress, and they can be scaled up at a low cost due to their reduced reliance on clinically trained professionals [19,20].

Although this method of delivering mental health content is promising, engagement with DMHIs outside trial settings is typically lower than in trials [16]. Even playful interventions, such as Pesky gNATs [21] and SPARX [22], designed to appeal to young people's interest in computer games, have had limited evidence of engagement [16]. In part, these findings may reflect mismatches between how end users engage with technology and the way tools are provided (eg, sessions approximating weekly face-to-face therapies may be a poor match with contemporary patterns of internet use) [16,23,24]. Moreover, a lack of appealing options, lack of trust, or uncertainty about digital tools for mental health purposes may create additional barriers [22-24]. Therefore, while DMHIs have a great capacity to address mental health needs, it is important to keep exploring new opportunities to improve engagement [19,25,26].

Casual video games (CVGs) refer to simple games that can be played in short bursts of time, require no specialized skills, are often used for relaxation [27] and distraction purposes [28], and are generally free or low-cost to download and play. Well-known CVGs include "Rise Up" and "Angry Birds." "Rise Up" has been downloaded over 10 million times on the Google Play Store worldwide, and "Angry Birds" is played for approximately 200 million minutes daily [29,30]. Given their popularity and potential therapeutic effects, CVGs may be an approach that could be explored for delivering mental health and well-being content [28].

We systematically reviewed the effects of CVGs on anxiety, depression, stress, and low mood [31]. We found that 12 of the 13 trials reported promising results on their respective outcome measures. Following this work, we developed simple prototypes of CVGs with mental health concepts based on the puzzle, word, and match-3 genres and reviewed these in focus groups and interviews with young adolescents [32]. Young people indicated interest in this idea, with a match-3–style CVG being preferred. Subsequently, a game designer was contracted to develop the first version of Match Emoji, a simple match-3 CVG that includes brief text-based mental health and well-being messages, which have been previously described [33]. In brief, this includes short "micromessages," which were developed using psychological well-being literature and were sometimes linked to gameplay, for example, "Great job focusing and matching the emojis!" and "Phew! Take a short breath to help focus again." Subsequently, we held think-aloud interviews [34] with a small group of young adolescents to refine components.

In this study, we aimed to conduct a small open trial to explore the feasibility of using Match Emoji to strengthen the mental health and well-being of adolescents in a school setting. Findings from the study can help develop the literature on this new possible method for delivering mental health and inform processes for a possible future randomized controlled trial.

Methods

Design

The recruitment procedures, sample size, and analyses differed from those planned and published in our protocol paper [35] due to COVID-19 pandemic–related restrictions. Each departure from protocol is documented in the relevant section below.

This feasibility study used a mixed methods design. Adolescents attending New Zealand intermediate and high schools were recruited to participate in this study. They were shown how to use Match Emoji and then asked to play for 15 minutes, 2-3 times a week over 2 weeks (a total of 60 minutes). Analysis of game use, analytic data, and focus groups were held with all participants to explore the acceptability of Match Emoji. The therapeutic potential of the game was assessed by changes in mental health and well-being, which were assessed by 4 validated instruments.

Recruitment

Before the onset of the COVID-19 pandemic, we developed a protocol to outline the guidelines for conducting the trial, including how participants would be recruited [35]. Initially, as 1 local secondary school had expressed interest in participating, we aimed to recruit students between the ages of 13 and 15 years from this school across 2-4 classrooms. However, several teachers had become ill during the recruitment phase, and the secondary school could no longer participate in the study. As such, we approached 2 secondary schools (students aged 12-18 years) and an intermediate school (students aged 12-14 years), which all expressed interest in participating in the study.

In the secondary school, we described the study to an assembly of over 400 students in years 9 and 10 (aged 12-14 years). Those interested in participating in the trial and with access to a smartphone or tablet were asked to take home information, an assent form, and a consent form for their parent or guardian. Of the 42 interested students, only 6 returned both forms. When recruiting participants in each intermediate school, the New Zealand government implemented restrictions on indoor face-to-face gatherings. At this time, indoor gatherings of up to 100 people were allowed. As such, instead of recruiting participants in an assembly, we delivered a 10- to 15-minute face-to-face presentation to students in each classroom, explaining the theory and research underpinning Match Emoji. In total, 39 returned the assent and parental consent forms. Given the primary aims, the inclusion criteria were students aged between 12 and 14 years who had access to a phone that could download Match Emoji and provided written consent from a parent or caregiver.

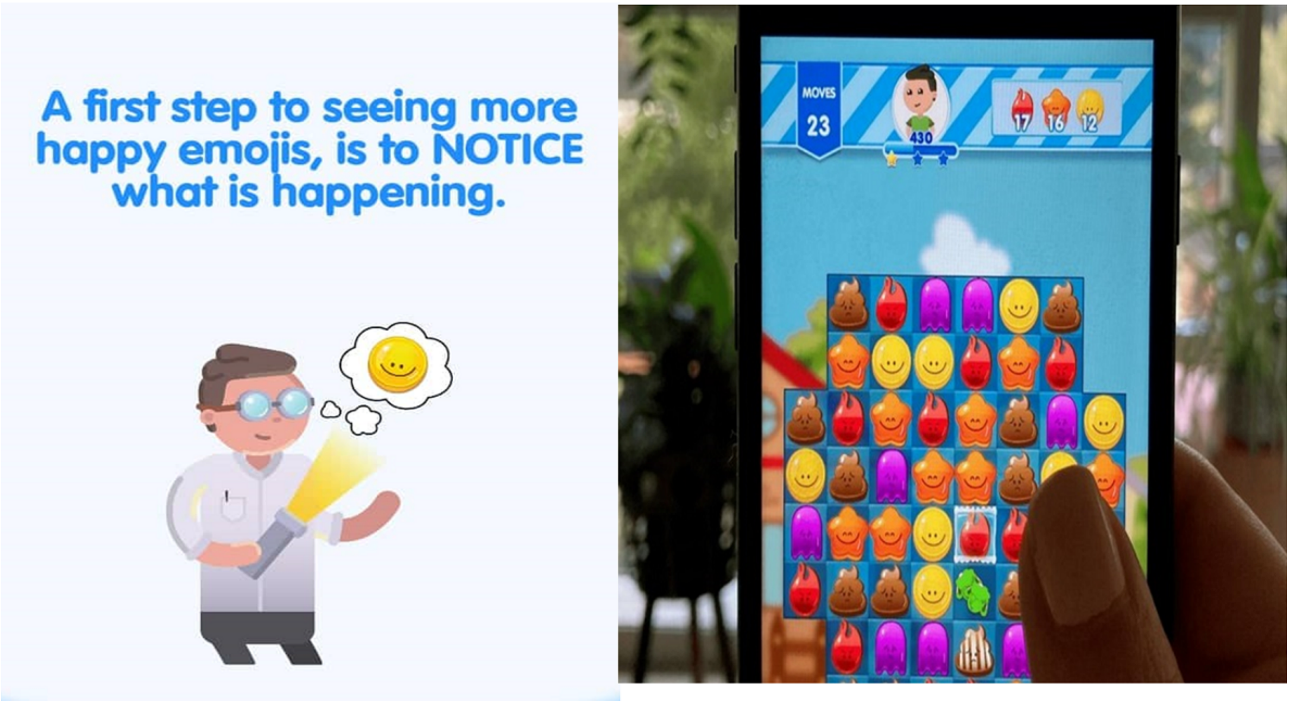
Study Procedure

Consenting participants completed the Child and Adolescent Mindfulness Measure (CAMM), General Help-Seeking Questionnaire (GHSQ), Flourishing Scale (FS), and Revised Children's Anxiety and Depression Scale (RCADS) at baseline. These assessments were completed in groups of 6 in the high school and 30 in the intermediate school. Students completed the questionnaires at their desks and were separated at least a meter apart from each other to protect privacy. Instructions on how to play and install the game were provided, and participants were given an opportunity to ask questions directly or email the primary researcher. Next, they were asked to play Match Emoji 2-3 times a week for a minimum of 15 minutes per session for 2 weeks (ie, a minimum of 60 minutes in total). Questions were repeated after the 2-week intervention period. All participants were invited to participate in focus groups held at each school 2 weeks later (4 weeks after the study began). After the study, *koha* (food and drink) was provided to acknowledge the student's effort. No financial incentives or gifts were provided.

The Intervention

The Match Emoji rationale, content, and processes have previously been described [33]. In brief, the micromessages in Match Emoji are based upon psychological well-being literature, specifically the *Five Ways to Wellbeing* [36]. As seen in Figure 1, these messages appear instead of in-game advertisements and function as prompts. For example, players are encouraged to read the message and practice skills including diaphragmatic breathing, noticing thoughts, or normalizing difficult emotions. In terms of the gameplay, users must identify and match 3 or more similar colored emojis together in rows or squares (a "match-3" game) to earn points. There are 6 different colored and shaped emojis, each representing an emotion or idea. The game has 99 levels, each designed to be completed within a few minutes, with a player advancing to the next level on completion of the current level. The gameplay becomes increasingly challenging as the player progresses.

Figure 1. Screenshot of the Match Emoji video game.



Measures and Outcomes

Demographic data were collected at baseline. Students who reported more than 1 ethnicity were categorized using the New Zealand Census ethnicity prioritization method [37].

Acceptability was assessed by the proportion of approached schools who agreed to participate, the number of participants who are able to download the game on their phone and those who fully participated in the study, and student feedback in focus groups. At week 4 (ie, after the intervention period), all participants were invited to take part in a 45-minute focus group at their school to explore their views of the intervention. Questions included (1) What parts of the game did you like? (2) What parts of the game could be improved? (3) What did you learn from playing the game? (4) Did you try and use any of the ideas from the game, and if so, which ones? and (5) Do you think you will continue to play Match Emoji? A general inductive approach was used to analyze the data from the focus groups [38]. The first author (RP) read participants' responses several times to identify emerging themes and categories from the raw data. A research assistant read through the raw data to ensure the themes reflected the essence of the category. Appropriate quotes that conveyed the key core themes were recorded and integrated into the results. Lastly, game analytics for minutes played and the number of sessions were recorded on the Unity platform [39]. Unity is a secure platform for creating and operating interactive games.

The secondary outcome measures assessing therapeutic potential were changes from the pre- to postintervention (baseline and 2 weeks) time period on mental health and well-being domains calculated from the CAMM, a 10-item instrument measuring acceptance and mindfulness for use with children and adolescents aged 10 between 17 years; the GHSQ, which measures formal help-seeking intentions for nonsuicidal and suicidal problems; the 8-item FS, which measures self-perceived success in important areas such as relationships, self-esteem, purpose, and optimism as a single psychological well-being score; and the RCADS, a 47-item youth self-report questionnaire with subscales, such as separation anxiety disorder and generalized anxiety disorder.

The specific mental health and well-being domains assessed were mindfulness derived from the CAMM, help-seeking from the GHSQ, psychological well-being from the FS, and overall anxiety and depression score from the RCAD. Pretest and posttest summary statistics (mean, median, range, and SD) were computed using the R software (R Foundation for Statistical Computing) developer package. Data were assessed for normality using the Shapiro-Wilk normality test. Since data were not normally distributed, the nonparametric Wilcoxon signed rank test was used to compare the means between pairs of values (pre and post).

Ethical Considerations

This study received ethics approval from the New Zealand Health and Disability Ethics Committee (21/NTA/34) on May 28, 2021. Data was de-identified and all participants provided informed consent. No financial compensation was provided to the study participants.

Results

Participants

Of the 45 adolescents who participated in the study (mean age 12.5, SD 0.33; range 12-14 years), 26 (57%) were New Zealand European, 12 (26%) were Māori, and 7 (15%) were Asian or Pacific. As seen in Table 1, the majority (n=27, 60%) were boys, while 15 (33%) were girls and 3 (6%) were nonbinary.

Table 1. Demographics of participants (N=45).

Characteristic	Value
Age (years)	
Mean (SD)	12.5 (0.33)
Range	12-14
Gender, n (%)	
Boy	27 (60)
Girl	15 (33)
Nonbinary	3 (6)
Ethnicity, n (%)	
Asian	3(6)
Māori	12 (26)
New Zealand European	26 (57)
Pacific	4 (9)

Acceptability

On average, each participant played 7.5 sessions for 24 minutes across the 2 weeks, comprising 180 minutes in total. In addition, data recorded from the focus groups suggested that, on average, participants completed 50 out of the 99 available levels during the 2-week duration of the study. Most participants in the focus groups said they would continue playing the game after completing the study. A total of 38 (84%) participants said they "would" continue to play the game, while 5 (11%) said they "might" continue to play. Only 2 (4%) participants said they would not continue to play the game after the trial. In addition, 36 (80%) reported playing Match Emoji after week 4, and 32 (71%) were still playing after week 6, according to game analytics from the Unity Platform. Findings from the focus groups suggested that participants enjoyed playing Match Emoji for several reasons. First, participants enjoyed the convenience of the game. For instance, many participants reported playing Match Emoji across multiple environments, including waiting rooms at the dentist, bus stops, and long car rides. As no internet connection was needed, participants could access the game whenever they wished. A participant explained, "I could play the game even when there was no Wi-Fi," while another said, "The game was really good when waiting for appointments (be)cause it could distract me for a bit and didn't use up data."

Second, many participants reported enjoyment from playing the game. They described this enjoyment as stemming from game features such as increasing levels of challenge, the variety of emojis, and clear goals: "it was fun (be)cause the game got harder, but you knew what you had to do." While there was some level of challenge, the simplicity of the game allowed students to bypass traditional barriers to CVGs, such as instructional videos. One participant described Match Emoji as a "super easy game to understand and play." A smaller group of participants also provided suggestions about game features. This group appeared to be more frequent users of CVGs, as they provided recommendations based on other games they had played. One participant suggested, “You could add more rewards or more characters and then get more power-ups like Fortnite,” while another recommended, “coins, customization, themed music, and bonus rounds... add stuff like they have in other casual games.”

In general, participants liked the subtle aspect of accessing mental health content. As 1 participant mentioned, “the messages are a nice way of getting mental health information out there that isn’t in your face.” There was a high consensus that they preferred micromessages over typical in-game advertisements. However, some were initially skeptical about their value, “the messages were cringe at first but got way better.”

Of the intermediate and secondary schools approached to participate in the research, only 3 (25%) of the 12 took part in the study. Only 3 (7%) out of the 45 participants could not download Match Emoji onto their phones. In each case, this was because their phone had limited capacity to download the necessary software. All participants completed baseline and follow-up assessments, but several needed clarifications on wording related to the RCADS questionnaire items.

Indicators of Possible Effects

As seen in Table 2, a small positive change was observed on the CAMM (mean difference 1.38, 95% CI –0.03 to 2.79) and on the RCADS (mean difference 3.42, 95% CI –6.84 to –0.001). In focus groups, when asked, “What did you learn from playing the game,” a number of participants answered that playing the game was helpful for their mental health and well-being: “I reckon playing the game for a bit of time was helpful for my mental health (be)cause it took my mind of stuff.” When asked, “Did you try and use any of the ideas from the game, and if so, which ones?” Several participants reported using specific skills suggested in Match Emoji: “Once when I started to think about annoying stuff, I tried the breathing thing, and it was actually pretty helpful,” and “I remember I got pretty mad at my brother and used the noticing a thought approach.”

Table 2. Changes in mental health and well-being indicators of adolescents aged between 12 and 14 years after 2 weeks of playing Match Emoji (N=45).

Outcome	Baseline, mean (SD)	Postintervention, mean (SD)	Mean differences (95% CI)	*P* value
CAMM[a]	22.44 (8.35)	23.82 (8.93)	1.38 (–0.03 to 2.79)	.06
GHSQ[b]	62.89 (21.96)	63.69 (23.30)	0.8 (–2.71 to 4.31)	.65
FS[c]	41.71 (11.58)	40.62 (12.07)	–1.09 (–2.83; 0.66)	.22
RCADS[d]	46.24 (26.39)	42.82 (26.49)	–3.42 (–6.84 to –0.001)	.049

[a]CAMM: Child and Adolescent Mindfulness Measure (mindfulness).

[c]FS: Flourishing Scale (psychological well-being).
[d]RCADS: Revised Children’s anxiety and Depression Scale (overall anxiety and depression).

Discussion

Overview

In this study, we found that a CVG with psychological well-being concepts (Match Emoji) was a new and engaging mechanism of change that provided a promising indication of possible therapeutic impact. Most participants played more often and for a longer period than was requested for the study. Indeed, most participants continued to play in week 4. Small improvements in mindfulness assessed by CAMM and a small decrease in overall anxiety and depression assessed by RCADS were recorded. Given these promising changes, participants may have learned skills related to reducing their level of anxiety through playing Match Emoji. The findings of this small open feasibility trial indicate that the Match Emoji CVG was an acceptable way to support mental health and well-being in adolescents aged between 12 and 14 years.

Participants reported a high level of acceptability with Match Emoji, as evidenced by the game analytics, qualitative feedback, and the large portion of participants who were still playing the game in weeks 4 and 6. The percentage of participants who stated they continued to play Match Emoji even after week 6 of the study (n=32, 71%) is contrary to the poor retention rate typically found across the range of digital interventions. Real-world data on user engagement with popular mental health apps suggest that a small portion of users stay engaged with digital health interventions [16]. For example, once a health app is downloaded, approximately 4% of users continue to use the app after 15 days [24]. It is possible that the ongoing consultation with end users from the beginning of the development of Match Emoji, the simplicity with which CVGs can be played “on the go,” across environments with no Wi-Fi, and how playing CVGs fits with adolescents’ current behavior patterns may have been attributed to the high level of acceptability and engagement. That is, as many adolescents already play CVGs [32], there is less effort required to learn and change existing ways of engaging with technology. Data from the focus groups corroborated these findings. More specifically, participants mentioned they enjoyed playing for short periods across environments in comparison to computer games or those mobile phone games that require data to access. This is consistent with our previous work [32] and research [19], which suggests young adolescents tend to prefer brief therapeutic encounters. Moreover, Match Emoji enables large portions of the population to receive the same content irrespective of their proficiency with gaming or access to the internet, addressing a significant barrier to equity and engagement with DMHIs [11].

Our finding that most participants preferred micromessages over typical in-game advertisements is consistent with research assessing how in-game advertising in the form of short videos is distracting and can lead to disengagement, particularly among young people who often have a relatively short attention span [40,41]. Although paid versions can avoid advertisements, young people are reluctant to pay for them [41]. Thus, Match Emoji represents an opportunity for public health interventions to provide appealing free CVGs that replace the advertising with health-related micromessaging that is not distracting, annoying, or potentially harmful, as is the case with in-game advertising.

Similarly, diverse preferences were found with gamification elements of Match Emoji. The various preferences toward micromessages and game features among participants are consistent with the literature that suggests adolescents have different opinions about the type of DMHI they are attracted to [42,43]. Thus, while some adolescents may be frequent CVG users and interested in gamification elements, others may be less focused on these features and more attracted to learning about mental health and well-being [44]. In essence, opportunities to embed therapeutic processes within game elements are plentiful when researchers and game developers collaborate and are creative.

The protocol and implementation of this study were completed during the COVID-19–lined social distancing practices, which resulted in frequent changes to the restrictions on the size of inside gatherings and how educational facilities operated. Apart from the implications of the pandemic, 3 participants in the study could not download Match Emoji. This was because their phones lacked the storage capacity required to download the latest software and the game. Future research could use methods to compress digital mental health apps such as Match Emoji. In this way, the size of the app may better align with the capacity of users' technology. In addition, some participants struggled to understand several questions on the RCADS. These questions were discussed in more detail with each participant to ensure they understood the meaning of each one. Despite these challenges, no significant issues occurred with conducting the study in a primary and intermediate school context.

Limitations

There are limitations to this study; these include departures from the protocol due to COVID-19 impacts, which resulted in a small exploratory open trial only. There were also limited resources to conduct the study; this meant that the first author (RP) introduced the game to participants, led the recruitment process, supported the completion of assessments before and after playing the game, and facilitated the discussions about the game. Thus, the interpretation of the students' feedback could be overly positive, and participants' opinions and thoughts could be influenced by social pressures, including normative and informative conformity.

Further, the self-assessment outcome measures relied on the comprehension skills of young participants. While some participants raised their hands when unsure of a question, others may have merely guessed. Nevertheless, the 4 assessments appeared to be easy to implement in a short amount of time. Third, when recruiting participants at the secondary school, only 6 (14%) out of the 42 participants who signed the assent form returned their parental consent form for reasons unknown, suggesting that a different process is needed to recruit older adolescents for future trials. Lastly, students were not recruited based on their level of mental distress. Therefore, the results may have been affected by floor effects, whereby their mental health and well-being scores were already good or optimal and thus unlikely to improve any further. Despite these challenges and preliminary results, these findings are of interest as this is the first study to assess the feasibility of a co-designed CVG with psychological well-being concepts.

Conclusion

Findings from this feasibility study suggest that Match Emoji, the purpose-built CVG with brief mental health messages, is promising as an acceptable and feasible approach for young adolescents. Future research should test clinical impacts through a randomized controlled trial. More broadly, the research also highlights the possibility of CVGs as a novel mechanism of delivering simple mental health and well-being messages.

Acknowledgments

We would like to acknowledge the young people who participated in the study and the teachers who helped with the recruitment process. This study was funded by Cure Kids (innovation seed fund: 3918).

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

RP and TF were involved in the conceptualization of the game and study. LTM and JM were involved in the methodology and formal analysis. All authors were involved in writing the original draft and reviewing and editing the paper. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

TF is a codeveloper of SPARX, a computerized cognitive behavioral therapy program for adolescent depression. The intellectual property for SPARX is owned by Uniservices at the University of Auckland, and codevelopers can benefit financially from the licensing of SPARX outside of New Zealand.

Abstract

Background: To the best of our knowledge, no specialized research has been conducted to address ailurophobia (fear of cats) in Iran or globally. This has driven our project, along with the prevalence of ailurophobia and the absence of a gamified virtual reality exposure therapy (VRET) that incorporates affordable and easily accessible biofeedback (BF) tools. We hypothesize that a gamified VRET augmented with BF will yield more positive effects than a similar device lacking BF.

Objective: This study primarily focuses on the development and preliminary evaluation of a smartphone-gamified VRET integrated with BF, targeting animal phobia, with a specific case study on ailurophobia. The secondary objectives are using affordable and readily available BF found in devices such as smart bands and smartwatches and creating a mobile virtual reality gamified app to improve patients' adherence to treatments while simultaneously enhancing the app's accessibility, scalability, and outreach.

Methods: Evaluations encompassed 3 methods. First, we identified the tool's potential positive effects on phobia interventions, exploring 4 effects: intrinsic motivation, simulation of fearful situations, management of stressful circumstances without therapists' presence and mitigation of catastrophic thoughts, and preliminary effects on ailurophobia treatment. Participants were divided into BF and non-BF groups. Second, we gathered user preferences and opinions about the treatment. Third, we conducted heuristic evaluations using 44 heuristics from existing system usability scales assessing user interfaces, virtual reality platforms, and video games' playability. To interpret the data, mean scores; ANOVA, single factor; and ANOVA, 2-factor with replication were used. A total of 29 individuals were identified, of which 10 met the eligibility criteria or were accessible.

Results: The smartphone-gamified VRET augmented with BF exhibited better results on the identified effects compared with the non-BF version and contributed to normalizing encounters with cats. Moreover, 41 of the 44 heuristics achieved a percentage above 62%, indicating its potential as a therapeutic product and its ability to enhance patient adherence to treatments. Patient preferences on the treatment and its strengths and weaknesses were provided for further improvement.

Conclusions: The tool has the potential to evolve into a comprehensive solution by incorporating various types of cats and their behaviors, simulating environments in which they are commonly found, and enhancing its appeal through an increased sense of adventure without inducing unrealistic fears. By adapting fear elements, the game can be tailored to treat various animal phobias.

Phobia-focused games should avoid action and combat scenarios to prevent reinforcement of fear responses. After rigorous evaluation, further exploration is required to provide remote use beyond clinical settings.

Introduction

Specific Phobia and Available Therapies

Specific phobia is the most common anxiety disorder, with a lifetime prevalence of 12.5% [1]. It is characterized by an extreme and persistent fear of a specific object or situation [2], leading to substantial disruptions in daily life and heightened anxiety. Many individuals restructure their lives to evade their fears over extended periods [3,4]. Prolonged phobia detrimentally affects academic, social, and family aspects, compromising overall quality of life [5]. Situational (eg, fear of enclosed spaces and flying), natural environment (eg, fear of heights and storms), animal (eg, fears of snakes, spiders, and cats), and blood or injection or injury (eg, fears of medical procedures and seeing blood) fears are subtypes of specific phobias, with animal and natural environment phobias being more prevalent [3].

Phobia interventions are categorized into exposure therapies (eg, direct in vivo exposure, systematic desensitization, imaginal exposure, and virtual reality [VR]) and nonexposure approaches (eg, cognitive therapy and progressive muscle relaxation). There has been a trend toward adopting brief, intensive, or concentrated treatments to manage anxiety [5]. Among the available treatments, exposure therapies are the most commonly used approach for specific phobias [6]. However, although specific phobias are highly treatable, only 31% of patients seek treatment and, among those, only 43.4% seek mental health services [3]. Moreover, some patients might be unable to complete the treatment because of severe reactions, resulting in an attrition rate of 45% [3,7]. In total, 3 main factors contribute to this percentage [7]: (1) perceiving treatments as highly aversive and frightening; (2) the need to visit clinics throughout the treatment, causing relationship and ethical issues, such as perceived cruelty when therapists intentionally evoke fear; and (3) the lack of appealing treatments.

Gamified VR Exposure Therapies Augmented With Biofeedback

To overcome the limitations of exposure therapy methods, incorporating new technologies becomes imperative. Gamification, VR, and biofeedback (BF) are promising options. However, our research indicates that few studies have simultaneously used these technologies for specific phobias. Virtual reality exposure therapy (VRET) uses 360° computer-generated simulations [8,9] similar to traditional exposure therapies [2]. Meta-analyses have shown that VRETs are effective and their performance can rival standard exposure therapies [2]. VR's application in cognitive impairment, anxiety disorders, pain management, phobias, posttraumatic stress disorder, rehabilitation, and eating disorders, among others, has surged because of its immersive realism [8,10]. To treat phobias, VR is a safer, less embarrassing, and cost-effective solution by simulating fear-inducing situations in a controlled environment [8,9,11]. However, VR alone may not address all exposure therapy disadvantages, and enhancing the attractiveness of VRETs is crucial for treatment success. Researchers have explored the potential of gamified VRETs in treating phobias [2,12,13]. Gamification, a strategy derived from video game–based approaches, has proven successful in achieving serious objectives across various fields, including the workplace [14], education [15], marketing [16], mental health [17-19], learning disabilities [20,21], and lazy eye treatment [22]. The primary inherent feature of digital games is their high-level motivational potential [23]. Video games' appeal, engagement, and effectiveness encourage players and frequent use [18]. Attractiveness is beneficial for overcoming people's reluctance to seek treatment, broadening the reach of gamified interventions [18]. The engaging nature of gamification enhances users' experiences, as players are driven to win, explore stories, and ultimately reduce attrition rates [12,18,24]. The effectiveness aspect offers opportunities for achieving serious objectives such as behavior changes [18]. In a gamified product, elements such as scores, badges, and levels are integrated from games into nongame contexts, while not necessarily offering a complete gaming experience [18,25].

Human emotion recognition sensors or BF is another technology that can enhance gamified interventions. This technology serves 2 crucial purposes. First, it boosts their level of attractiveness by leveraging a strategy commonly used in video games to increase engagement [26]. Second, it addresses some of the limitations of traditional methods by potentially reducing or eliminating the need for therapists' constant presence. These sensors work by measuring various body parameters or electrical impulses in the nervous system to identify different emotions and track their changes [27]. Common techniques include electroencephalography, skin resistance measurements, blood pressure, heart rate (HR), eye activity, and motion analysis. With advancements in chipset manufacturing, BF has become more accessible, portable, efficient, and affordable. Users can easily access their data, thereby enabling self-regulation and monitoring. These technologies are incorporated into smart wristbands and watches to help individuals regulate anxiety in their daily lives. BF therapies have shown positive effects in treating conditions such as migraines [28] and attention-deficit/hyperactivity disorder in children [29].

Objectives

The primary aim of this study was to develop and conduct a preliminary assessment of smartphone-gamified VRET augmented with BF for the treatment of cat phobia (ailurophobia). We hypothesize that this tool will outperform gamified VRET without BF in various aspects. Limited evidence exists on animal phobia in Iran, particularly ailurophobia. Observations at the Cognitive and Brain Clinic in Tehran revealed a substantial prevalence of this phobia, as reported by the fourth author, who is a cognitive expert and psychologist attending to cat phobia patients daily. Owing to the abundance of cats in most Iranian cities, encounters are inevitable, resulting in daily challenges for patients walking on the streets and alleys. The secondary objectives were as follows:

1. Using affordable and accessible BF tools in devices such as smart bands and smartwatches to serve as both BF and a game mechanic, enhancing engagement and efficacy.
2. Developing a mobile VR–gamified app to enhance patients' adherence to phobia treatment and expand the app's accessibility, scale, and reach.

To evaluate the effectiveness of the tool, its potential positive effects on phobia interventions were examined. The tool's impact on the effects was examined by dividing the participants into BF and non-BF groups. In addition, we considered the playability and usability aspects of the tool, along with patients' preferences, to optimize its performance and enhance usability for future improvements.

Methods

Design and Development

Our primary objective was to present fear elements indirectly to the player, ensuring that interacting or not interacting with them would not affect the game's progress. The secondary objective was to create a general game design model that could be easily customized for specific phobias, particularly animal phobias. During the initial game development meeting, 2 game design experts (a game designer and a gamification expert) collaborated with 2 cognitive science experts (one of whom also specialized in cognitive games). They engaged in a discussion regarding the essential components required to simulate stress. Size, color, and behavior of the stimuli were introduced as fundamental elements for replicating the desired scenarios. The game team then devised the game stages using a maze design. In the second meeting, cognitive experts suggested simplifying the design to accommodate players of all ages. As it involved memory and problem-solving, it was rejected, leading to a more straightforward game plan that focused on finding lost objects in a park. In the third session, this plan received approval and was tested on a woman aged 40 years with cat phobia, who was selected based on her self-reported fear of cats. She stated, "I experienced a lot of fear during playing." In the fourth session, minor adjustments were made to the game. In total, 2 psychologists from Tehran University found the initial voice of the guide annoying, thereby hindering patient motivation. The overall view of the sessions is presented in Figure 1.

Our game's storyline was inspired by the "Hot and Cold" game. One group hides an object, and the other group should find it using verbal clues such as "colder" as they move away and "hotter" as they get closer. The experience is similar to that of a park with diverse paths. Players are on a quest to discover diamonds concealed within treasure boxes, all while walking along these pathways. Each game session comprises 4 short yet consecutive levels. At each level, players must determine their distance from each box by perceiving changes in the sound consistently played. Moreover, a hint ribbon shows the player's distance to the box for increased engagement. After locating the box, players must stay in front of it for a specific duration to open it, with the time increasing at later levels. The players must open the previous level's box to unlock the next challenge.

Regarding authors' concerns about spreading the game to individuals with phobias, smartphones were chosen as the primary platform. Using smartphones as a VR tool requires affordable mobile VR glasses, which are significantly cheaper than other options such as Oculus or HTC VR. The primary challenge in mobile VR is the user interaction limitations. The game uses Gaze, a pointer on the screen that allows users to interact through head movements, thus providing a mouselike experience. In addition, the game incorporates joysticks connected to the phone, thus offering more interactive possibilities.

The intensity of the fear elements must be balanced based on the game's progress and levels, as in previous studies [7,13]. The escalation of fear stimuli is determined by the following features, each with its own difficulty level. Moreover, these elements can be further amplified in tandem with player's advancement.

1. Visual elements: the fear-triggering elements include cat photos, fantasy cat models, low-poly cat models with minimal details, and high-poly cat models that closely resemble real cats. According to experts, individuals who fear something may also react to objects and shapes that resemble it. For instance, people who are afraid of cats might experience fear when encountering a cat picture or a furry object. This phenomenon is directly related to the degree and intensity of the individual's fear [30]. Figure 2 illustrates the game environment.

2. Fear elements' sound: the scary elements vary from silent to those with terrifying sounds. In intense situations, cats produce specific sounds that could heighten anxiety. The timing of when the sound is played also adds to the diversity. For example, when players are near a cat, the sounds it emits could intensify their fear.

4. The quality of fear elements' behaviors: studying the behavior quality of a stimulus is under investigation [31,32]. A cat jumping from one point to another evokes more fear than a cat simply standing still. Various animations were designed for 3D model cats. The fantastical cat playfully turns its head and randomly spins around. The low-poly cat remains stationary, solely turning its head. In the final level, the high-poly cat features 3 different animations. The first 2 animations portrayed the cat at rest, either shaking its tail and head or cleaning its paws. The third animation involves the cats' walking behavior.

5. Interactable elements: fear elements that respond to the player's presence add a sense of authenticity to the game, elevating immersion and allowing for anxiety manipulation. Cats may react by turning, approaching, or fleeing when a player gets closer. Both low-poly and high-poly cats respond to the

player's presence. The manner in which the elements react was also classified. Although the fantasy cat remains unresponsive, the low-poly cat acknowledges players by turning their heads and looking at them when they enter the zone. At the last level, the realistic cat not only faces the players but also follows them until they exit from its zone.

6. Fear elements' size: element size could also amplify fear. In the final level, some cats are larger, preparing players to confront more intimidating situations.

7. Fear elements' numbers**:** seeing numerous cats creates a feeling of being surrounded, indirectly encouraging players to confront their fear. As players approach the boxes, fear intensifies, peaking around those areas.

The quantity and type of elements can be customized based on players' preferences and conditions (Figure 3), which is beneficial when they need to concentrate on a specific scary element. Furthermore, a player who does not fear an element can eliminate it from the game.

A VR Android game was developed using the Unity game engine, incorporating the Amazfit Bip smartwatch. In anxiety treatments, HR variability is a common BF technique for stress management [33]. However, because of limitations in receiving these signals through conventional smartwatches and wrist bands, HR was used instead of HR variability. HR data are accessible in smartwatches through Bluetooth low energy technology [33]. A plug-in for the Unity3D game engine was implemented to integrate smartwatch data into the game. The player's HR was incorporated into the experience as a game mechanic. The HR was displayed on the corner of the screen. A total of three BF techniques were used in this study: (1) displaying changes in players' bodies to inform and manage anxiety [33]; (2) keeping HR within specific limits allows players to earn the game's prize, a diamond, promoting relaxation skills for stressful situations [34]; and (3) maintaining a low HR for a period allowed players to open boxes and collect more diamonds [33,35].

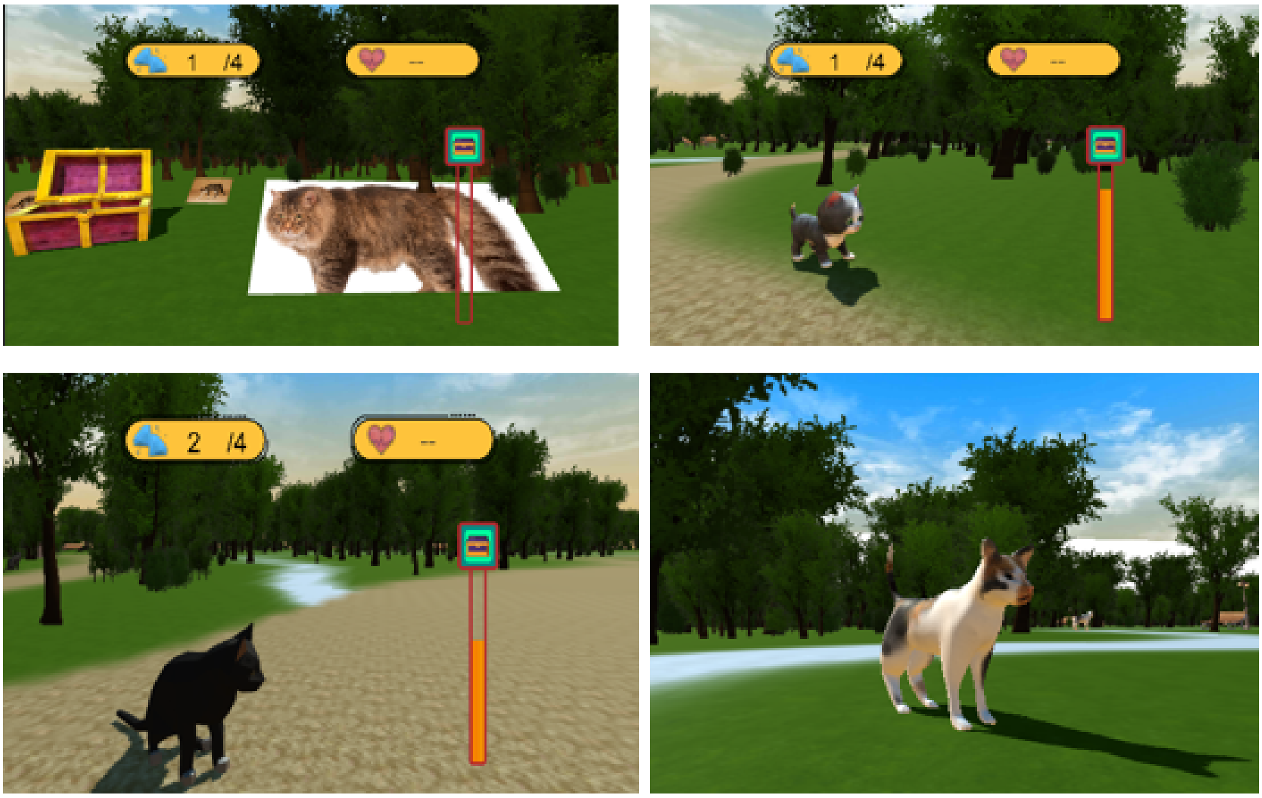

Figure 3. Images of the level customization menu.

Trial Design, Participants, and Procedure

Overview

In total, three methods were used to evaluate the tool: (1) identifying its potential positive effects it could have in phobia interventions. To assess the game's impact on these effects, participants were divided into BF and non-BF groups, with the only differences being the use of smartwatches; (2) gathering user preferences about the treatment; and (3) considering the tool's playability and usability aspects for subsequent optimization and improved usability.

Ethical Considerations

This study was approved by the Research Ethics Committees of the Institute for Cognitive Science Studies (IR.UT. IRICSS.REC.1401.047). Informed consent was obtained from participants. They had the freedom to withdraw from the study at any time. The participants' data were anonymized. To compensate for time, participants were informed that a smartphone-compatible version of the game would be provided free after its finalization.

Participants

The snowball method was used for recruitments. One attractive advertisement was prepared in Farsi and shared within various working, educational, and family groups on Instagram and

WhatsApp. Receivers were asked to help by sharing the advertisement with their own groups. Recruitment took place from September 8 to October 14, 2022, in 2 provinces in Iran: Lorestan and Tehran. Each test session lasted up to 3 hours, and the participants had the flexibility to choose the test location. Random assignment was used to allocate the participants to the study arms.

Inclusion criteria were (1) providing informed written consent, (2) understanding and reading Persian, and (3) scoring ≥55 on the Fear of Cats Questionnaire (FCQ). Exclusion criteria were (1) currently receiving psychological treatment for ailurophobia; (2) having another severe mental disorder (alcohol or substance abuse, psychotic disorder, dementia, or bipolar disorder); (3) diagnosed with a severe personality disorder; (4) experiencing depressive symptoms or suicidal ideation; (5) heart disease; (6) vision or balance problems affecting the VR experience; (7) pregnancies exceeding 3 months; and (7) fear of cats only in a few and exceptional cases. An image of participants is presented in Figure 4.

Figure 4. Depiction of participants.

Identifying the Positive Effects of the Gamified VRET Augmented With BF

Effect 1: Intrinsic Motivation

One primary positive effect that the app could have on phobia interventions is its ability to enhance intrinsic motivation. By incorporating gamification, VR, and BF, the app effectively motivated patients to actively engage in their treatment. We hypothesize that combining gamified VRET with BF will significantly increase motivation compared with a similar tool without BF.

To assess their impact on intrinsic motivation, we used subjective and objective measures. After each level, participants completed a 10-item questionnaire that was previously used to evaluate subjective engagement [36-39].

Participants played a minimum of 5 levels and completed the intrinsic motivation questionnaire after each level, except for the first. First-level data were excluded because of participants' unfamiliarity with the experience. For the training step, the picture level of the game with 8 cat pictures was predetermined. The other settings regarding the type and quantity of stimuli for mandatory games are as follows:

- Game 1: fantasy model with 13 cats
- Game 2: low-poly model with 19 cats
- Games 3 and 4: high-poly model with 23 cats

We deliberately chose the last 2 steps in the same manner to examine the impact of repetitive tasks on the participants.

After the mandatory games, participants had the option to play the game for up to 4 additional times. During the voluntary sessions, participants were allowed to choose the type and number of cats, but the number of cats had to be selected in ascending order. In these sessions, we used a shorter version of the intrinsic motivation questionnaire with only 5 items, as used in Lumsden et al [36].

Effect 2: Simulating Fearful Situations

For phobia treatments to be effective, the game should evoke fear among individuals. To evaluate this, both groups were asked to rate their anxiety levels on a scale from 1 ("no anxiety") to 10 ("extreme anxiety") after any mandatory and voluntary sessions (except the first level).

Effect 3: Controlling Stressful Circumstances, Eliminating Therapists' Presence, and Mitigating Catastrophic Thoughts

The game enables participants to implicitly learn relaxation techniques while confronting their fears. The box-opening mechanism involves standing in front of the box for gradually increasing durations. This combined approach, along with BF, has the potential to reduce the need for therapists' presence.

After the experiments, the participants were asked two questions: (1) How well do you think you could manage your stress when dealing with a real cat after using the gamified app? (2) To what extent can our game eliminate the need for operators? The app's attractive and fantasy environment was expected to alleviate catastrophic thoughts. Participants were also encouraged to share any positive signs of reducing their frequency of thinking about their fears.

Effect 4: Preliminary Effects on Ailurophobia Treatment

The study used before and after assessments with the State-Trait Anxiety Inventory (STAI) and FCQ to measure the game's impact on phobia symptom changes. The STAI questionnaire comprises 40 questions, measuring state (S-scale) and trait (T-scale) anxiety using a 4-point Likert scale. Only the S-scale was used in this study. The evaluation of state anxiety can be used for any situation with a time interval determined by a researcher or a clinical specialist. Mahram developed the Persian version of the STAI, and its internal consistency was confirmed for the S- and T-scales (Cronbach α of .91 and .90, respectively) [40]. Another Iranian study also reported high reliability for the S- and T-scales with Cronbach α values of .93 and .90, respectively [41]. The FCQ questionnaire was derived from the Fear of Spiders Questionnaire (FSQ) to assess cat phobia, with all instances of the word "spider" replaced by "cat." Furthermore, the question format was adjusted to suit the assessment of the cat phobia. The FSQ is an 18-item tool scored on a 7-point Likert-type scale to measure the level of spider phobia, yielding a total score ranging from 18 to 126. The FSQ demonstrates excellent internal consistency with Cronbach α ranging from .88 to .97 [42,43] and good test-retest reliability [42]. The FSQ has been used in previous studies for various phobias such as cockroaches [7,44,45], rats [46], and snakes [47].

After the games, each group of participants was instructed to play 2 levels of the game as the opposite group did. They were then asked to answer the following questions: (1) Which experiences do you prefer? (2) Which experiences had more novelty and were more attractive to you? (3) Which experience was more effective for improving your problem?

Patients' Preferences About the Designed Treatment

To gather patients' opinions on the implemented treatment, an adapted preference questionnaire [48] was used. This 6-item questionnaire focused on patients' preferences regarding the types of cat models, their behaviors, sounds, and sizes. For example, the questions related to cat models are as follows: (1) If you could choose among the cat models, which one would you prefer? (2) Which cat model do you think would be more effective in helping you overcome your problem? (3) Which cat model do you find more logical for aiding in your progress? (4) Which of these cat models do you perceive as more aversive? (5) Which cat model would you recommend to a friend facing the same problem? (6) Are there any cat models missing in the game?

Heuristics Evaluations

The playability and usability aspects of the tool were examined through heuristic evaluations designed as semistructured interviews to optimize its performance and enhance usability. Participants completed a 5-Likert questionnaire covering user interfaces, VR experiences, BF, and game playability. Participants had the opportunity to provide additional comments. The evaluations incorporated 44 heuristics from studies [49-52]. We used Nielsen heuristics [49,50] to assess the interfaces, along with modified Nielsen principles for VR platforms [51]. In terms of game playability, a comprehensive evaluation was necessary to assess additional features, including gameplay, story, and mechanics, which went beyond simple interface usability evaluation [52]. We used the heuristic principles of playability introduced in [52], which carefully examine the various components of a game in terms of playability and enjoyment for the player, encompassing gameplay, mechanics, usability, and game story. In this study, we used the first 3 heuristics from this set.

Statistical Analysis

We evaluated the differences in subjective ratings of intrinsic motivation and levels of anxiety using ANOVA: 2-factor with replication of the total score, with session number as the time factor and task variant (the tool with and without BF) as the between-subjects factor. In addition, we used 1-way ANOVA with task variant as the between-subjects factor to investigate the effects of the tool on mitigating phobia symptoms. For analyzing the semistructured interviews, mean and SD scores were used.

Results

Participants

Of the 17 participants, 7 were excluded for (1) heart disease (n=1); (2) vision or balance problems (n=1; participants with VR-induced dizziness and severe nausea); (3) pregnancy (n=1); (4) personality disorders (n=1); and (5) fear of cats in specific situations (n=3; one was afraid of direct eye contact with cats, whereas 2 others were scared of black cats). Among the 10 included participants (Table 1), 1 individual had 2 other phobias: fear of public toilets (paruresis) and birds (ornithophobia), especially their beaks and legs. Another participant displayed general phobia of animals; even touching chicks elicited an electric shock response. In addition, the sight of cats, dogs (cynophobia) especially when they bark, and foxes caused annoyance and discomfort for her. Interestingly, she was more afraid of kittens than fully grown cats. Another patient had cynophobia and ailurophobia. Finally, 1 participant had a phobia of space and galaxies (to the extent of avoiding space-themed movies) as well as chicks phobia and ornithophobia stating, "I am even afraid of a bird in a cage that might come out and harm me." This participant also avoided going to the park because of the fear of the animals. Given the prevalence of individuals experiencing multiple phobias, particularly fears related to various animals (zoophobia), such as cats, spiders, snakes, and dogs, it is crucial to explore the possibility of modifying the game to effectively address multiple types of phobias. The park environment appears to be conducive to addressing various animal phobias and specific phobias such as paruresis. Accessing 10 participants was hindered by the temporary filtering of Instagram in our country. In addition, 2 individuals declined to participate, expressing shyness and concerns about others noticing their phobia. Our observations suggest that men with ailurophobia conceal their fear more frequently. Notably, ailurophobia predominantly affected women, as 90% (9/10) of our participants were women (Table 1). Ailurophobia began in 70% (7/10) of the participants during childhood and 30% (3/10) during adolescence. The minimum and maximum ages of onset of phobia in the samples were 5 and 18 years, respectively. Regrettably, animal phobias in our country, particularly cat phobia, have been largely overlooked, leading individuals to live for many years in a completely curable condition without seeking treatment. Innovative and early interventions, for example, our tool, could treat patients from childhood when anxiety starts and reduce the negative impact of untreated phobias. There is a pressing need for screening and diagnostic games as a primary step, followed by therapeutic games. The main cause of participants' phobia stemmed from an unexpected childhood encounter with a cat.

Table 1. Participants' characteristics.

Characteristics	Non-BF[a]	BF
Age (years), mean (SD)	24 (7.31)	33.5 (7.16)
Female, n (%)	5 (100)	4 (80)
Video game playing hours per week, mean (SD)	6 (8.52)	1.5 (3.08)
Median level of education	Diploma degree	Master's degree
Years living with cat phobia, mean (SD)	15.6 (5.68)	21.6 (12.01)
Married, n (%)	2 (40)	2 (40)
The onset of phobia, n (%)		
Childhood	4 (80)	3 (60)
Adolescence	1 (20)	2 (40)
Youth	0 (0)	0 (0)
Adulthood	0 (0)	0 (0)
Age of onset of phobia (years), range	9-13	5-18

[a]BF: biofeedback.

Possible Positive Effects of the Gamified VRET Augmented With BF

Effect 1: Intrinsic Motivation

The average intrinsic motivation of the groups indicated better results for the BF group across all 4 mandatory games with 49 scores (the sum of motivation scores for BF vs non-BF in the first to fourth sessions were: 182 vs 174, 178 vs 169, 191 vs 160, and 182 vs 181). However, the results (*P* value [groups]=.15>.05=∝ and $F_{1,3}$=2.165) indicate no statistically significant difference. The analysis used a 2-factor ANOVA with replication.

On the basis of the results (*P* value [sessions]=.91>.05=∝; $F_{3,3}$=0.171), we can conclude that there were no significant differences in the effectiveness of the groups across the different sessions.

There were no significant differences in the interaction between groups and sessions (*P* value [interactions]=.61>.05=∝ and $F_{3,3}$=0.609).

Of the 5 participants in the non-BF group, 4 played 2 levels using BF. Two of them chose each game version, whereas the other 2 preferred the BF version exclusively.

Overall, BF had a greater effect on motivating patients. With greater efforts to leverage its potential within the game, the positive impact on motivation can be substantially enhanced. Nevertheless, it is essential to note that the non-BF version fosters motivation by incorporating 2 vital motivational elements: gamification and VR.

As participants enter new and especially challenging stages, their internal motivation to play tends to decrease, whereas their anxiety increases. However, with repeated attempts at this stage, motivation gradually increased, and anxiety levels tended to decrease.

Effect 2: Simulating Fearful Situations

The non-BF group had, on average, 40 points higher anxiety scores across all 4 rounds of the forced games compared with the BF group (the sum of anxiety scores for BF vs non-BF in the first to fourth sessions were: 11 vs 33, 22 vs 34, 29 vs 34, and 27 vs 28). There was a statistically significant difference between the 2 groups (*P*=.009<.05=∝ and $F_{1,3}$=7.805). The total anxiety score for the non-BF group was 129, whereas that for the other group was 89, indicating the beneficial role of BF in anxiety control. This finding also suggests that using BF could potentially reduce the need for a therapist's presence. Caution is advised when interpreting these data, as it may be influenced by individuals with severe phobias. The crucial point is that both game variants can evoke anxiety, as they simulate fearful situations. During the games, 5 participants (4 without BF and 1 with BF) experienced extreme stress, necessitating temporary pauses to help them calm down. One participant even reported an increase in blinking frequency when feeling nervous while playing the game.

The *P* value (sessions)=.32>.05=∝ and $F_{3,3}$=1.204, indicating no significant differences in the effectiveness of the groups across different sessions. Many participants experienced anxiety even before the games began, which significantly impacted their anxiety levels during training (picture step). One participant even mistook pictures of cats in the training as real cats because of high tension. In addition, 6 participants (4 without BF and 2 with BF) responded to the cat pictures. On the basis of the data and participant feedback, the order of increasing anxiety levels followed the sequence of stages, starting from the trial game and progressing through the forced games in the following order: fantasy, low-poly, and high-poly cats. Similarly, the normalization of cats occurred in the following order: fantasy cats, pictures of cats, low-poly cats, and high-poly cats. For instance, anxiety levels increased as the number of cats increased. No significant differences in interaction between groups and sessions were observed (*P* value [interactions]=.20>.05=∝ and $F_{3,3}$=1.652).

Effect 3: Controlling Stressful Circumstances, Eliminating Therapists' Presence, and Mitigating Catastrophic Thoughts

Most participants about the positive signs of reducing their catastrophic thoughts expressed that encountering cats had started to feel somewhat normal. They noted that with continued play, their irrational fears could be replaced with more rational ones, and these positive changes could extend beyond the game to real-life environments. One participant shared, "Before playing the game, I couldn't even look at cats' stickers or images, and I used to throw my toy cat out of my room window into the street." Another participant expressed, "Encountering fantasy cats in small numbers has become normal for me, and I believe that over time, my fear of other types of cats will decrease." Follow-up data are required to verify the lasting impact of these positive changes.

A total of six noteworthy comments on the elimination of therapists using BF were suggested: (1) after a few sessions, the game can be played independently without therapists; (2) the treatment process can be shortened; (3) patients with milder phobias can benefit from playing without therapists. Otherwise, therapists' support is necessary during the initial sessions; (4) the game is more beneficial for therapists, offering a controlled environment free of danger; (5) combining virtual and face-to-face treatments is recommended, starting with the game to prepare patients for real-life cat encounters; and (6) BF cannot provide the psychological support therapists offer. One participant, Fatemeh, repeatedly reassured herself during gameplay, saying, "Fatemeh, it's just a cat, it's nothing, keep calm." The necessity of a virtual therapist to provide reassurance and guidance during moments of severe anxiety was evident. Participants either managed to calm themselves or received assistance from us. At times, we had to explain the unlocked stage scenarios to convince the participants to proceed with the remaining games.

To enhance the effectiveness, some participants suggested that the game should display their effort by showing the minimum and maximum HR and the time taken to complete a level. In addition, 2 positive comments regarding HR were as follows: "I noticed that my fear is higher before encountering cats, but my heart rate decreases when I face them" and "Before playing, I believed my fear of cats was overwhelming, but the game helped me realize it wasn't as intense as I thought."

Effect 4: Preliminary Effects on Ailurophobia Treatment

Using ANOVA single factor, we could not detect a difference between the groups ($F_{1,8}$=0.073, and *P* value=.79>.05=∝). The S-scale scores worsened by 50 and 33 points in the non-BF and BF groups, respectively (Table 2). Both variants induced anxiety, but the BF group showed lower anxiety levels, suggesting that BF was more effective in reducing stress.

No significant difference between the groups was detected (*P* value=.63>.05=∝, and $F_{1,8}$=0.256). The non-BF group improved by 67 points in the FCQ scores, whereas the BF group worsened by 42 points (Table 3).

The significant difference in scores can be attributed to one participant in the non-BF group who initially experienced high anxiety before and during the game. However, as she played more games, her scores on the S-scale (64-28) and FCQ (119-13) decreased dramatically. She mentioned that she used to be greatly bothered by cats being near her or hearing their voices, but after playing the game, she felt less anxious. The constant presence of cats in the game and being able to hear their voices helped her overcome her fears. It is noteworthy that this participant played the game more than all other players, completing 10 levels, including the training stage. In the last 3 stages, the participants specified an anxiety level of 1 out of 10. Initially, we considered this participant's data as an outlier, but because of the high number of games played, we retained her data. This observation clearly indicates that playing the game more frequently helps to normalize interactions with cats. Her anxiety scores (of 10) for playing 9 levels of the game were (the data related to training was excluded for all participants): 10, 10, 8, 3, 3, 2, 1, 1, 1. By replacing her score with a typical number, we obtained more reasonable scores. The non-BF and BF scores worsened by 9 and 42, respectively. Both game versions induced similar anxiety levels in participants. Some of the participants experienced symptom improvement. To assess the initial positive signs of phobia treatment using the FCQ, we should wait until the completion of 10 game stages on average. All participants completed this questionnaire shortly after the games (within a maximum of 10 minutes), and the effects of anxiety caused by fear were still evident. We had to reassure them that the game was not very scary and that the unpredictable event they feared would not happen in the next level, as 4 participants experienced extreme anxiety. These participants took longer breaks between the phases or temporarily stopped playing the game. This anxiety could adversely affect their grades. In addition, approximately 80% (8/10) of the participants mentioned that playing the game more often helped them become accustomed to seeing cats.

All participants expressed a preference for the gamified VRET with BF, stating that the experience was more novel and perceived as more effective in reducing fear.

Table 2. Pretest and posttest scores of S-scales.

Groups	Pretest	Posttest	Difference
Non-BF[a] (control)	39	61	−22
Non-BF	64	28	36
Non-BF	38	67	−29

Patients' Preferences About the Designed Treatment

Most participants expressed that the game had a positive therapeutic impact and was capable of normalizing their interactions with cats. In total, 2 participants played the game 7 and 10 times and reported significant changes in their perception of cat-related fears. They shared that their perceptions of cat fear transformed, and encountering cats felt normal. Moreover, they believed that this effect could be extended to real-life situations. One participant shared, "I used to feel uneasy when cats were nearby, and the sound of cats was distressing for me. But now, as cats are consistently present in the game, and the sound of cats is played during the gameplay, being close to cats and hearing their sounds has become completely normal for me." In the last 2 stages, their anxiety levels were reduced to a rating of 1 of 10. Before playing, most participants anticipated that cats would appear in the forest and perch on the tree branches. They expected the paths where cats were located to have denser and more crowded areas, featuring an abundance of trees, wooden huts, and gazebos with cats nearby. One commented, "The space provided is too vast, and it could be made more intense to induce fear. It would be beneficial to create some narrower paths leading to a door where cats are positioned. This could instill more fear. Generally, the game's paths are not challenging situations, and a darker environment could make the cat's eyes more prominent." These comments contradict most participants, who appreciated the game's positive aspect of indirectly implementing treatment and displaying everyday interactions people have with cats. Incorporating various environments and cat behaviors could further normalize the interaction with cats from all angles. However, these changes must be introduced with caution to avoid reinforcing the perception that cats are scary. In addition, the suggested locations to be included in the game range from the park environment to urban settings, such as apartments, streets, alleys, markets, cafés, dark scenes, kitchens, and garbage cans.

Some participants preferred the fantasy cats, believing that they alone have the ability to normalize interactions with cats because they highlight the positive aspects of cats such as their beautiful eyes and portray them as attractive, safe, and less harmful. Designing different fantasy cats appears to be a reasonable way to encourage individuals. One participant said, "It bothers me that the cats' heads are small and their tails are long. In contrast, fantasy models had big heads and short tails. In different game levels, placing fantasy cats next to other cats conveys the feeling that all cats are harmless. Starting with images of rough and fat cats and gradually increasing the number of cats, and transitioning them to real models, helped me realize that the initial stage's image was merely in my mind and unreal. As the cats' numbers increased, I discovered that they did not pose any harm." These eye-opening opinions shed light on an overlooked aspect—the psychological impact of the game's difficulty levels and cat types.

Preferring fantasy cats indirectly revealed that low- and high-poly cats mostly evoke fear. Most participants found these cats to be more rational. Increased aversion and avoidance were observed in places with more cat voices and presence. Longer sounds also intensified fear.

On the basis of these findings, it is suggested to gradually introduce sounds, starting from cats with no sounds to short and pleasant sounds and then to real single and multiple sounds. The maximum fear was near the boxes where the number and noise of the cats were higher. Although this arrangement was found to be effective and logical in normalizing interactions with cats, high fear levels may have led some participants to avoid playing altogether. One participant preferred orderly and grouped cats for a calmer experience, whereas disorderly placement near the box increased fear. These reasons highlight the significance of using fantasy cats. Most participants found the size of the cats were found to be suitable. However, larger cat sizes, such as pictures of striped cats and low-poly cats, increased anxiety. The picture level, considered the easiest, induced anxiety and fear in most participants (6 of 10). Concerning cats' behavior, most preferred nonreactive cats, such as fantasy cats that simply look at the sky in a cartoony manner; cats sitting and grooming themselves; or cats moving along the path without any reaction. Most participants disliked black cats waving their hands or white cream cats turning and staring at the player.

Most participants expressed the need for the game's cat designs to closely resemble real-world cats. The following cats were not used based on their comments:

- Spotted (mainly black and white) and gray-striped cats, which are abundant in Iran.
- Kittens: Participants made three points: (1) kittens may not have a significant therapeutic effect, but they enhance the game's appeal and create a more lifelike environment; (2) the treasure finder can be replaced with a fantasy kitten, allowing for a more captivating display of less favored features of cats, such as their nails, tail, and head. Moreover, their beautiful eyes can be showcased as larger; and (3) the option of raising a kitten in the game.
- Fierce-looking cats with grabbing capabilities: adding them requires expert opinions. Although statistics on cat grabbing are limited, the actual occurrence is likely to be minimal. People's intense fears may exaggerate this concern.
- A mother cat breastfeeding her babies for a heartwarming and motherly touch.
- Sphynx cats: despite being rare in Iran, could enhance realism and normalize fear of diverse cat breeds.
- Fat or fluffy cats resembling a doll-like appearance.
- Placing cats amidst the greens and bushes along the paths.
- Injured (eg, cats with one eye or leg) or lifeless cats.
- Sudden movements of cats (eg, cats leaping out of trash cans): mentioned by most participants.
- Feeding cats: some participants did not agree with implementing this feature.

In conclusion, the game layout and models were considered logical by most of the participants. They stressed that fighting with cats in the game could worsen their fear, making a clear distinction between a therapeutic game and one designed solely for entertainment purposes. This opinion is in agreement with the clinical expert (the fourth author) who emphasized that the games for treating animal phobias should avoid action and fighting scenarios. For example, reducing the fear of cockroaches using scenarios where they stomp on or kill them may adversely affect.

Heuristics Evaluations

As presented in Tables 4-7, of the 44 heuristics adapted from the Nielsen user interface, VR, and playability, an impressive 41 principles obtained scores of 62% or higher, underscoring the tool's potential as a therapeutic product. Moreover, it enhances patient adherence to the treatment process.

Overall, 90% (9/10) of the participants found learning to play the game remarkably easy, particularly with the convenience of using just one button under VR glasses, which proved beneficial for those with mobility disabilities. Two suggestions emerged concerning in-game movement: (1) incorporating a back button and (2) movement through walking, potentially achieved with motion-sensing devices. However, careful consideration is necessary to ensure that they positively impact the player experience. Some individuals may prefer a less cumbersome setup. To enhance experience, it is crucial to incorporate a tutorial in a video or audio format for first-time users by introducing relaxation techniques to manage panic situations. Many participants required clarification that frightful situations would not occur at the subsequent levels. Providing detailed descriptions of new levels, including information about cats' types and behaviors, prevents players from creating self-made stories about cat attacks. Moreover, to improve clarity, players needed clearer instructions after opening each box, signaling that they should open 4 boxes per session. Although a ribbon in the corner of the screen displays the number of opened boxes, it does not adequately alert the players to this requirement. Among the VR principles, the navigation and orientation support principle excelled at 82%, with patients being well-informed about their in-game position. Notably, approximately 80% (8/10) of patients experienced no dizziness during extended gameplay. To increase the level of engagement and therapeutic impact, introducing a punishment mechanism, such as reducing players' points, could be beneficial. It might be worth reconsidering the features of allowing players to win the game without encountering cats. Game sounds and music received a relatively low score (51%), causing tension and unease, instead of promoting peace and happiness. The addition of soothing natural sounds was also suggested. In addition, consider a sound to indicate proximity to the box, reducing the need to check the bar constantly and improving the focus on gameplay. The game could benefit from a save and resume feature, especially during panic situations, allowing patients to take a moment to calm down. Some also raised concerns about the suitability of graphics for older adult audiences.

The principle of variety in the game's paths and challenges stands out as one of the main gameplay principles. Although it obtained a relatively good score (68%), most participants said that after a few stages, the game became monotonous. Players quickly realized that cats only appear in certain sections of the roads and near treasure boxes. Certain adjustments were recommended to enhance the game's appeal. Increasing the spacing between trees and raising their height can create a more immersive environment. Adding colorful elements such as flowers, toys, water views, and a gazebo in the park will infuse vibrancy into the game. In general, elevating the game's attractiveness can be achieved by introducing a greater sense of adventure without relying on unrealistic fears. One participant suggested that instead of having the treasure box as the game's goal, it could be placed in various locations within the forest, each rewarding the player with different prizes, such as food. Another suggestion was to replace the guide bar, which received positive feedback from the participants, with a map that indicated the approximate distance to the target. In addition, the introduction of a captivating and fantastical cat character instead of the current bar was recommended. In total, 2 participants pointed out that displaying HR in the corner might be somewhat distracting. It was suggested to show HR only when it was high or to remind players to reduce stress using a heartbeat's sound.

Table 4. Results of the questionnaire designed based on [49-51] for evaluating user interfaces and virtual reality apps, respectively (Tables S1-S4 of Multimedia Appendix 1 provides the noncompressed version of Tables 4-7 containing the list of questions).

Usability heuristic and question	Question, mean (SD)	Heuristic, mean (SD)	Heuristic overall percent, %

Table 5. Results of the questionnaire designed based on gameplay part of the playability heuristics [52].

Question	Question, mean (SD)	Heuristic, mean (SD)	Heuristic overall percent
1. Player's fatigue is minimized by varying activities and pacing during game play.			
Q1	3.4 (1.6)	3.4 (1.6)	68
2. Provide consistency between the game elements and the overarching setting and story to suspend disbelief.			
Q2	3.4 (1.3)	3.4 (1.3)	68
3. Provide clear goals, present overriding goal early as well as short-term goals throughout play.			
Q3	4.3 (1.1)	4.3 (1.1)	86
4. There is an interesting and absorbing tutorial that mimics game play.			
Q4	4.5 (1.0)	4.1 (0.57)	90
Q5	3.7 (0.9)	N/A[a]	N/A
5. The game is enjoyable to replay.			
Q6	3.5 (0.7)	3.5 (0.7)	70
6. Game play should be balanced with multiple ways to win.			
Q7	3.8 (1.0)	3.8 (1.0)	76
7. Player is taught skills early that you expect the players to use later, or right before the new skill is needed.			
Q8	3.4 (1.5)	3.4 (1.5)	68
8. Players discover the story as part of game play.			
Q9	4 (0.8)	4 (0.8)	80
9. The game is fun for the Player first, the designer second and the computer third. That is, if the nonexpert player's experience is not put first, excellent game mechanics and graphics programming triumphs are meaningless.			
Q10	3.9 (1.2)	3.9 (1.2)	78
10. Player should not experience being penalized repetitively for the same failure.			
Q11	4.3 (0.7)	4.3 (0.7)	86
11. Player's should perceive a sense of control and impact onto the game world. The game world reacts to the player and remembers their passage through it. Changes the player makes in the game world are persistent and noticeable if they back-track to where they have been before.			
Q12	4.1 (1.0)	3.9 (0.28)	82
Q13	3.7 (1.3)	N/A	N/A
12. The game should give rewards that immerse the player more deeply in the game by increasing their capabilities (power-up), and expanding their ability to customize.			
Q14	3.5 (1.3)	3.7 (0.28)	70
Q15	3.9 (1.0)	N/A	N/A
13. Pace the game to apply pressure but not frustrate the player. Vary the difficulty level so that the player has greater challenge as they develop mastery. Easy to learn, hard to master.			
Q16	3.9 (1.2)	3.75 (0.21)	78
Q17	3.6 (1.2)	N/A	N/A
14. Challenges are positive game experiences, rather than a negative experience (results in their wanting to play more, rather than quitting).			
Q18	3.8 (1.1)	3.8 (1.1)	76

[a]N/A: not applicable.

Table 6. Results of the questionnaire designed based on mechanic part of the playability heuristics [52].

Question	Question, mean (SD)	Heuristic, mean (SD)	Heuristic overall percent
1. Game should react in a consistent, challenging, and exciting way to the player's actions (eg, appropriate music with the action).			
Q1	2.8 (1.6)	2.8 (1.6)	51
2. Make effects of the AI[a] clearly visible to the player by ensuring they are consistent with the player's reasonable expectations of the AI actor.			
Q2	3.1 (0.9)	3.1 (0.9)	62.3
3. A player should always be able to identify their score/status and goal in the game.			
Q3	4.4 (0.5)	4.3 (0.14)	86
Q4	4.2 (0.9)	N/A[b]	N/A
4. Mechanics/controller actions have consistently mapped and learnable responses.			
Q5	4.4 (1.1)	4.15 (0.35)	83
Q6	3.9 (1.6)	N/A	N/A
5. Shorten the learning curve by following the trends set by the gaming industry to meet user's expectations.			
Q7	4.3 (1.3)	3.95 (0.49)	79
Q8	3.6 (1.6)	N/A	N/A
6. Controls should be intuitive, and mapped in a natural way; they should be customizable and default to industry standard settings.			
Q9	4.5 (1.0)	4.35 (0.21)	87
Q10	4.2 (0.9)	N/A	N/A
7. Player should be given controls that are basic enough to learn quickly yet expandable for advanced options.

Discussion

Principal Findings

We developed a gamified VRET augmented with BF to address ailurophobia. To our knowledge, no specialized research on ailurophobia treatment exists, either in Iran or internationally. Motivated by the high prevalence of ailurophobia and the lack of accessible gamified VR environments with BF, our main goal was to create and assess a smartphone-based VRET augmented with BF for animal phobia (cat phobia). We hypothesized that this tool would better motivate patients, manage stress, simulate fearful situations, treat phobia, and reduce therapists' involvement compared with a gamified VRET. The tool was designed based on expert sessions in video games, gamification, cognitive, and psychology. The results indicate its positive impact on specified features. Of the 44 heuristics, 41 scored above 62%, showing the potential for phobia interventions and motivating patients for treatment. Although tested on only 10 participants for a short duration (up to 3 hours without follow-up sessions), the results were reliable. Extensive data and feedback collection have been used to evaluate various aspects of the tool. On average, after 10 sessions, initial signs of improvement were observed, with slight variations depending on individuals' phobia levels. One intriguing finding was that most participants were content with the game's indirect approach to normalize interaction with cats and its nonviolent nature. They emphasized that action or combat scenarios would reinforce unrealistic fears and validate their phobia. Another significant finding was the progression of normalization in dealing with cats, tolerating their behavior, and hearing their voices, which gradually became more challenging. Although the current game normalizes communication with cats and holds good appeal, most participants suggested improvements, such as adding a variety of cats that closely resemble real-world characteristics, including voices and behaviors, to further enhance the normalization process. In addition, most participants expressed satisfaction with the game's easy movements and minimal learning curve. To enhance the experience, adding diversity and adventure while minimizing unrealistic violence was recommended. Moreover, during the evaluations, the participants strongly felt the need for a virtual therapist to provide calming guidance and support during moments of severe anxiety.

Comparison With Prior Work

To our knowledge, no study has simultaneously used BF, VR, and gamification for the treatment of animal phobia. However, various studies have used VR and game concepts to address specific animal phobias, for example, spider phobia [12,32] and snake phobia [47]. Similar to these studies, our tool successfully induced anxiety and led to a reduction in fear levels, avoidance behaviors, and catastrophic thoughts related to phobias. In addition, it positively boosted their motivation for treatment adherence. Unlike previous studies, our unique feature was the initial evaluation, showing that participants preferred a gamified VRET with BF. It has proven to be more effective in reducing symptoms and increasing internal motivation. These findings align with recent reviews highlighting the significant anxiety-reducing benefits of combining VR and BF, along with the advantages in motivation, user experience, involvement, and attentional focus [53,54]. In contrast to our study, where more participants preferred interacting with safe stimuli such as fantasy cats, studies such as those by Dibbets and Schruers [55] and Pittig et al [56] reported that selecting riskier options led to a stronger decrease in self-reported spider fear and disgust, whereas safe choices increased these emotions. The differing outcomes could be attributed to the use of VR and 3D images. VRETs are widely recognized as an appealing treatment modality because of their perceived naturalness in the automated format. However, Albakri et al [57] suggested that augmented reality exposure therapies offer a better experience and increased realism by seamlessly integrating digital information into the real world rather than creating a completely new virtual environment. We plan to explore the implementation of our designed tool with augmented reality and compare the outcomes in future studies. Dibbets and Schruers [55] found that the number of spiders encountered did not correlate with declines in aversive feelings and avoidance behaviors. However, our study concluded that a higher number of stimuli were more effective in normalizing interactions with cats. In addition, we observed that the action and combat scenarios were not beneficial for individuals with phobias. Interestingly, snake phobia treatment in a nearly action genre format [47] lacks a rationale for its selection. Further research is required to determine and devise appropriate scenarios for individuals with phobias. Throughout this study, the need to conduct similar research was highlighted. It was not feasible to make precise comparisons with prior studies in every detail.

Limitations

The initial study on treating ailurophobia using VRETs with gamification and BF had limitations, primarily a small number of respondents. A total of 10 potential participants were inaccessible after Instagram's temporary filtering in our country. The sample was skewed toward educated participants in their twenties and thirties, indicating the need to include diverse educational backgrounds, children, adolescents, and older adults. Owing to time constraints, we did not use any statistical method to calculate the required sample size. The study by Mor et al [48] recommended a minimum of 20 participants in each study arm for feasibility pilot studies on treating flying phobia using 360° images. Certainly, a larger number of patients is needed in each arm for the primary assessments. One future work is to replicate the study quantitatively and more rigorously while also introducing another arm that uses standard and clinical exposure therapies, enabling us to evaluate the tool and showcase more applications. In addition, the small sample sizes prohibited us from examining dropout rates. The results are exploratory, and long-term effects remain unknown due to the lack of follow-up data. Only one self-rating scale, the FCQ, has been used to diagnose individuals with ailurophobia. However, it is advisable to supplement such questionnaires with a telephone or face-to-face diagnostic interview conducted by an expert clinician, typically lasting approximately 30 minutes [2,12,32]. These interviews not only boost diagnostic reliability but also enable descriptive analysis [2]. It is worth mentioning that the patients were initially asked to explain the origin and signs of their ailurophobia. Participants were randomly divided into groups; however, the equality of their stress levels was not considered. It appears that by preserving randomness, the stress levels of individuals in the study groups should be nearly equal. For example, if one group has 2 extreme cases, the other groups should also have 2 similar cases to ensure transparency and enhance the reliability of the results. Creating a real-world game proved challenging owing to the limitations of the smartphone platform. Although playability and system usability questionnaires were not rigorously assessed, they were designed based on popular usability scales, including Nielsen [49,50], VR [51], and playability [52] heuristic evaluations. Changes in the individual's physiological status, particularly HR, influence their experience. Unfortunately, this feature could not be assessed in the BF arm owing to the small sample size. Understanding its effectiveness in high-tension situations and its role in reducing anxiety remains a top priority.

Conclusions and Future Work

The gamified VRET incorporating BF for treating cat phobia could be effective and has the potential to evolve into a comprehensive tool. One way to enhance its utility is by expanding the variety of cat types and behaviors, simulating different environments where cats are commonly found, and boosting its appeal through increased adventure while avoiding the use of unrealistic fears. After modifying the tool and using more robust study designs with ample sample sizes, further investigation can explore how this tool can be used in treatments without the presence of a therapist or combined (virtual and real simulation of fear), both in clinics and remotely. The park environment has the potential to effectively treat various animal phobias and other specific phobias. Implementing a gradual progression of sound stimuli could improve the therapeutic process. Starting with serene and pleasant sounds and gradually advancing to more challenging and potentially distressing voices, like cats squealing (inspired by a participant's recollection of hearing a cat giving birth) or their aggressive vocalizations during fights. The final suggestion is to add the possibility of interacting with cats during more challenging stages, thereby bridging the game environment with the real world.

Abstract

Background: The construction field is highly concerned with the risk of work-related accidents, and training employees is difficult due to their small numbers in most companies.

Objective: This study aimed to study the impact of a virtual reality (VR) training tool following a periodic occupational health medical visit on the feeling of personal effectiveness in preventing occupational risks related to co-activity on a construction site.

Methods: We conducted a cross-sectional study with employees who had a periodic medical visit between April 1, 2022, and October 13, 2022, in a French occupational health service specializing in the construction field (Services Médicaux Interentreprises Bâtiment Travaux Publics [SMIBTP]). The employees were divided into 2 groups according to the training received: a medical visit alone or coupled with a session with a VR tool. We compared the scores for a “feeling of self-efficacy in occupational risk prevention” using the Fisher exact test.

Results: Of the 588 employees included, 210 had a medical visit alone, and 378 had a medical visit coupled with VR training. Training with the VR tool was associated with an increased “feeling of self-efficacy in occupational risk prevention.” The employees who benefited from the training reported a willingness to apply the advice given on prevention to a greater extent than those who did not, and they believed that risks on the worksite could be reduced using this tool.

Conclusions: Using VR training as a complement to periodic medical visits in an occupational health service improves the feeling of personal effectiveness in occupational risk prevention at the end of the training. If this trend is confirmed over a longer period of time, it could be an easily accessible prevention lever for employees in the future.

KEYWORDS

virtual reality; virtual training tool; prevention; occupational medicine; construction

Introduction

Overview

The building and construction field is one of the most hazardous occupations in France. The main risks identified are the risk of road accidents, chemical risks, and musculoskeletal disorders, as well as risks related to the work environment and working with equipment. There are numerous work-related accidents, both fatal and nonfatal, with a major medicosocial impact on the individual and the community (long and costly medical care, prolonged absence from work negatively affecting the employer) [1]. In France, it is the leading field in terms of the frequency of work-related accidents, and the prevention of occupational risks remains difficult to achieve [2].

These difficulties are specifically related to collective prevention, which needs to be applied to a wide variety of tasks, sometimes in varying conditions and subject to change. Co-activities may be performed with employees from other companies in locations regularly situated very far from the company's head office. Small and medium-sized construction companies are the most affected by the lack of accessible risk prevention [3]. They also represent 99.8% of the companies and 45.7% of the jobs in France [4].

Health Monitoring of Employees in France

In France, all employees must undergo a periodic medical visit (at least every 5 years) in an occupational health services center. The main mission is to avoid any alteration in the employees' health due to their work. Thus, during these visits, employees receive advice to prevent occupational risks [5].

The Services Médicaux Interentreprises Bâtiment Travaux Publics (SMIBTP) is an occupational health service in charge of medical visits in the field of building and construction activity. In 2018, the SMIBTP monitored 2001 companies and 15,176 employees, mostly working in small and medium-sized companies. These companies work on a large number of sites throughout northern France. Since February 2022, the SMIBTP has been experimenting with a virtual reality (VR) training tool to train employees in the primary prevention of occupational risks related to co-activities on construction sites at one of its 2 consultation centers. The VR training is always preceded by a medical visit.

Virtual Reality

VR is a computer technology that involves real-time simulation and interaction through visual and auditory sensorial channels [6]. Computer-based 3D environments provide sensory information in a form similar to that received from the real world. VR allows individuals to experience and interact with or within environments with enhanced feedback [7-9]. To do this, users are required to be equipped with a VR headset that uses the principle of a stereoscopic 3D display connected to a computer interface to enable reproduction of the sensation of interaction with the artificial environment. The SMIBTP is the first occupational health service in France to have used a VR tool to provide additional prevention training for employees undergoing periodic medical visits. The goal of the SMIBTP is to provide employees with additional training in occupational risk prevention, with the aim of reducing the risk of accidents on site.

Objectives

No study has yet been conducted on periodic medical visits in an occupational health service coupled with a VR educational tool. A study in Finland compared VR with lecture-based safety training and found that the feeling of personal effectiveness in occupational risk prevention was increased by VR at the end of the training [10]. On a more general note, a review of the literature was carried out in 2023 on VR training and its impact on prevention, focusing in particular on the construction sector and its risks, highlighting that, although there appeared to be a positive impact, there was a lack of experimental studies in this field [11]. This was also highlighted in a meta-analysis published in 2023 [12]. However, it's important to keep in mind that these reviews pool together studies with different methods. Some studies are based on immersive technologies such as head-mounted displays, which rely on a computer connection [13], and mobile VR, which relies on the use of a smartphone [14]. Others have used less immersive techniques such as the Cave Automatic Virtual Environment, which involves virtual reality spaces where the walls, floor, and ceiling act as huge projection surfaces [15]. For the same method, the tools may vary (eg, headset brand), and above all, the context of the serious game may be very different (eg, risk prevention specific to certain trades vs risk prevention linked to co-activity on construction sites here).

The main objective of our study was to determine whether VR training had an impact on the feeling of self-efficacy in occupational risk prevention compared with a medical visit alone.

As a secondary objective, we wanted to know how the employees rated this additional VR training compared with the medical visit alone.

Methods

Design

This cross-sectional study included employees coming for a periodic medical visit to the SMIBTP who presented between April 1, 2022, and October 13, 2022, at one of the 2 centers.

The employees received 2 types of prevention training depending on the center in which they were examined. The employees in the first group had a medical visit coupled with VR (MV+VR group) training at the end of their periodic medical visit (Site A). The employees in the second group (Site B) had a medical visit alone (MV group).

Only employees performing manual work on construction sites were included in the study (engineers or secretaries were not included). In addition, in the VR group, only employees who completed the entire training (eg, no interruption due to motion sickness) were included.

The only exclusion criteria were an employee's past or present refusal of personal data collection and an insufficient knowledge of French.

Periodic Medical Visit

The role of occupational health services in France is to prevent any damage to workers' health caused by their work. The periodic medical visit is a preventive training tool used to this end. During these visits, workers can receive individual advice adapted to the workstation they occupy within their company. This involves oral advice, for example, on wearing personal protective equipment or using collective protective equipment. It may also, for example, involve a physical examination to assess the way employees bend over to pick up items from the floor. Finally, it may involve the delivery of paper documentation specific to the risks and workstations concerned.

Virtual Reality Tool

The VR training tool used by the SMIBTP is a serious game entitled SRC-Bâti VR (ViRtual Création), which aims to improve the occupational risk prevention skills of construction workers using VR digital simulation. SRC-Bâti VR emphasizes the co-activity aspect of construction sites and therefore the interaction between employees with very different workstations. Relative to a typical medical visit, it is less theoretical and more closely approaches real work, which is expected to have a positive impact in terms of prevention [16]. ViRtual Création was created in 2018 to develop software as an educational tool to improve worker safety.

The training sessions lasted between 7 minutes and 10 minutes, and a technician was present to equip the employee and explain how the device works. The training took place in a dedicated area of more than 10 m². The technician did not interfere during the training, except, for example, to prevent the employee from colliding with the equipment in the room.

During the training, the employees moved freely on a construction site. Workstations were clearly identified by markers. When the employee went to a workstation, a multiple choice question appeared about an accident risk at the workstation. If the employee did not answer correctly, the accident occurred, and a correction was provided. When an accident occurred, the employee's senses were stimulated to raise awareness of the risk. Workstations at which there was a risk of falling made a strong impression, as the impression of falling was real, as were situations in which there was a risk of being crushed. SRC-Bâti VR therefore offered a realistic simulation that served to teach skills in the prevention of occupational hazards linked to on-site co-activity. This realistic aspect gave a dimension of play to the VR simulation, with employees positively reacting to these virtual accidents, sometimes providing them with a simulation of what would happen (employees were never evaluated on their performance in the questions, which served only as an introductive teaching aid).

Depending on the employee's profession, 2 types of VR training were possible: one focused more on road work, and the other focused on building construction. Of the 20 possible workstations, 7 were randomly presented during the training, and 1 had to be present (possible workstations are shown in Table 1). No other customization was implemented in addition to the basic tool. Employees moved around the site by teleporting from one workstation to another over short distances, rather than gliding along, using joysticks. Although the training is short, the involvement of participants and interactivity and immersion offered by VR distinguish it from a simple paper questionnaire with the same questions (certainly greater involvement). The risks addressed were representative of the major risks on a construction site. Figure 1 illustrates how an employee is notified of a workstation, and an example of a workstation is shown in Figure 2. Figure 2 shows, on the left, the initial risky situation in which a truck backs up toward the employee in training and, on the right, the correction involves the employee moving away from the truck (green proposal). The red proposal indicates that the employee made the wrong choice before the correction and was run over by the truck. Demos can be viewed online [17]. The headset was a VIVE Focus 3 because, at the time the training was set up in 2021, it was the headset recommended by ViRtual Création and ViRtual Création was, at the time, the only French company identified by the SMIBTP that offered ready-made training material for building construction and road works. Since then, another solution dedicated to on-site risk prevention has appeared in France: VIRTUAL CONSTRUCT (Mimbus).

Table 1. Possible workstations depending on the training scenario in the Bâti VR serious game.

Scenario	Workstations common to both scenarios	Scenario-specific workstations
Road work	• Putting on personal protective equipment upon arrival on site[a] • Handling an unstable catwalk • Putting safety caps on the ends of iron bars • Waiting for trench walls to be reinforced to avoid being buried and limit machine traffic nearby • How to limit the risks associated with the vibrations from a jackhammer • How to deal with a truck backing up on a worksite • In front of an area cluttered with equipment, clearing a passageway without the possibility of falling objects before carrying out work in this space • In front of a colleague passing close to a load-lifting machine, informing the driver of the presence of the colleague to avoid any accidents • Using safety barriers when passing near holes in the ground	• Not driving past construction machinery but going around it by following the markings on studs • Using appropriate personal protective equipment when operating a circular saw • Using available handling equipment to carry loads instead of carrying them yourself • Replacing defective site signage • When laying asphalt on the road, wearing gloves, long sleeves, and pants for protection • Not working on a running construction machine engine • Using antipollution kits in the event of an accidental chemical spill on site • Bypassing work areas and following safe paths when moving around the site • When a construction machine reaches a buried network, stopping the machine and continuing work by hand • Warning a truck driver if he is going to hit a power cable when reversing • When climbing into a construction machine, always maintaining 3 points of support
Building construction	• Putting on personal protective equipment upon arrival on site[a] • Handling an unstable catwalk • Putting safety caps on the ends of iron bars • Waiting for trench walls to be reinforced to avoid being buried and limit machine traffic nearby • How to limit the risks associated with the vibrations from a jackhammer • How to deal with a truck backing up on a worksite • In front of an area cluttered with equipment, clearing a passageway without the possibility of falling objects before carrying out work in this space • In front of a colleague passing close to a load-lifting machine, informing the driver of the presence of the colleague to avoid any accidents • Using safety barriers when passing near holes in the ground	• How to avoid injury when carrying a heavy load • On scaffolding, limiting the risk of accidents by avoiding the presence of people working on several levels • Ventilating and vacuuming when using a sander • Before working on a pressurized water pipe, turning off the water supply completely • When using electrically-powered machines, never repairing the machine or its connections yourself • Using appropriate personal protective equipment when working near a colleague using a grinder • Disposing of rags soaked in chemical products after use • Reducing noise exposure by enclosing the compressor in dedicated rooms • Wearing appropriate gloves when welding • Alerting the colleague in charge of any abnormalities in load-bearing equipment • Using rolling scaffolding for occasional work at height

[a]Workstation mandatory for all training sessions.

Figure 1. Representation of a workstation accessible by the employee in the Bâti VR serious game.

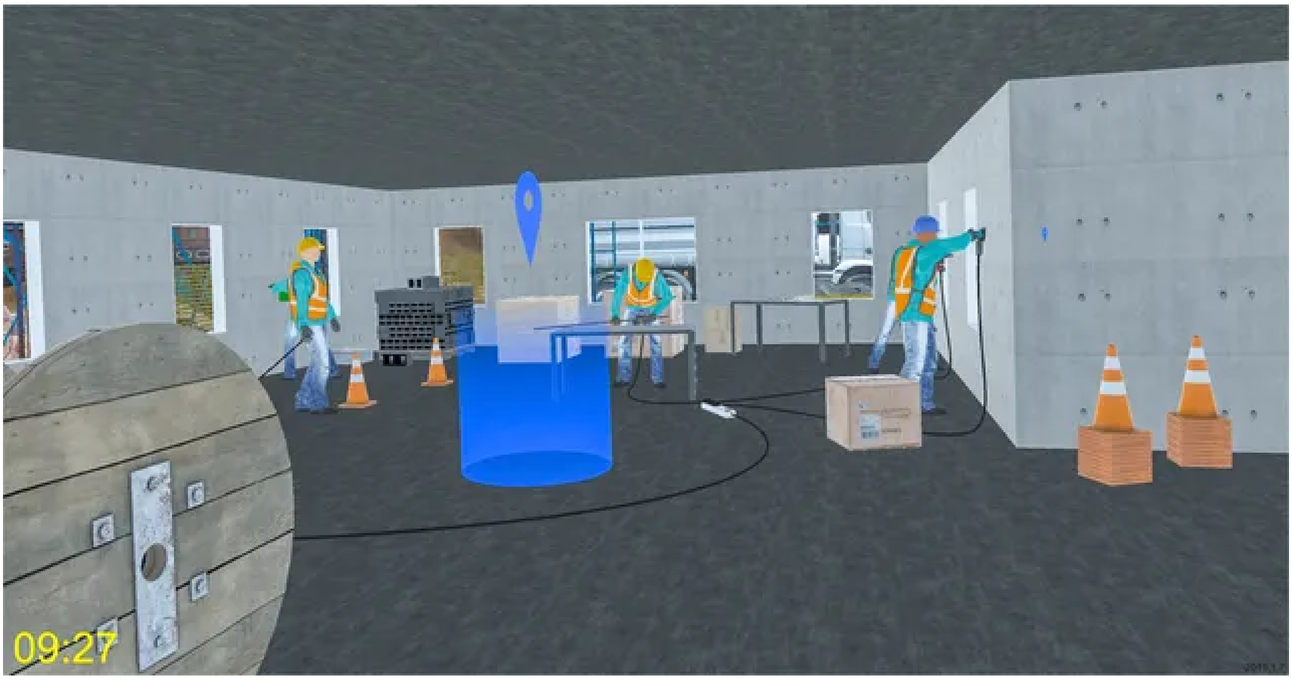

Figure 2. Example of a workstation in the Bâti VR serious game in which an employee is at risk of being run over by a truck.

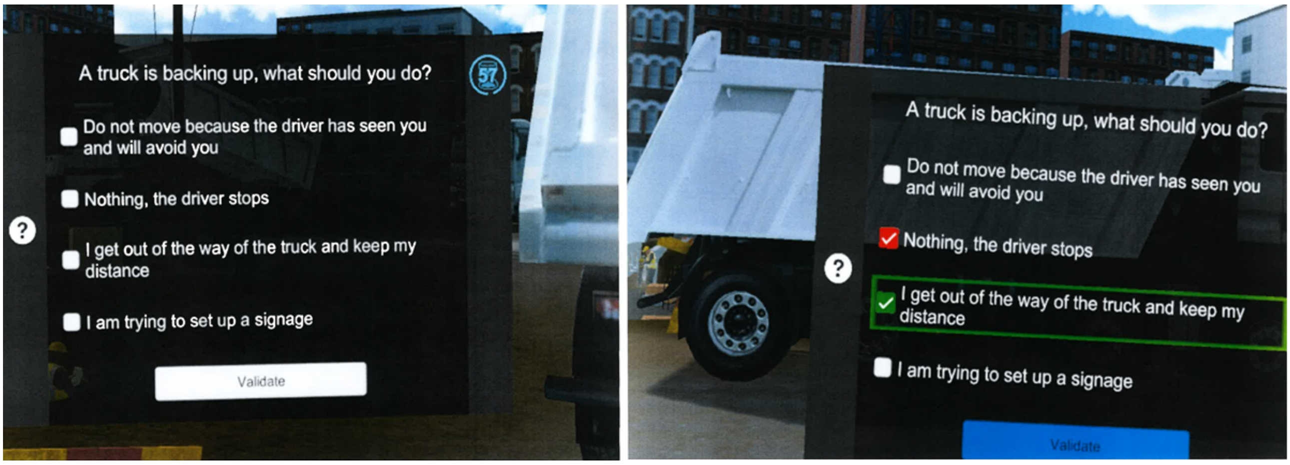

Ethical Considerations

As this was a cross-sectional study evaluating current practice in the use of virtual reality, it did not require review by an institutional review board. Virtual reality was used independently of the study, with only an anonymous virtual reality evaluation questionnaire added by our teams. The study was carried out in compliance with good data protection practice, with the agreement of the data protection officer of the Université de Picardie Jules Verne. Our study was not funded by ViRtual Création and we did not collaborate with the company in the conduct of the study.

Data Collection and Variables

We collected data using a questionnaire built using the LIMESUVEY tool provided by the University of Picardie Jules Verne. The questionnaire was completed directly following the intervention (site A) or after the medical visit (site B). The data collected were demographics (age, gender, size of the company in which the employee worked), type of medical visit (with or without VR), and questions related to the feeling of self-efficacy and their rating of the training using 5-point Likert scales. These questions have not been validated and were defined by the authors. The questionnaire we used, based on the LIMESUVEY tool, also did not undergo a prior validation study. It was, however, partially based on the model for self-efficacy questions by Kirkpatrick and Kirkpatrick [18], which is a training evaluation method based on 4 levels: reaction, learning, behavior, and results. It enables assessment of the effectiveness of a training program at different levels, from participant reactions to concrete results for the employer. This model is widely used in training and human resources development to measure the impact of training programs. We only studied reactions, as our study design did not allow for employees to be contacted at a later date. The immediate reaction was assessed by the statement “I feel more effective in prevention.” We wished to address the question of what employees felt they could apply in practice just after their training, in particular regarding on-site co-activity, using the following 2 statements: “I am ready to apply these prevention rules” and “I think that these prevention rules can reduce the risks with regard to other colleagues on the site." The other 2 questions were aimed at evaluating the training received in itself: "My visit to the SMIBTP was worth it" and "I learned about prevention."

To explore gender, we asked employees to indicate whether they defined themselves as male or female.

Statistical Analysis

Employees were divided into 2 groups based on the 2 types of prevention training (MV *vs* MV + VR). The primary endpoint was a difference (as a percentage) between the responses of the 2 groups for each item (on our Likert scale) on questions relating to "feelings of self-efficacy in the prevention of occupational risks." The secondary endpoint was the difference (as a percentage) between the responses of the 2 groups to questions relating to the rating of the training. Responses measured on the Likert scales were not transformed into a quantitative variable, to not distort the nature of this mode of questioning.

Baseline demographics and clinical characteristics are expressed as means (SDs) or medians (IQRs) for numerical variables and frequencies (percentages) for categorical variables. Between-group comparisons were performed using the Mann-Whitney *U* test (for age) and Fisher exact test for categorical variables (size of the company and gender). The chi-squared test could not be used because the number of participants for certain response modalities was <5. The Fisher exact test was used to assess the association between the type of prevention training and the primary and secondary endpoints. A *P* value of .05 was considered significant for all tests.

All statistical tests were performed using R software (version 4.0.0, R Core Team, R Foundation for Statistical Computing). The data and R scripts are available on MENDELEY [19].

Results

During the study period (April 1, 2022, to October 13, 2022), 588 employees were recruited.

The baseline participant characteristics by type of prevention training are summarized in Table 2. The study population was predominantly male (571/588, 97.1%). The mean age was 33.15 (SD 12.1) years. By comparison, in 2019, men represented 87.89% of employees in the construction industry in France, and the mean age was 42 years [20,21]. There was not a statistically significant difference between the 2 groups in terms of gender, but there were statistically significant differences for age and company size. Of the 588 employees, there were 210 employees (35.7%) who had the medical visit alone (MV group) and 378 employees (64.3%) who had the medical visit coupled with VR training (MV+VR group). There were no missing data.

The results for the "feeling of self-efficacy in occupational risk prevention" are shown in Table 3. The MV+VR group had a greater feeling of self-efficacy in prevention than the MV group. For each question, there was a statistically significant difference at the 5% risk level, indicating that the MV+VR group felt more effective in prevention in general and, more specifically, in co-activity on worksites and would be more inclined to apply the prevention rules learned during their visit to the occupational health service.

The results of the ratings of the interventions received by the 2 groups are shown in Table 4. Employees in the MV+VR group found the intervention to be more useful and to provide more knowledge in terms of prevention than those in the MV group.

Table 2. Study population characteristics by type of prevention training at the Services Médicaux Interentreprises Bâtiment Travaux Publics (SMIBTP).

Characteristic	Overall (n=588)	MV[a] (n=210)	MV+VR[b] (n=378)	*P* value
Age (years), median (IQR)	32 (23-42)	38 (28-47.75)	29 (21-37)	<.001
Male, n (%)	571 (97.1)	201 (95.7)	370 (97.8)	.19
Size of the company				.01
1-10 employees	214 (36.4)	60 (28.6)	154 (40.7)	
11-49 employees	224 (38.1)	91 (43.3)	133 (35.2)

Discussion

Principal Findings

The results of our study show that the use of a VR training tool at the end of periodic occupational medical visits had an impact on the feeling of self-efficacy in terms of occupational risk prevention in the construction field. This is an important finding, suggesting that the use of VR could have a significant impact on the occupational risk prevention practices of construction site employees. This is a useful finding, given that all employees in France systematically and regularly have such medical visits. Our results highlight a potentially important lever for the prevention of occupational risks in the construction field in the future through the improvement of employee competence.

Other Uses of Virtual Reality in the Health Field

Eiris et al [22] sought to validate safety training using 360-degree augmented reality panoramas. Their study showed the interest in the use of this method in the identification and recognition of hazards on construction sites. However, the rate of hazard identification was quite low, as only 30% of the hazards were identified by the participants. They explained this by the fact that their population was composed of students specializing in construction management (n=30) and were not building and construction professionals. They also emphasized the constructive comments concerning the ease of use of the platform, feedback that we also had in our study using VR. In our study, we did not analyze the responses to the questions asked during the VR training, as this did not correspond to our research question.

Nykänen et al [10] evaluated both the effectiveness of an immersive VR-based safety training program and a participatory human factors safety training program. The study was conducted with 119 employees working on 8 construction sites in Finland. The employees evaluated the training with questionnaires at the start, immediately after the intervention, and at a 1-month follow-up. They considered VR to be a serious tool for improving prevention skills and found that it motivated them to apply prevention rules more than after safety training based on passive learning methods. This study was conducted only with employees of medium-sized and large companies.

Simeonov et al [23] investigated the value of reducing mechanical vibration of support structures used as walking or working surfaces when performing construction tasks at height (falls from height account for one-third of fatal accidents in construction). Employees (n=12) used instrument-carrying gel insoles connected to a VR system to test sensory perception of the feet. The study did not show any effectiveness for this technology in 2008, but given the evolution of VR technologies, it is possible that the results would be different today.

We also found studies that assessed the use of VR as a prevention and training tool in fields other than construction.

The mining industry is a field in which the risk of serious accidents and fatalities is very high. Filigenzi et al [24] highlighted the value of using VR to train surface and underground mine employees and rescue personnel in hazard recognition and evacuation routes and procedures. This study, carried out in 2000, was innovative, demonstrated possibilities, and generated interest in extending such an approach to other fields of high-risk activity, such as construction, agriculture, and the oil industry.

In the logistics field, the use of handling equipment is responsible for a large number of occupational accidents, in particular to third parties. Choi et al [25] focused on forklift drivers, conducting a study with 20 students at Hong Kong Polytechnic University specializing in construction engineering. Their goal was to investigate how a forklift driver's situational awareness of others around him can be influenced by the type of subtasks he performs. A VR environment was used as the experimental environment in which participants performed a series of subtasks, such as driving, turning, reversing, loading, and unloading: the more concentration that was required for the tasks, the higher the risk of an accident. The authors concluded that it would be beneficial to not only use additional safety devices (such as person detection devices) but also have more detailed safety training, making VR meaningful.

In the area of electrical risk training, in 2015, Zhao and Lucas [26] reported that human error was responsible for approximately 50% of all electrical-related fatalities in multiple industries in the United States. They hypothesized that effective employee safety training programs, including VR, would be the most direct approach to mitigate such errors. Their study showed the success of using VR, highlighting training that effectively visualizes invisible risks without endangering employees. Such training increases awareness of the risk and trains employees to use the necessary protective equipment.

In the health care field, VR interventions appear to be an effective tool to boost the intention to be vaccinated [27-29].

The results of our study, as well as those of others in various fields, show that VR training tools hold great potential and should be further developed to improve the prevention of occupational risks, particularly in the construction field.

Strengths and Limitations

One of the strengths of our study is that it was conducted with a large population and 2 groups who were similar in terms of gender. In addition, the completion rate was 100% due to the use of a short and acceptable questionnaire.

However, the study population was mainly composed of men, which did not allow us to obtain data on the female population in the construction field. Women are not as well represented as men in the national population of construction employees. In addition, this intervention was intended only for certain construction jobs, mainly on construction sites, where women are much less present. The female population is mainly present in the administrative field of construction and public works companies and is therefore not subject to the same occupational risks.

Employees in the MV+VR group were younger than those in the MV group, which is similar to the overall population of construction employees in France. This result was expected, given the appetite of the younger generation for new technologies, such as VR. This age difference suggests that, if this tool is deployed on a larger scale, the older portion of the construction employee population might not benefit from it, as they may not want to use it.

The employees in the MV+VR group were also more often from small companies, which can be explained by the fact that they were the target population for the occupational health service. It is possible that this influenced our results, as larger companies have more resources for prevention. The employees of larger companies might therefore find this training less useful, but we believe that this does not affect the interpretation of our results.

It should also be noted that the use of VR is already a common practice in occupational health services and that our study did not change these practices, apart from the addition of the questionnaire. We therefore believe that our intervention did not bias our results.

On the other hand, we excluded individuals with the least mastery of the French language from our study. Individuals in this group are among those most at risk of having an accident at work due to the language barrier, in particular because of difficulties in understanding safety instructions. This does not call into question the validity of our results but highlights this group’s limited access to prevention through this tool. A translated version could be envisaged.

All the employees who participated were only seen once by the SMIBTP. It was therefore not possible to evaluate the impact of repeating these VR training sessions. Similarly, the design of the study did not allow an evaluation of the impact of this training at a later date. This was a major limitation of our study. Although these results are encouraging, other studies are needed to evaluate the long-term impact of VR training on the knowledge and perception of personal effectiveness in preventing occupational hazards. Longer-term studies are also needed to study the tool’s impact in terms of reducing the occurrence of occupational accidents.

In the context of our study, no data were collected that could be used to identify employees. Our objective was to reproduce, as closely as possible, the real-life conditions of using the tool, and we knew that collecting identification data could have significantly reduced participation in our study. If we were to carry out an evaluation at a later time point, it would logically be conducted under the normal conditions of periodic medical visits in occupational health services and therefore completed within 2 years to 5 years following our study. We would ask the employees coming for a visit whether they had already received training via VR. If so, we would request that they complete a questionnaire.

Further studies will be needed to assess the acceptability of VR. Indeed, one of the classic side effects of VR is motion sickness, and some VR sessions had to be interrupted because of symptoms such as nausea [30]. VR can also alter sensorimotor and perceptual abilities, with effects that can last several hours after exposure, and cause visual fatigue and headaches [31].

The routine use of VR during medical visits by occupational health services could have an impact on occupational risk prevention in the construction field. It could be a tool of major importance, given its accessibility, but its long-term impact and accessibility need to be assessed.

Acknowledgments

The authors would like to thank Ms Angélique Verzele, Dr Gérard Araszkiewirz, Dr Sébastien Amasse and the entire SMIBTP team for developing this virtual reality tool in their department.

Abstract

Background: In addition to illness, inactivity is a risk factor for high mortality in nursing homes. Using innovative technology, such as virtual reality (VR), for meaningful group activities could provide new opportunities for solving this problem. VR interventions have already been approved as a promising method for enhancing the health of older adults.

Objective: In this study, we examined whether VR-based group activities can have a positive impact on activity level and group interaction among older adults living in nursing homes.

Methods: We conducted a longitudinal study and provided VR interventions as a group activity once a week for 4 consecutive weeks in nursing homes. Participants were recruited based on the experience of the nursing staff members and the natural decisions of the older adults. Within a virtual cottage, designed according to the needs of the target group, older adults were able to perform daily tasks that they were no longer able to do in real life, such as gardening and making pizza. Overall, 2 psychologists measured the psychosocial capacities, activities of daily life, and well-being before and after the interventions using standardized instruments.

Results: The results focus on a total of 84 older adults from 14 nursing homes who completed at least 3 VR interventions. The results indicate that several psychosocial capacities among the older adults improved, including adherence to regulations ($P<.001$; $\eta^2=0.122$), flexibility ($P<.001$; $\eta^2=0.109$), and group integration ($P<.001$; $\eta^2=0.141$). Problems related to competence also showed a slight decrease ($P=.04$; $\eta^2=0.039$). In addition, the VR intervention promoted their proactivity ($P<.001$; $\eta^2=0.104$) and mobility ($P=.04$; $\eta^2=0.039$). During the VR group intervention, older adults' well-being could be maintained at a high level. The results highlight the beneficial effects of VR intervention as a meaningful activity in nursing homes, showcasing the potential of VR applications in this setting.

Conclusions: This study provides a novel and naturalistic perspective, offering new insights into the use of VR in nursing homes. The VR intervention was well accepted and fulfilled the aim of enhancing capacity and well-being. It could be a meaningful group activity in nursing homes to improve social group interaction. To provide stronger evidence, randomized controlled trials are necessary.

Introduction

Background

As a result of demographic changes and the development of physical and mental illnesses in the older adult population, residing in a nursing home for assisted living is a commonly chosen solution in later life. The perspectives of older adults residing in nursing homes are characterized by a prevailing sense of awaiting death and a dearth of activities that foster a sense of purpose and fulfillment [1]. Vossius et al [2] conducted a longitudinal study involving 690 older adults living in nursing homes over a span of 3 years. The median survival time in nursing homes was approximately 2.2 (95% CI 1.9-2.4) years. The annual mortality rate was approximately 30% [2,3].

On the one hand, the high mortality rate can be explained by the baseline health situation and comorbidity of the residents [3,4]. On the other hand, there is a loss of activities of daily living (ADLs). It is possible to reduce the risk of mortality by improving ADLs to maintain physical functioning [2]. ADLs encompass essential daily activities and mobility, such as eating and using the toilet. Ouden et al [5] observed a significant number of inactive older adults in nursing homes. Most of them were observed to be in a lying or sitting position [5]. A considerable proportion (67%) of the older population engaged in sedentary behavior for >8.5 hours per day [6]. This sedentary behavior and lack of communicative activity have critical implications for the prevention of physical, psychological, and social health problems [7]. This phenomenon also indicates social isolation and loneliness among older adults in nursing homes [8,9]. Older adults in nursing homes tend to be lonelier than community-dwelling older adults, even though they are often surrounded by other residents and caregivers [9-11]. Connecting with individuals with varying cognitive fitness levels is challenging in nursing home settings [10].

Several studies have been conducted regarding how loneliness and social isolation in nursing homes negatively affect mental and physical health, well-being, and mortality [12-15]. Studies have consistently shown that both loneliness and social isolation are associated with various mental health issues, including depression, feelings of hopelessness, and cognitive impairment [16,17]. Older adults residing in nursing homes experienced elevated levels of loneliness and anxiety during the COVID-19 pandemic compared to those receiving home care [18]. Overall, 69% of older individuals in nursing homes reported feelings of loneliness and 63% reported anxiety. On the other hand, among those receiving home care, 53% reported loneliness and 47% reported anxiety [18]. In addition, these conditions have been linked to impaired motor function, cardiovascular health problems, disrupted sleep, and increased frailty [13,19]. Zhao et al [20] found that higher engagement in activities was associated with lower levels of loneliness and frailty among older adults in nursing homes. The authors emphasized the importance of developing strategies to increase social and activity engagement in this population. Higher levels of activity engagement and meaningful relationships have been linked to greater satisfaction, well-being, and quality of life [15,21,22]. Therefore, there is a need to develop strategies that focus on improving ADLs, promoting engagement in activities, and enhancing social interactions among nursing home residents. These strategies have the potential to enhance overall well-being and quality of life and potentially reduce loneliness, social isolation, and mortality among older individuals residing in nursing homes [1,20,23].

Enhancing activity and social interaction among older adults can be effectively supported through meaningful daily group activities [24]. Participating in group activities fosters a sense of belonging, promotes social engagement, and contributes to overall well-being [24]. It provides opportunities for increased social interaction with fellow residents and emotional support through participating in games and identifying with teams [24]. It is also important that these activities are “meaningful” to the residents. Research by Tak et al [25] demonstrated that if activities are not relevant or meaningful to the residents, they may prefer to do nothing or passively watch television. Meaningful group activities are described as those that hold significance or provide enjoyment for individuals, aligning with their current and past interests, routines, habits, and roles and improving their mental or physical function [26-29]. It has been shown that meaningful activities enhance social engagement and well-being and reduce loneliness among older adults living in nursing homes [30]. Nevertheless, there are several barriers to providing meaningful group activities in nursing homes. One major challenge is the shortage of personnel. Nursing homes are already facing difficulties in filling nursing home positions due to a shortage of skilled workers [31], and this is expected to persist and worsen in the coming years. Insufficient staffing limits the capacity to organize several meaningful activities [32,33]. In addition, there may be constraints related to limited space and equipment within nursing homes [33]. Therefore, there is a need to develop new, low–resource dependent, easily applicable, meaningful group activities [34,35]. Moreover, the demands of older adults in need of care are evolving, including their expectations regarding the technical equipment in nursing homes. On the basis of a population survey conducted in Germany between 2009 and 2014, only a small percentage of older adults aged >65 years used smartphones, but by 2019, more than half of them were already using these devices. In addition, internet use has also experienced significant growth since 2009, with 74% of the older adult population using the internet in 2019 [35]. Therefore, introducing innovative, technology-based interventions such as virtual reality (VR) [36] for group activities could be a promising solution to improve social connections and activities for older adults in nursing homes [12,37,38].

Fully immersive VR has emerged as a feasible method of intervention in older adults’ rehabilitation and aging care [36,39]. By using head-mounted devices (HMDs) and controllers, VR technology provides users with a fully immersive experience and a sense of presence. The unique characteristics of VR offer a viable solution to the barriers faced in nursing homes [33]. These barriers include the health status of older adults, limited physical space in the environment, and organizational challenges such as staffing shortages and funding constraints. First, VR proves to be accessible and accommodating for older adults with limited mobility. For example, individuals can remain seated in a wheelchair while experiencing the sensation of being on a mountain surrounded by stars. This enables older adults to engage in activities that would otherwise be physically challenging or impossible. Moreover, VR interventions ensure safety as they eliminate environmental risks and can be paused at any moment, which is particularly important for populations considered vulnerable such as older adults [40]. Second, VR interventions are flexible and require minimal physical space, similar to the space requirements for small-group activities [41]. This flexibility empowers the staff members to efficiently organize activities, while also reducing the costs associated with transportation. Moreover, the effectiveness of VR interventions for older adults has been demonstrated. The immersive and presence-inducing nature of VR has shown evidence comparable to that of traditional interventions in mental health [42]. Using VR as a medium to improve ADLs for older adults has already shown promising effects [43], and it was found to be effective in reducing loneliness and social isolation [44-47]. In the field of mental health, VR is considered an effective method for training and therapy for cognitive functions and for enhancing the well-being of older adults [48-50]. In addition, several studies have reported high acceptance of VR experiences among older adults [39,51,52].

However, recent interventions have primarily focused on singular concepts such as training or entertainment, and there is a lack of studies exploring VR interventions as daily group events in nursing homes that provide opportunities for older adults to connect and interact socially. In this study, we developed and evaluated a series of VR interventions, aiming to enhance the overall health and well-being of older adults in nursing homes. The VR interventions combine training activities and entertainment to create meaningful group ADLs in nursing homes. As discussed previously, meaningful activities should align with older adults' current and past interests, routines, habits, and roles [28,29]. Studies have shown that older adults who engage in daily and household activities experience less decline in mobility [53]. For example, gardening has been recognized as a promising activity for reducing loneliness and improving socialization [54,55]. Building upon these findings, our VR group intervention focuses on providing older adults in nursing homes with virtual environments that allow them to engage in daily tasks they may no longer be able to perform, such as baking a pizza, handcrafting, and gardening. Through these simulated activities, older adults have the opportunity to experience the fulfillment of completing familiar tasks, while preserving and enhancing their physical and mental functioning. By using tasks that are familiar to them, we aimed to reduce fear or demotivation, which might occur when being confronted with new technology. The meaningful activities chosen for the VR game offer older adults an enjoyable experience and contribute to their overall well-being. Organizing these daily activities in a virtual environment incurs lower costs in terms of time and equipment compared to real-life implementation. In addition to the VR scenario, we developed an aid system and an automated program that enable staff members to easily facilitate VR group sessions with older adults.

In summary, this exploratory study investigated the effectiveness of implementing VR interventions as meaningful group activities for older adults in nursing homes. The primary focus was on evaluating the older adults' activity and mobility levels, well-being, social interaction, and mental capacities over the course of a 4-week VR group intervention. By supporting well-being and psychosocial capacities, these interventions have the potential to address key challenges faced by older adults in nursing homes.

Research Question and Hypotheses

This observational intervention study examines the following question: Does VR-based group activity have any positive impact on the daily lives of older adults living in nursing homes? The following hypotheses were tested:

- Hypothesis 1: Over the course of a 4-week VR intervention, psychosocial capacities and ADLs of older adults in nursing homes will remain stable or even improve.
- Hypothesis 2: Over the course of a 4-week VR intervention, older adults' well-being will remain stable or even improve.

Methods

Study Design

This longitudinal study using pre-post measures was conducted in naturalistic settings in nursing homes in a city with 250,000 inhabitants in Germany. After contacting all 31 local nursing homes, a total of 15 (48%) nursing homes chose to participate in the project.

Selection of Participants

We contacted all nursing homes by telephone. Subsequently, those nursing homes expressing interest were provided with a comprehensive briefing via email outlining the selection criteria. Participants were selected from the nurses in the nursing homes, who considered both the basic data (eg, medical history) about the older adults from the nursing home information system and their extensive experience in assisting older adults with their daily living, while also assessing the older adults' willingness to participate. The selection criteria were as follows: (1) older adults were aged >60 years; (2) they had at least 1 arm and 1 hand that they were able to use (this ensures their interaction with the virtual environment); (3) they were still able to see and hear, and the use of audio aids or glasses was permitted; (4) they were able to participate in an oral interview with the researchers and did not have severe dementia; and (5) they did not have diseases, such as epilepsy, that are contraindications for VR activities.

We set a control group that underwent the same measurement procedure as the intervention group, except that they did not undergo the VR intervention phase. The control group participants were chosen based on the advice from the nursing staff members. The older adults in the control group had a low willingness to participate in the VR intervention and expressed a preference for interviews. Of the 15 nursing homes, 1 (7%) chose to solely participate in the control group due to low willingness to organize new group events and expressed a preference for participating in the project only through interviews with older adults.

Procedure and Data Collection

The interventions were conducted for approximately 3 months in each participating nursing home. During this period, the intervention group went through 3 phases: premeasurement phase, 4 weeks of VR group intervention, and postmeasurement phase (Table 1). During the premeasurement phase, each older adult was offered an individual initial appointment. During this appointment, a psychologist explained the schedule, privacy agreement, and consent form to the older adult. One week after the initial appointment, the older adult underwent the first pretest interview (T0; baseline) with a psychologist. This baseline assessment covered mental capacity, ADLs, and well-being. In the following week, a brief, second pretest (T1) was conducted to familiarize the older adults with the well-being assessment. This served as a warm-up assessment and was repeated after each subsequent intervention session. The intervention phase began after the premeasurement phase. Group interventions were conducted every week for 4 weeks (T2-T5). These sessions were facilitated by a project psychologist and a technical assistant. Their role was to introduce the older adults to the VR program and provide support throughout the VR sessions. There were always 3 to 5 older adults in a group for an intervention. During each VR intervention session, the older adults were presented with tasks to solve in a virtual environment. After completing the tasks, the older adults participated in a 3-minute virtual tour of a landscape to relax. Following each VR group session, the older adults' individual well-being was assessed. One week after completing all 4 VR group interventions, the same psychologist who conducted the pretest interviews assessed the older adults' mental capacities, ADLs, and well-being in the posttest phase through a postintervention interview (T6). A follow-up interview (T7) with the same content was conducted 3 weeks after the posttest phase to assess the stability of the posttest results.

Table 1. Procedure of the virtual reality (VR) group intervention study in a nursing home (as per the focus of this paper)[a].

	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6	Week 7	Week 10

[a]Some procedures such as a questionnaire for feedback and obtaining perceptions from the older adults are not presented in this table.

[b]Mini-ICF-APP: Mini-ICF-Rating for Impairment in Psychological Activities and Capacities [56].

[c]ADL: activity of daily living [57].

[d]WHO-5: World Health Organization–Five Well-Being Index [58].

The study was conducted during the COVID-19 pandemic, and the safety of our older adult participants was our top priority. From our initial contact with the nursing homes, we inquired about and strictly adhered to the COVID-19 guidelines governing group events. Our team members underwent COVID-19 testing at public testing institutes within 24 hours before each visit to a nursing home. Even if a team member exhibited symptoms similar to those of COVID-19 but obtained a negative test result, they were not allowed to enter the nursing home as an extra precaution. During individual interviews, all team members wore masks, and regular hand disinfection was practiced throughout their stay in the nursing homes. During the VR interventions, we maintained a safe distance between the older adults, and the VR equipment was thoroughly disinfected after each use to ensure the highest level of safety for all participants.

VR Intervention and Equipment

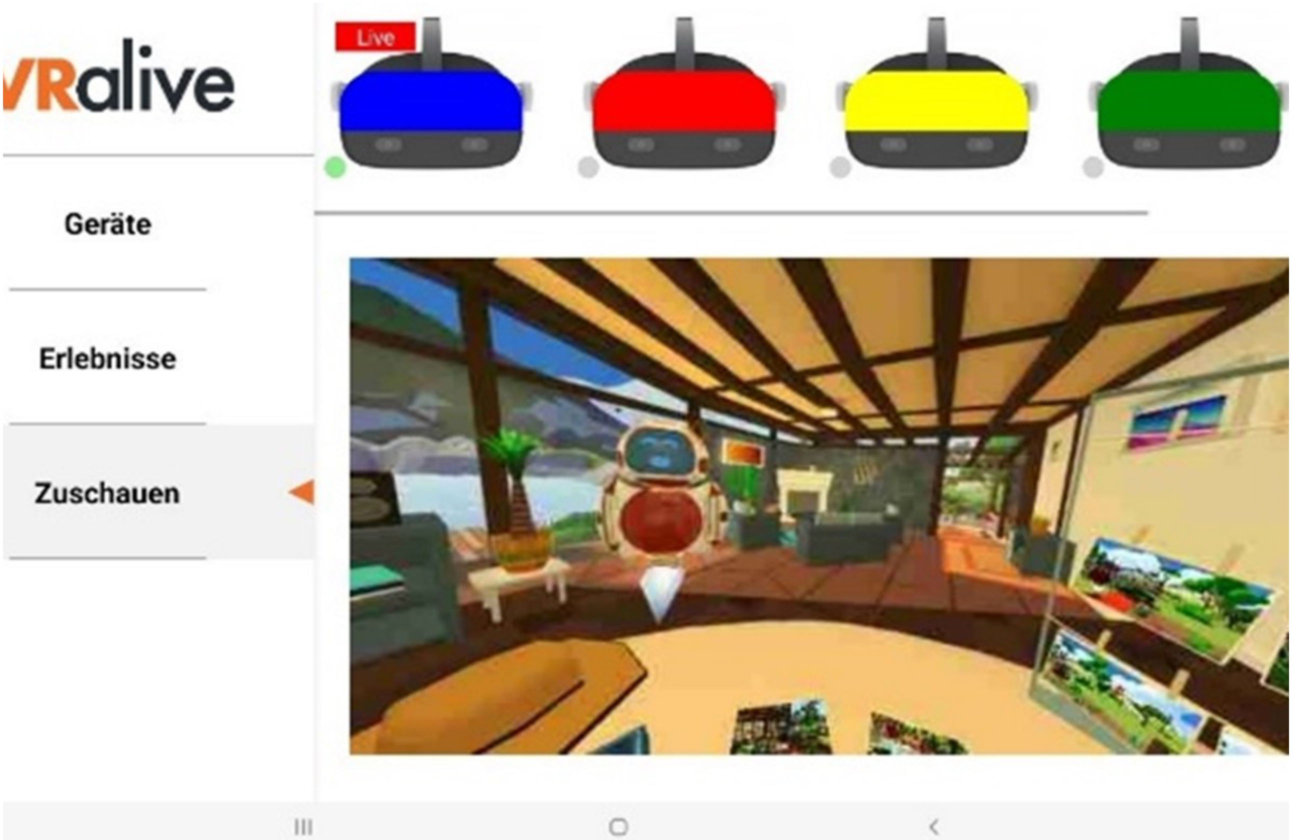
In collaboration with the technical company, VirtuaLounge, we developed a virtual vacation home to facilitate VR interventions for the older adults. We designed the meaningful VR activities in the virtual vacation home with an older adult–centered approach, drawing upon our understanding of older adults' daily routines and incorporating the valuable suggestions received from older adults during the pilot program testing phase while developing the VR intervention. The central aspect was to make the VR intervention as accessible as possible to the older adult population, while minimizing the barriers to use. For example, we ensured that older adults, including those using wheelchairs, could actively participate in the entire intervention by setting up the VR experience in a sitting format. We optimized the interaction with the VR environment to be easily manageable with only 1 finger, and all the tasks were designed to be completed using only 1 hand.

The interventions were conducted over a period of 4 weeks in regional nursing homes, with each session lasting approximately 30 minutes. Within each VR session, participants engaged in 4 or 5 tasks that were no longer possible for them to perform in real life. These tasks were integrated into a cohesive storyline, resulting in an immersive experience for the older adults. Our storyline revolved around 4 classic settings within a vacation home: living room, crafts station, garden, and kitchen (Figures 1 and 2). The tasks encompassed various routine activities, such as building furniture, gardening, and cooking in the kitchen. We devised a tablet control system specifically for those conducting the procedures to address the challenge of assisting older individuals wearing the nontransparent HMD. This system enables remote connectivity between the tablet and HMD. Through the tablet interface, a live view of the older adults' perspective is displayed, allowing the technical support personnel to monitor the progress of individual tasks for all participants. In addition, the tablet allows supporters to adjust the sound settings and remotely initiate or terminate the program on each HMD (Figure 3). This innovative solution enhances the ability to provide real-time assistance and control during the VR interventions.

Figure 1. Example task—gardening.

Figure 2. Example task—baking a pizza.

Figure 3. Screenshot of the tablet system.



The VR setup used in this study involved the use of the stand-alone VR Headset Pico Neo 3 Pro along with the Pico Neo 3 controller (Pico Technology Co, Ltd). The resolution of the VR headset was set at 1832 × 1920 per eye. The headset operated at a refresh rate of 72 Hz and featured 6 dfs inside-out tracking capabilities. In addition to the VR equipment, a Samsung Galaxy Tab S6 Lite (Samsung Electronics Co, Ltd) with an Android 12 operating system served as the remote tablet for the study. The system was programmed using .Net and C# programming languages.

Instruments

Consistent with our hypotheses, *psychosocial capacities* (hypothesis 1) included the mental capacities to adapt to daily life in a nursing home, which was assessed using the Mini-ICF-Rating for Impairment in Psychological Activities and Capacities (Mini-ICF-APP) scale [56]. This scale encompasses 13 psychosocial capacities, including proactivity and mobility. *ADLs* (hypothesis 1) included physical activity and mobility of the participants, which were assessed in more depth using the ADL-Barthel Index [57] that encompasses basic ADLs. *Well-being* (hypothesis 2) was measured using the World Health Organization–Five Well-Being Index (WHO-5) [58]. These measures were administered to both the intervention group and the control group, allowing for a comprehensive evaluation of the outcomes in both groups (Table 1).

The *Mini-ICF-APP capacity rating* [56] is an established instrument for describing a person's psychosocial capacity status. It has been translated internationally into many languages and is recommended in social medicine guidelines [59]. Among other settings, it is commonly used in settings of psychosocial rehabilitation. It is internationally recognized and has proven to be manageable, reliable, and valid in clinical practice [60-63]. In this study, the Mini-ICF-APP rating was designed to assess the psychosocial capacities for living in the nursing home, that is, performing certain basic activities on their own. The scale covers the following capacity dimensions: (1) adherence to regulations, (2) planning and structuring of tasks, (3) flexibility, (4) competence and knowledge application, (5) capacity to make decisions and judgments, (6) proactivity and spontaneous activities, (7) endurance, (8) self-assertiveness, (9) contact with others, (10) group integration, (11) intimate relationships, (12) self-care, and (13) mobility. Each dimension is rated using an 8-point rating scale (0=this is a strength of me to 7=this is impossible for me). The Mini-ICF-APP interview guide and questionnaire were adapted for the older adults by focusing on activities that individuals in need of care could still perform independently while residing in a nursing home. In a pilot study, 8 participants were interviewed by both project psychologists. Of the 2 psychologists, 1 conducted the interview, and both the interviewers completed Mini-ICF-PP rating sheet based on the responses provided by the older adults. On average, the interrater reliability over all 13 capacity dimensions was r=0.857. Psychosocial capacities were measured at 3 measurement time points (T0, T6, and T7).

ADL [57] was measured before the first VR intervention (T0), after the intervention (T6), and at a 3-week follow-up after the posttest phase (T7). It includes 10 dimensions of daily activity: (1) eating, (2) washing and showering, (3) body care, (4) dressing and undressing, (5) stool control, (6) urine control, (7) toilet use, (8) transfer from bed to chair, (9) movement and mobility, as well as (10) climbing stairs. The total score on the Activity of Daily Living-Barthel Index (ADL-BI) ranges from 0 to 100, with higher scores indicating greater independence in performing daily activities. A score of 0 indicates complete dependence on assistance for all activities, whereas a score of 100 indicates complete independence. An ADL score <80 indicates a need for care of >2 hours a day [64]. In the interview with the study participants, the psychologists asked about the activities one after the other and checked the plausibility of the answers of the older adults were. In cases of doubt, supplementary external judgments were obtained from the caregivers to ensure data validity.

The third instrument used in this study was the *WHO-5* [58], which is a concise self-report measure of current mental well-being. The assessment of well-being using the WHO-5 was conducted at baseline, after each VR intervention session, and during the postintervention and follow-up interviews. Numerous studies have demonstrated the validity of the WHO-5 as a screening tool for depressive mood and as a measure of treatment outcomes in clinical trials, and it has also shown good construct validity for assessing well-being in both younger and older populations [65,66]. The WHO-5 has been translated into >30 languages [66]. It consists of five statements that assess the individual's (1) good mood and cheerfulness, (2) relaxation, (3) activity and energy, (4) regenerative capacity through sleep, and (5) enthusiasm. Each statement is rated on a scale ranging from 1 ("at no time") to 5 ("all the time"). For example, 1 statement reads as follows: "Last week, I was happy and in a good mood." These statements are straightforward and nonintrusive in nature [66]. Typically, the questionnaire covers a 14-day period; however, considering the older adult participants and the study's weekly interventions, a 7-day period was deemed appropriate. Therefore, the assessment inquired about the individual's well-being, relaxation, activity level, quality of sleep, and interest in life over the past 7 days. Well-being was measured at each of the 8 measurement time points (T0-T7; Table 1).

Statistical Analyses

The data collected from the study were entered into the statistical software SPSS (IBM Corp) [67] for analysis. A repeated-measures ANOVA was conducted to analyze the data obtained from the 84 older adults in the intervention group who had participated in at least 3 interventions. The analysis focused on psychosocial capacities (Mini-ICF-APP), ADL, and well-being (WHO-5).

Owing to unequal sample sizes, a 2-factor, repeated-measures ANOVA between the intervention group and the control group could not be performed. However, the data from the control group (consisting of 11 participants) are presented descriptively, enabling a comparison with the values obtained from the intervention group.

Ethical Considerations

This study was funded by the German Federal Ministry of Education and Research (BMBF) (project number: 16SV8561 VRalive). This study was approved by the ethics committee of Technische Universität Braunschweig (FV-2020-18). Before the study, informed consent, confidentiality, and informed data protection were obtained from the participants or their life caregivers under the supervision of nursing staff. The older adults were informed of their ability to opt out at any time. The VR activities were provided as daily activities in the nursing home, and there was no compensation provided. All activities carried out in the nursing home were in strict compliance with the current nursing home COVID-19 prevention and treatment policy. For secondary analyses using existing data, we specified that the original consent approval covers secondary analysis without additional consent. The collected data were anonymized and deidentified.

Results

Participants and Demographic Information

A total of 116 older adults aged ≥60 years initially participated in the VR intervention group. Of these 116 participants, 31 (26.7%) discontinued their involvement in the VR group. The primary reasons cited for dropping out were concerns related to data protection and illness or death (Table 2).

Table 2. Reasons for dropping out (n=31).

Reasons	Values, n (%)
No more interest, without reasons	5 (16)
Several events are occurring	4 (13)
Incapable of participating due to illness or death	12 (39)
Virtual reality–related sickness (“cybersickness”)	5 (16)
No interest in interviews	1 (3)
Alternative events are preferred	2 (6)
Leaves retirement home	1 (3)
Cancellation of the group owing to very few participants	1 (3)

Sociodemographic information was collected at baseline and included older adults’ age, sex (male, female, or intersex), and educational and working history. The intervention group (N=116) had an average age of 80.74 (SD 8.49) years. The age range at the time of the intervention varied from 60 to 97 years. There was a higher proportion of female participants (81/116, 69.8%). Most participants (107/116, 92.2%) in the intervention group had no previous experience with VR. Table 3 presents more detailed demographic information.

We decided to consider only the data from older adults who participated in a minimum of 3 VR interventions to ensure that the analysis focused on the impact of the VR intervention. This resulted in a final sample size of 84 older adults to be analyzed statistically. Hence, for the purpose of this paper, statistical evaluation will be conducted on the data obtained from 84 older adults from the VR intervention group.

Furthermore, 12 older adults participated in the control group. One of the participants discontinued due to death (this has already been accounted for in the dropout statistics, as indicated in Table 2). The age range of the control group participants spanned from 61 to 94 years, with an average age of 83.75 (SD 8.97) years, and 10 (83%) of the 12 participants were women. It is important to note that the selection of participants for the control group was based on the perceptions of the nursing staff members and the natural decisions made by the older adults themselves. Consequently, the sample size of the control group in this study is notably small, rendering it insufficient for a robust comparison with the intervention group. Therefore, detailed information about the control group, which is presented alongside the intervention group data, is provided in Multimedia Appendices 1-3. The limitations associated with the small control group sample size are discussed further in the Strengths and Limitations section.

Table 3. Sociodemographic data about the older adults participating in the virtual reality (VR) intervention (N=116).

Features	Values
Age (y), mean (SD; range)	80.74 (8.49; 60-97)

Outcomes

Tables 4 and 5 present a summary of the results for the Mini-ICF-APP, ADL, and WHO-5 measures at specific measurement time points for both the intervention group and the control group. A macrolevel analysis indicates significant differences in the mean scores of Mini-ICF-APP ($P<.001$; $\eta^2=0.150$) and WHO-5 ($P=.04$; $\eta^2=0.032$) and the sum score of ADL ($P=.02$; $\eta^2=0.050$) within the intervention group.

Table 4. Comparison of the older adults' scores at baseline, at the end of the intervention, and 3 weeks after the postintervention assessment.

	Baseline (T0), mean (SD)	Postintervention assessment (T6), mean (SD)	Follow-up (T7), mean (SD)	rANOVA[a] (n=84)

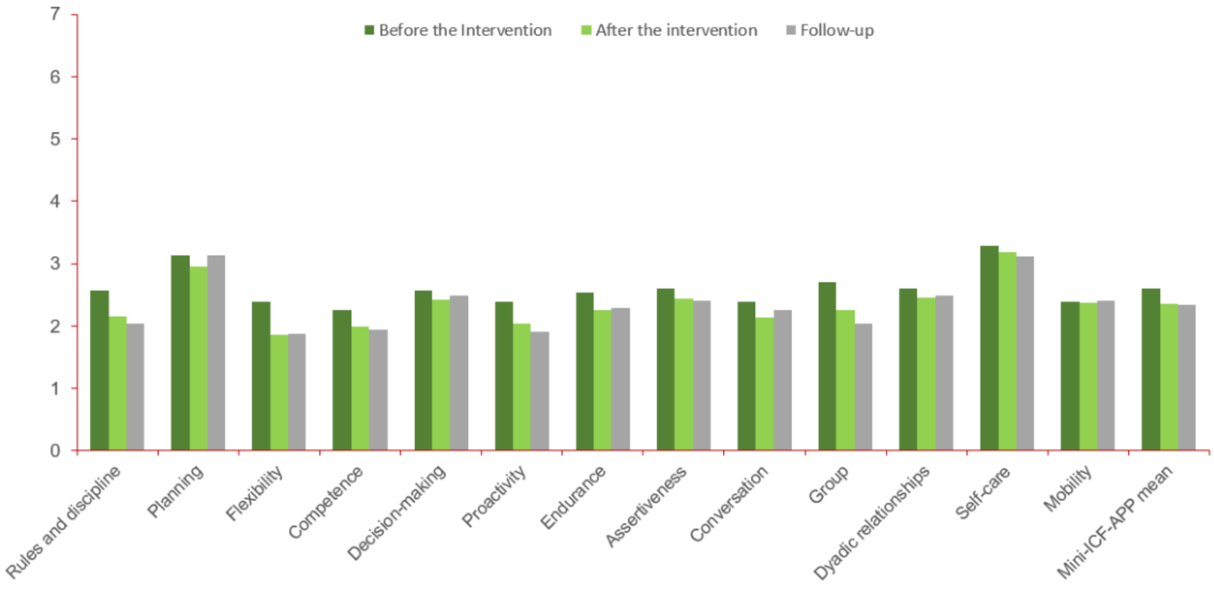
Specifically, the data from the Mini-ICF-APP indicated slight reductions in some psychosocial capacity impairments within the intervention group (Table 4 and Figure 4): adherence to regulations (*P*<.001; η²=0.122), flexibility (*P*<.001; η²=0.109), proactivity (*P*<.001; η²=0.104), and group integration ICF (*P*<.001; η²=0.141). Problems related to competence also showed a slight decrease (*P*=.04; η²=0.039).

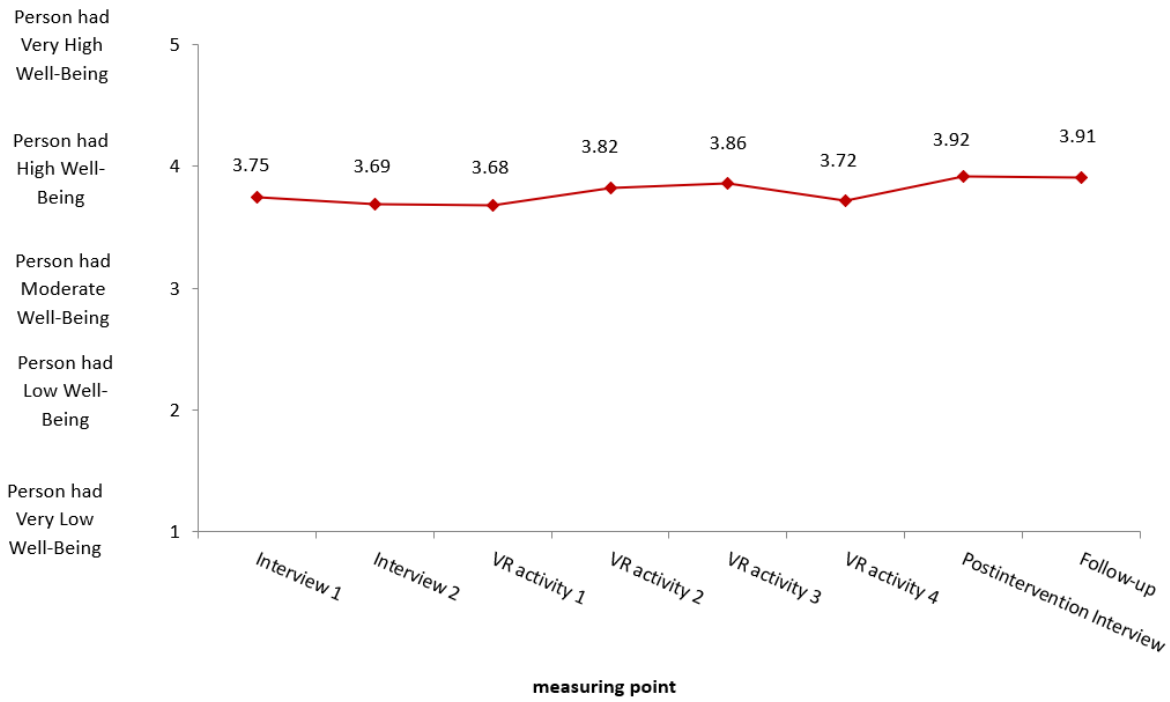
Figure 4. Changes in older adults' scores for the ability dimensions (Mini-ICF-Rating for Impairment in Psychological Activities and Capacities; Mini-ICF-APP) across the measurement time points: before the intervention, after the intervention, and follow-up during the intervention.. 0=This is clearly a strength of person, 1=Person is better than many others, 2=Person can do this well, 3=Person can somehow work with this, 4=Person does not always get this to work, 5=Person has problem with this, 6=Person needs help in this regard, and 7=Person is fully unfit.



Overall, 2 ADLs seemed to improve over the course of the VR intervention (Table 4): "Using the toilet" (*P*=.03; η²=0.040) and "mobility" (*P*=.04; η²=0.039).

In terms of well-being (WHO-5), 3 of 5 items in the WHO-5 showed significant changes (Table 5 and Figure 5): "feeling active" (*P*=.048; η²=0.029), "sleeping well" (*P*<.001; η²=0.054), and "being full of interest for life" (*P*<.001; η²=0.049). This indicates a slight variation in well-being over the course of the 4-week VR intervention period.

Figure 5. Mean of the World Health Organization–Five Well-Being Index for the intervention group at 8 weekly time points. VR: virtual reality.



Side Effects of VR

Throughout the VR intervention, there were no reported instances of older adults falling or accidentally colliding with nearby objects based on their sitting poses. In addition, there was no indication of potential interference with medical devices. While a few cases of cybersickness (5/31, 16%; Table 2) were reported, these were promptly addressed and resolved.

Discussion

Summary

The study aimed to determine whether a specifically designed VR intervention had a positive impact on nursing home inhabitants in terms of psychosocial capacities, activities, and well-being. In general, some dimensions of psychosocial capacities, activity, mobility, and well-being of older adults in the intervention group showed a slight positive improvement over the course of the intervention. Improvements were observed in adherence to regulations, flexibility, proactivity, competence, and group integration. The older adults showed improvement in their ability to use the toilet and physical mobility. The older adults reported feeling active, experiencing better sleep, and displaying greater interest in daily life.

Principal Findings and Comparison to Previous Studies

Psychosocial Capacities

The results of the study demonstrate an improvement substantially in the older adults' capacity to adhere to daily routines in the nursing home. This indicates that they have become more proficient in following schedules and maintaining self-discipline. In addition, the older adults show a greater willingness to adapt to and switch between different tasks or activities, both within the group setting and in public. Studies have shown that VR interventions can enhance the cognitive abilities of older adults, and these improvements are often correlated with their intrinsic motivation for training. This motivation can be triggered either by the engaging nature of the game itself or by the immersive experience facilitated by VR technology [68,69]. In addition, the study conducted by Fan et al [46] demonstrated that using VR as a form of entertainment for older adults can enhance their achievement motive and self-esteem, leading to improved mental health outcomes and reduced isolation, particularly among community-dwelling older adults. It is reasonable to assume that similar benefits could be experienced by older adults residing in nursing homes as well. In our case, the older adults' intrinsic motivation may stem from their own desire to participate in meaningful VR activities and engage with others, whereas extrinsic motivation could arise from the supportive environment provided by the staff members and the positive experiences associated with the VR group activity. The combination of intrinsic and extrinsic motivation appears to have contributed to the observed improvements in discipline and flexibility among the older adults; with these improvements, the older adult could fit better with daily life in the nursing home. However, it should be acknowledged that flexibility may also have been influenced by factors such as the visits from and relationship with the VR project psychologist. Over time, as the psychologist became more familiar with the older adults, they could have corrected any initial bias in the older adults' self-assessment, leading to more accurate evaluations based on their pragmatic experience.

The study findings indicate that the older adults' use and retention of competence and knowledge have improved. This outcome aligns with the study's design, which focused on implementing VR interventions with meaningful activities based on the older adults' familiar daily tasks. The positive impact of this approach is evident in the results obtained. The older adults were able to engage with the new VR activities, thus increasing their competence. Moreover, the result of improved capability of group integration indicated that after the VR intervention, the older adults gradually developed an interest in the group activity and expressed a desire to retry the task in the following week. A previous study by Padilha et al [70] found that VR offers a learning experience from interaction with the virtual environment and enhances knowledge acquisition in nursing education. It is plausible that VR can also be a promising tool for older adults to enhance these mental capabilities. Multiple studies have demonstrated that VR interventions have a positive impact on the memory and information-processing abilities of older adults [68,71,72]. VR video games could enhance the working memory and reasoning abilities of older adults [68]. The authors also suggested that VR interventions may improve problem-solving and planning skills, which are findings that align with those of our own study.

In summary, the VR group activity incorporating daily life tasks has shown to be a promising method for improving psychosocial capacities, including adherence to regulations, flexibility, and competence retention, among older adults in nursing homes.

Activity and Mobility

The results of the study demonstrate significant enhancement in the older adults' proactivity (Mini-ICF-APP). This suggests that the older adults experience less boredom and express a desire to engage in more daily activities that interest them while living in the nursing home. They are better prepared and motivated to initiate activities on their own. Furthermore, the ADL score, particularly in the mobility domain, also showed a significant improvement. This improvement in proactivity can be linked to the enhanced mobility observed in the ADL scale. The nursing home already provides gymnastic courses and physical therapy to help older adults maintain or rebuild their physical functioning. When older adults are more willing to participate in these activities, it can lead to better mobility and daily activity (eg, using the toilet) outcomes, aligning with the theoretical background that meaningful group activities can improve activity and mobility in nursing homes. Previous studies have investigated the impact of VR interventions on ADLs and instrumental ADLs among older adults, yielding different results. One of these studies aligns closely with our own study. Liao et al [47] conducted a VR cognitive training program that involved tasks such as locating stores and acting as a virtual kitchen chef, which is similar to our approach. Their results demonstrated a significant improvement in older adults' activity levels, with the effect size being larger than that observed with traditional cognitive training methods. Moreover, the improvement in the activity of older adults in nursing homes through VR intervention was also demonstrated by Saredakis et al [73]. In contrast, Optale et al [43] conducted a VR memory training program that consisted of repeated memory tasks focused on objects and orientation. Their study did not find a positive impact on ADL. This discrepancy suggests that the content of the VR intervention may play a crucial role in determining its effectiveness in enhancing older adults' daily activities. Overall, these findings highlight the importance of considering the specific content and nature of VR interventions when assessing their potential impact on the daily lives of older adults.

On the basis of the exploratory findings of this study, conducting an experimental study to provide evidence about the impact of VR interventions on proactivity and mobility would be valuable. Such a study can further validate the potential benefits of VR interventions in promoting proactivity and improving mobility among older adults in nursing homes.

Group Integration and Social Interaction

There was significant improvement in the group capacity of the older adults, indicating their increased willingness to participate in group activities and enjoy the benefits of group engagement. Thus, VR intervention could be used as a meaningful group activity that contributes to reducing social isolation. Staff members in some care homes also reported that older adults were pleasantly surprised by the VR technology and were more open to group activities after participating in the VR project. These findings are consistent with the results reported by Fan et al [46], who conducted a VR intervention involving horticultural group activities such as gardening for community-dwelling older adults, aiming to reduce social isolation. In addition, other previous studies involving VR horticultural activities in nursing homes have also demonstrated a reduction in older adults' loneliness and an improvement in their social interaction [44,74]. However, it is important to note that, unlike our study, these previous studies did not specifically focus on VR interventions as group events. Therefore, these studies have not reported about the impact of VR interventions specifically on group capacities of older adults. In addition to the VR horticultural activities implemented in nursing homes, the study by Saredakis et al [73] examined the effectiveness of VR reminiscence therapy in reducing older adults' loneliness but did not observe significant effects. This suggests that VR horticultural activities may hold greater potential in reducing loneliness among older adults. Engagement in meaningful activities, such as virtual gardening or horticultural group activities, might have a more profound impact on addressing the issue of loneliness in this population.

It is important to note that the project spanned periods of the COVID-19 pandemic and the winter and summer seasons, which could potentially act as confounding factors. While there was generally limited availability of group activities during the pandemic, the introduction of VR group sessions may have enhanced older adults' interest in social interaction.

Well-Being

Although there are statistically significant differences in the changes in well-being over the course of the intervention, it is important to note that the VR group activity has not yet demonstrated its full potential in consistently improving the well-being of older adults. The results indicate that there have been very small, incremental improvements in the well-being curve. The statistically significant difference observed may be attributed to the number of measurement points used in the study. We do not have a sufficient, practically relevant effect to confirm an increase in well-being.

The well-being of the older adults was already good at the beginning of the VR intervention study, which makes significant and consistent additional improvements less likely. Furthermore, well-being is influenced by various situational factors, particularly among older adults with health problems or disabilities considered vulnerable. Another factor to consider is the frequency and duration of the VR intervention, which may not have been sufficient to produce further improvement in well-being. Other VR studies that have demonstrated improvements in well-being often involve more frequent and longer VR interventions [44,50,74] or are only measured once after a 1-time intervention [48,75,76]. Furthermore, recent entertainment-oriented VR interventions targeting well-being or quality of life among older adults have predominantly used a passive interaction approach, for instance, virtual travel in Hong Kong [75]. These studies consistently achieved their research goals in terms of enhancing older adults' mood and well-being. In contrast, VR interventions that primarily focus on functional training with hand interaction have generally shown limited improvement in overall well-being, such as the one conducted by Brito et al [77]. The learning process associated with using the hand console can act as a barrier for older adults, potentially hindering their ability to improve their well-being through functional training. Consequently, it is crucial to approach the didactic process of VR devices with care to ensure that older adults are not discouraged at the initial stages of training. Furthermore, when developing VR interventions for older adults, it is important to consider the design and usability of the console or device being used. Older adults may have specific needs and challenges when it comes to interacting with technology. Therefore, the console or device should be tailored to accommodate their physical abilities, cognitive capabilities, and potential sensory impairments [78].

In summary, the well-being of older adults could be maintained at a high level over the course of the VR group intervention. It would be interesting to see if a more frequent intervention could further improve the impact of VR intervention on the well-being of older adults.

Strengths and Limitations

This study explored VR group activities in nursing homes, adopting a naturalistic approach to gain a deeper understanding of technology's role for older adults in the digital age. Our findings revealed the potential of VR as a tool in meaningful activity programs for older adults residing in nursing homes. Notably, this intervention leads to an enhancement in older adults' abilities and engagement in activities, while sustaining a high level of well-being. Our study offers novel insights into the transformative possibilities of VR for enriching the lives of older residents within nursing home settings. Despite the significant findings of this study, it is important to acknowledge several limitations.

First, the impact of the COVID-19 pandemic on the effectiveness of VR interventions cannot be ignored. During the pandemic, there were restricted group activities and increased vulnerability among older adults, which may have magnified the positive impacts of the VR group intervention. It is crucial to consider this unique context when interpreting the results.

Second, there may be a selection bias in the sample of participants. The selection of participants in the nursing home was based on defined and standardized selection criteria, which the nurses applied in the field. This is the most natural, accepted, and standardized way to select participants for psychosocial activities in nursing homes. There can be a slight selection bias due to the various individual interaction processes of the nurses with the participants. The selected sample may not accurately represent the range of responses in the population, but it represents older adults with complex disabilities who are nevertheless able to cope with specially designed VR tools. Moreover, recruitment was also based on older adults' willingness to participate in the study. The older adults who chose to participate in the study may be more open to new experiences compared to those who declined. Furthermore, the findings indicate that the older adults initially reported good well-being and had regular contact with family or friends, suggesting a limited scope for improvement in well-being and social interaction. It is essential to find ways to extend the reach of VR group interventions to a wider range of older adults, particularly those who are more isolated and lonely. Using a VR session to introduce the intervention to these older adults may be a potential solution.

Third, there is a possibility that the older adults may have overestimated or underestimated their own capacities. This could be addressed by staff members closely monitoring the older adults' daily behavior. However, due to limited personnel resources, this was not feasible in this study.

Finally, another weakness of this study is in its study design. This was not a randomized controlled trial. Although a control group was included, the sample size was very small, making it challenging to establish a valid comparison with the intervention group. Participation in the control group was based on the natural decisions of the older adults. Therefore, the results should be interpreted as a point of reference rather than indicative of a causal "effect." Nevertheless, it is important to note that this longitudinal study is naturalistic and externally valid. It offers a novel perspective on the pragmatic application of VR intervention as a group event in nursing homes.

Future Studies

On the basis of the findings of this exploratory study, a randomized controlled experimental trial that specifically focuses on VR group interventions within the daily lives of older adults in nursing homes should be conducted. Without the specific conditions during the COVID-19 pandemic, a more favorable social environment will be available, resulting in fewer hindering factors such as limited group interventions. In addition, in this study, large variation was observed in the basic cognitive functions of the participating older adults, according to age and type of disease. However, it is important for researchers to be mindful about the competencies and skill levels of older adults when introducing VR interventions [79]. Some older adults may feel socially excluded if they lack the necessary skills to participate in these digital activities [80]. Therefore, it is crucial to prioritize accessibility and provide adequate support and training to ensure inclusivity. This can involve tailoring the VR experiences to accommodate older adults with varying cognitive functioning, such as providing different levels of difficulty based on individual capabilities. In our study, we received diverse feedback from older adults regarding VR tasks. The highly independent older adults expressed that the VR tasks were very easy for them, whereas those with cognitive impairments or dementia found the tasks challenging to complete. In the next phase, it would be beneficial to group older adults based on their cognitive capacities and provide tailored VR interventions at different difficulty levels. Exploring an older adult–centered VR design is another intriguing direction for further investigation. This could involve studying the optimal form of interaction that minimizes the learning curve associated with using VR devices, ultimately enhancing the overall user experience for older adults.

Conclusions

In conclusion, the project successfully explored the benefits of a VR-based group intervention in nursing home settings. The results indicate that the VR intervention could be a meaningful group activity in nursing homes to support social group interaction, activity level, and well-being. The 4 sessions of the VR group intervention—with tasks that the older adults were unable to perform in their current environment— led to significant improvements in adherence to rules, flexibility, competence, proactivity, group integration, and mobility. Future research could benefit from conducting a randomized controlled trial to provide stronger evidence.

Acknowledgments

Funding for this project was provided by the German Federal Ministry of Education and Research (project number V5KMU1910044-02 EID 0017003). This study would not have been possible without the technical support of the VirtuaLounge team.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

BM and IS conceptualized the study and acquired the funding. BM designed the research question. IS and her team developed the virtual reality software. YL and CW conducted and implemented the study with technical support from IS in nursing homes. YL and CW collected and analyzed the data and prepared the tables for this paper. YL wrote the paper. BM supervised the research process and contributed to the writing and revision of the paper.

Conflicts of Interest

IS is the cofounder of the company, VirtuaLounge, which developed the virtual reality program used in this study. The developed program may be used commercially in the future.

Abstract

Background: Serious games, which are gaming applications used for purposes beyond entertainment to educate users on, and address, specific issues, may present a timely approach to promote healthy diabetes management behaviors among children with type 1 diabetes mellitus (T1DM). The lasting benefits associated with these serious games encompass improved patient education; enhanced glycemic control; the reinforcement of bonds within the community of people with diabetes; the facilitation of meaningful dialogues with caregivers, especially within the familial setting; and a significant reduction in the economic burdens associated with subsequent complications.

Objective: This paper primarily aims to provide a detailed overview of the iterative design process and the associated evaluation methods used in the development of the educational game. Furthermore, this study aims to enhance motivation for sustained and extended engagement with the game over time. The MyDiabetic game design aims to educate children on various aspects, including the connections among food, insulin, and physical activity. Furthermore, it seeks to impart knowledge related to the operation of a glucometer and an insulin pen, as well as more advanced technologies such as administering glucagon, measuring ketoacidosis, and continuous glucose monitoring.

Methods: The co-design methodology was applied, involving interviews, design workshops, and prototype feedback sessions. A combination of several approaches, such as tailoring, observational learning, social and family support, decision-making practice, and reward systems, was used to support children's compliance. Moreover, incorporating the literature, guidelines, and current practices into the design ensured that the game was aligned with established health care pathways and included relevant information and best practices for diabetes management.

Results: The game was tested on 32 children in 3 iterations. Positive responses were received from children who tested the game as well as their parents. The game was also presented to 5 schoolmates of children with T1DM who appreciated a better understanding of the disease and the opportunity to support their friends more efficiently in T1DM compensation. The involvement of children and clinicians in participatory co-design contributed to to the game's high acceptance. With regard to the game's impact on education, 1 week of testing revealed an enhancement in educational outcomes.

Conclusions: The game is especially suitable for children newly diagnosed with T1DM because it acquaints them in a fun way with new terminology; for example, they can try to measure glycemia levels in an interactive way. The game also caters to children who still need to develop reading skills by including an audio guide. The guide ensures that children of all literacy levels can benefit from the game's educational content and interactive experiences. The game is available for download on Google Play and the Apple App Store.

Introduction

Background

Type 1 diabetes mellitus (T1DM) is the most common form of diabetes in children. Poor blood glucose control increases the risk of chronic microvascular complications, including renal and retinal complications. When T1DM starts in childhood or young adulthood, the course of the disease is long, and metabolic control is essential to prevent such complications [1]. Advances in the treatment of T1DM have decreased the risk of complications and delayed their occurrence, with a resultant overall increase in the quality of life of patients. Nutritional education, with systematic assessments of carbohydrate intake and the use of the insulin-to-carbohydrate ratio, has allowed for optimizing insulin dosage [2]. The basal-bolus scheme with multiple-dose insulin injections, continuous subcutaneous insulin infusion, and multiple capillary blood glucose measurements allow for better metabolic control. For this, adequate and continued diabetes education for patients and families is required [3].

In general, mobile phones are a natural choice for use in increasing the efficiency of medical care and patient motivation [4,5]. The development of monitoring technologies and designing systems for improving diabetes mellitus compensation based on a mobile platform is increasing and widespread [6,7]. In the field of diabetes mellitus, there are already several pilot studies that validate the effectiveness of this new technology [1,8-10]. The biggest problem so far is the motivation of patients, as many stop cooperating after a few weeks or months. Furthermore, some authors state that the noncooperation of patients is one of the most common reasons why we encounter failure in education outcomes [4,11,12].

Well-designed serious games can improve children's learning, skills development, attitudes, emotions, motivation, and many other factors that encourage children to work together with family members and health professionals on treatment [13]. The long-term benefits of the serious game are improved patient education; better diabetes compensation; increased connections with the community of people with diabetes; stimulation of discussion with caregivers, especially within the family; and a significant reduction in the economic costs of subsequent complications. Furthermore, due to the widespread use of technology among children, using serious games to educate and support health behavior for children with diabetes self-management is an emerging and promising practice [14,15].

Some examples of previous approaches are Packy & Marlon (Super Nintendo) [16], Balance [17], Mario Brothers [18], Monster Manor (Nintendo) [19], and mySugr Junior [20]. Carb Counting with Lenny [21] is geared toward teaching users valuable information about healthy food choices and allowing them to apply that knowledge during gameplay. Jerry the Bear [22] seeks to educate children about T1DM by getting them to take care of the game's avatar, check the avatar's blood glucose level, manage insulin dosage by administering the doses using a pen or a pump, and feed the avatar with various food items. Except in the case of Jerry the Bear, the games show only the relationship among food, blood glucose level and physical activity. Some diabetes management games tested in small populations have never been brought to market and have no scalability. In addition, no studies were identified examining T1DM educational games' impact on user behavior, knowledge, or clinical indicators. Further research is needed to better understand the sustainability of T1DM gaming as a tool for promoting adherence and the effect of education.

Objectives

This paper primarily aims to provide a thorough overview of the iterative design process and the accompanying evaluation methods applied in the development of the educational game, MyDiabetic. Furthermore, this study aims to enhance motivation for sustained and prolonged engagement with the game.

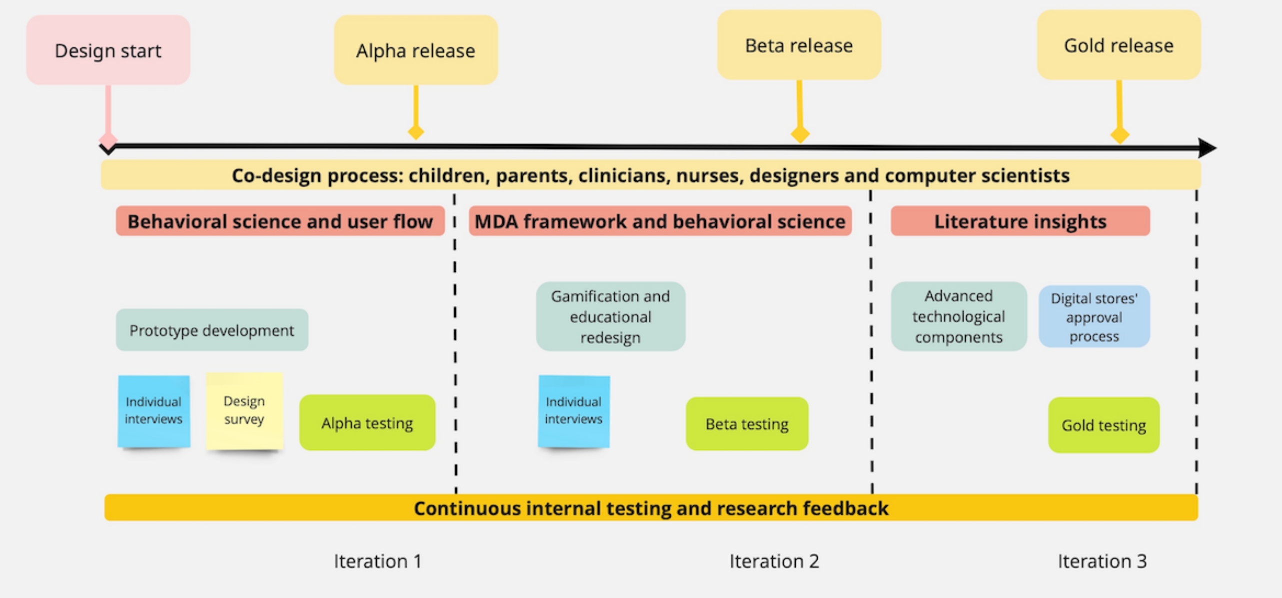
MyDiabetic aims to not only teach children the relationship among food, insulin, and physical activity but also pass on knowledge related to working with a glucometer and an insulin pen, as well as more advanced technology such as continuous glucose monitoring (CGM), insulin pump, glucagon administration, and ketones urine test. The game is designed for children aged between 5 and 12 years. It is especially suitable for children newly diagnosed with T1DM because it acquaints them in a fun way with new terminology; for example, they can try to measure glycemia levels in an interactive way.

Methods

Overview

A participatory iterative co-design approach was adopted. Participatory design in each iteration was guided by the fundamental principles from both traditional game design elements (eg, user flow and the mechanics, dynamics, and framework approach) and behavioral theory tailored for diabetes support. Figure 1 illustrates an approximate timeline for the MyDiabetic project, depicting key components of the participatory co-design methodology, along with the predominant principles used in each iteration indicated by the red bars.

Figure 1. Approximate timeline for the MyDiabetic project showing the principal elements of the participatory co-design methodology along with the predominant principles used in each iteration indicated by the red bars. MDA: mechanics, dynamics, and aesthetics.



Participatory Iterative Co-Design

The game was continually developed, resulting in the 3 iterations of the co-design phases applying participatory co-design principles. Figure 1 presents the timeline of the co-design process. Co-design process is intrinsically incorporated into the research. Co-design is a research methodology that actively engages diverse stakeholders to initiate, create, and validate solutions by adding creative and participative principles and tools [23]. Participatory co-design establishes that the necessary features of person-centered design, clinical acceptability, and health IT feasibility are accounted for, with each process needed for the ultimate success of the serious game. Table 1 describes user statistics during the co-design process.

The design team included several types of participants:

- Children in the user group and their parents, who were recruited through collaborating institutions, such as patient organizations, or Facebook groups
- Researchers with backgrounds in behavior change, informatics, and design
- Designers and developers (external and from the in-house IT system development group)
- Clinicians with vast expertise in T1DM management and nutrition nurses who are part of the project's advisory group

The first iteration of the MyDiabetic game was based on qualitative and quantitative research with children with T1DM diabetes, which led to the requirement for a game to help educate these children and help them cope with their new diagnosis. The outcome of the co-design research was the concept of continuous care of an avatar (based on the Tamagotchi principle) that is represented as a 3D avatar, including technical modules illustrating glucometer and insulin pen use. Subsequently, the co-design of the second iteration focused on incorporating educational material, such as an educational library and audio guidance provided by a physician's avatar, as well as developing other gamification features, such as game levels, minigames, and storyline extension. In addition, a model for measuring blood glucose levels was added. The third iteration addressed new technologies and methods, such as CGM and insulin pump modules, glucagon administration, and an explanation of ketoacidosis. Each iteration ended with usability testing. We followed software release cycle terminology. The alpha usability testing was focused on the evaluation of the main game concept, while the beta usability testing was the most detailed, concentrating on educational and adherence aspects. The gold usability testing evaluated new technological components only. The depiction of screens can be seen in Figure S1 in Multimedia Appendix 1.

Detailed information regarding the characteristics of the children for each iteration can be found in Tables S1-S6, S9-S10, and S12-S13 in Multimedia Appendix 2.

The clinical team was composed of experts who possessed diverse experience in various aspects of T1DM. Throughout the development process, these clinicians consistently provided invaluable feedback during presentation workshops conducted at the conclusion of each iteration.

Table 1. Description of iterative design and user statistics.

Iteration and activity	Users	Age (years), mean (SD)	T1DM[a] duration (years), mean (SD)	Stage of development	Features introduced
Iteration 1					Basic gaming concept, design of control elements, taking care of the avatar concept, carbohydrate counting, insulin pen administration, measurement of glycemia level, and performing exercise
Interviews	Boys: 4; girls: 0	12.8 (1.3)	5.5 (2.6)	Mock-up	
Design survey	Boys: 15; girls: 12	10.2 (2.1)	4.8 (3.0)	Mock-up	
Alpha testing	Boys: 8; girls: 4[b]	10.5 (2.7)	3.7 (2.2)	Alpha release	
Iteration 2					Education elements, such as an educational library or simulations of blood glucose, minigames, storyline, and levels design
Beta testing	Boys: 2; girls: 4	9.6 (4.5)	4.8 (2.9)	Beta release	
Iteration 3					Advanced topics such as CGM[c] and insulin pump illustration, measurement of ketoacidosis, and glucagon administration
CGM testing	Boys: 7; girls: 2	12.8 (1.7)	7.0 (3.7)	Gold release	
Glucagon testing	Boys: 4; girls: 4	13.2 (2.6)	6.4 (1.8)	Gold release	
Keto-acidosis testing	Boys: 2; girls: 5	12.2 (2.7)	8.9 (3.2)	Gold release	

[a]T1DM: type 1 diabetes mellitus.

[b]Of the 12 users, 5 (42%; n=2, 40% boys and n=3, 60% girls) did not have diabetes.

[c]CGM: continuous glucose monitoring.

Serious Games and Behavioral Theory Foundations

Methodological aspects of user flow [24]; the mechanics, dynamics, and aesthetics framework [25]; and behavioral theory (tailoring [26,27], observational learning [27-29], decision-making practice [13], social and family support [30,31], and reward systems [27,32]) were used during the design of MyDiabetic. Theoretical backgrounds are summarized in the Theoretical Background and Game Design section in Multimedia Appendix 1.

On the basis of literature research, guidelines, and current practices [13,19,21,22,33], the characteristics that are important for a successful serious game were further identified (Textbox 1).

Textbox 1. Characteristics that are important for a successful serious game.

Important characteristics

1. The main avatar should be empathetically connected to the player. One possibility is to use avatars that reflect the player in the game [34]. Customizing the avatar in game should also be possible (refer to the Avatar Tailoring subsection under Theoretical Background and Game Design and Figure S2A in Multimedia Appendix 1).
2. The game should have an incentive and customizable reward system that supports the player’s learning. As a reward, the game can offer trophies or new *unlocked* game content (refer to the Level Progress Design subsection under Theoretical Background and Game Design and Figure S2B in Multimedia Appendix 1).
3. The game should aim to develop the player’s skills by setting clear but challenging goals related to changing the player’s behavior in real life (mainly all educational and technical features developed in iterations 1-3: iteration 1 [main game concept], iteration 2 [educational and gamification features], and iteration 3 [advanced features]).
4. The difficulty should gradually increase and adapt to gradually improving the player’s skills, giving the player further opportunities for improvement (refer to the Level Progress Design subsection under Theoretical Background and Game Design in Multimedia Appendix 1).
5. The game should have a realistic and health-related story. This attractive design includes high-quality graphics, sounds, and animations to immerse the player in the game (refer to the Scenes Description subsection under Theoretical Background and Game Design and Figure S1 in Multimedia Appendix 1).

A summary of the game and the methodology is provided in Multimedia Appendix 3. In addition, Multimedia Appendix 4 contains a video highlighting the game's main features.

Participant Recruitment

The whole concept was iteratively validated throughout the 3-stage iteration design process. Children were recruited through the project website [35], at diabetes summer camps, and via Facebook groups and through nonprofit organizations dealing with treatment support. The eligibility requirements were as follows: (1) fluency in Czech, (2) possession of a smartphone for a minimum of 2 weeks, (3) a confirmed diagnosis of T1DM for at least 1 year, and (4) aged between 5 and 16 years.

Ethical Considerations

The design process was approved by the committee for research ethics at the Czech Technical University in Prague, Czech Republic (0000-01/24/51902/EKČVUT). Written study information was provided, and written informed consent was obtained from parents. All users agreed to provide anonymized data for research and data analysis during the sign-up process, which was required for app use.

Development Approach

Agile principles [36] were used for the rapid development of various components and for iteratively integrating. Undergraduate and graduate students (computer science and biomedical engineering students) participated in developing new functionalities over 8 semesters. The game was prereleased on Google Play at the end of each iteration design process for feasibility testing. User feedback and bug fixes were communicated in weekly core team meetings and daily written discussions (via email and Slack). During the academic term, student meetings were also held once a week. A cross-platform solution, Unity software (Unity Technologies) [37], was used for game development; a free and open-source platform, Blender, was used for 3D modeling [38]; the GitHub tool [39] was used for versioning; and the Trello project management tool (Atlassian) [40] was used to track bugs and for project management. Furthermore, each task was developed in a separate branch on GitHub before being tested and approved by another team member and then merged into the master branch.

Results

Herein are presented the results of the design and development phase that gave rise to the MyDiabetic game as a person-centered education tool, along with details of the contributions provided by each iteration of the participatory co-design methodology.

Iteration 1: The Main Game Concept

Overview

In the first phase, the main game framework was outlined, focusing on carbohydrate counting and elementary technological tools for the measurement of glycemia levels and insulin administration. In addition, the basic gamification concept was proposed. The main aim of the usability study was the determination of user experience.

Individual Interviews and Design Survey

The co-design methodology was applied throughout the whole game design process. The main gaming concept was built in the first co-design iteration. First, qualitative (individual interviews) and quantitative research (design survey) methods were used to collect game design requirements. The additional documents for interviews are described in Multimedia Appendix 1 (refer to the Screener, Session Guide, and Design Survey subsections under Alpha Release). In addition, research was performed among parents, who are very important stakeholders in T1DM management. The questionnaire for parents is presented in the Questionnaire for Parents subsection under Alpha Release in Multimedia Appendix 1; a summary is presented in Table S1 in Multimedia Appendix 2.

User needs were specified, for which an informal interview was conducted. Four users with T1DM were invited to the interviews. Two observers were present during the interviews. One observer moderated the session, while another took notes, kept track of the time, and made observations. This was followed by rapid prototyping using the user-centered design methodology. The prototype used the basic paradigm mentioned in the Theoretical Background and Game Design section in Multimedia Appendix 1. The summary of the interviews is presented in Table S2 in Multimedia Appendix 2.

Parents play a big role in diabetes compensation. In this study, in children diagnosed at a young age, parents took care of insulin administration, the measurement of blood glucose levels, meal preparation, and writing in the diabetes diary. Parents would check their children regularly, some excessively, especially if they were physicians themselves. All participants used paper diabetes diaries because it was almost always the participants' mothers who took up the responsibility of maintaining the diaries, and they did not seem to be very confident about using mobile app technology (if the children were to enroll, they would have preferred to use a mobile app). The children learned about managing the disease by observing their parents' actions. Initially, when they were at school, they had to call their parents, who told them the appropriate insulin dose to inject. In time, the children became confident, and consulting their parents was no longer necessary. Quantitative research was carried out at diabetes summer camps (refer to the Design Survey subsection under Alpha Release in Multimedia Appendix 1 as well as Table S3 in Multimedia Appendix 2). In total, 27 questionnaires were collected among children aged 7 to 13 years. The main interest centered around where children obtained most of their information about diabetes and if they had ever encountered a game about diabetes. Other topics of interest were current favorite games among the children and how independent the children were in terms of counting bread units (BUs) and insulin administration.

On the basis of the results (refer to Tables S1-S3 in Multimedia Appendix 2), the main requirements for the game can be summarized as follows:

- Teaching the relationship among food, insulin, and physical activity to children with diabetes
- Teaching children with diabetes how to count bread exchange units
- Demonstrating the symptoms of hypoglycemia and hyperglycemia and their solutions
- Demonstrating insulin administration, including technical skills and dose adjustment, and explaining how to assess diabetes compensation by blood testing
- Explaining the nature of the disease
- Motivating children to exercise
- Being available free of charge and to as many people as possible
- Being both educational and fun so that children can continue playing it for as long as possible

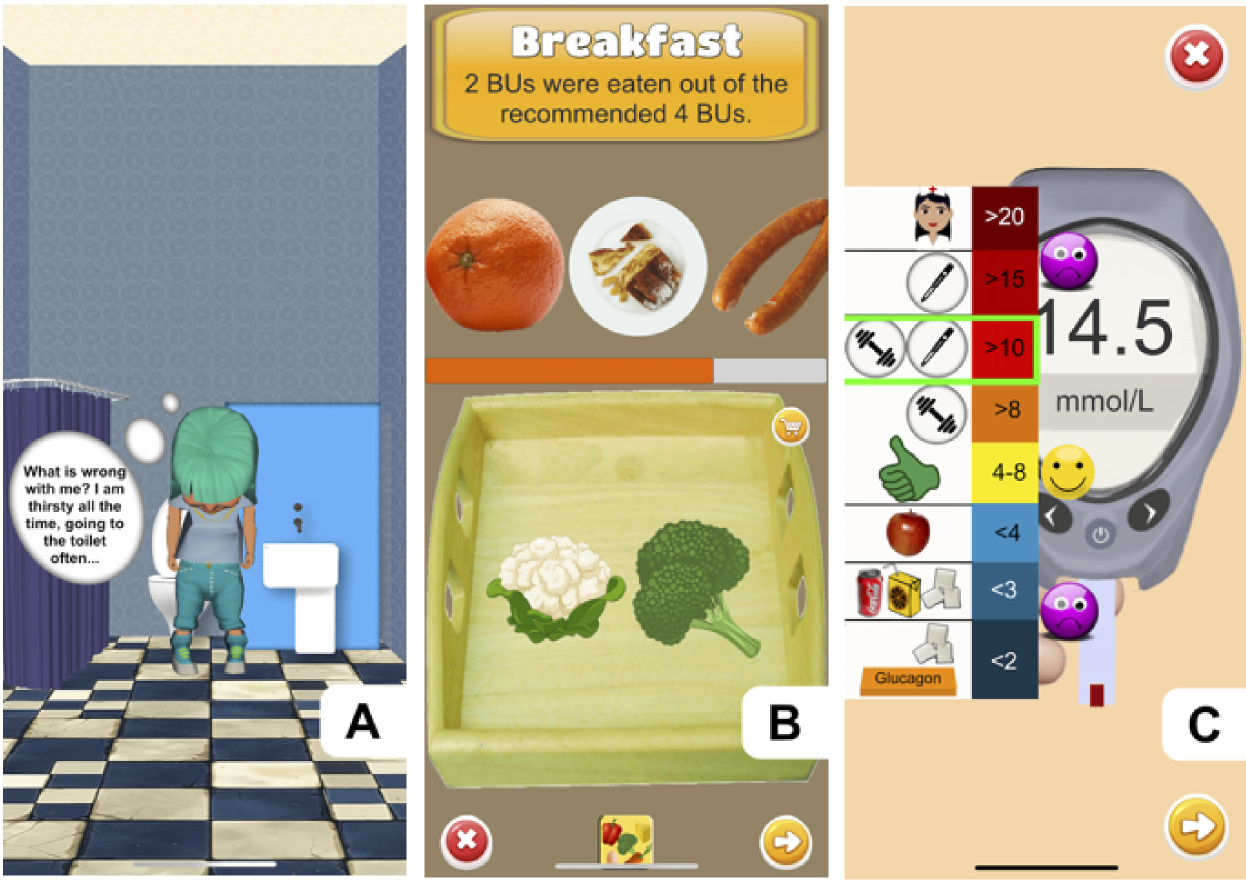
When designing the game, the choice was driven by the experience of children from quantitative research (refer to Table S3 in Multimedia Appendix 2): the most played game was Pou, which involves caring for a simulated creature, which is a proven gameplay principle of other successful games such as Moy, My Talking Tom, My Talking Angela, The Sims, and the older Tamagotchi. These games are based on the player taking care of a pet. Games of this type have had great success in the past and in recent times [34,41].

The primary design concept of the game divides the avatar's day into 6 parts, representing 6 meals, similar to the routine of a person with diabetes. The player's tasks include measuring the avatar's blood glucose level, administering insulin, and feeding the avatar. For completing these tasks, the player is rewarded with virtual coins, which can be used to enhance the avatar as well as buy new furniture, food, and other items. Neglecting the avatar's care can result in the avatar experiencing hypoglycemia or hyperglycemia, which the player can identify based on the virtual glucometer reading and the avatar's symptoms.

Onboarding and Tutorial

The game includes an introduction in which the avatar experiences the initial symptoms of diabetes and is transferred to the hospital in an ambulance, where it is diagnosed by a physician (Figure 2A).

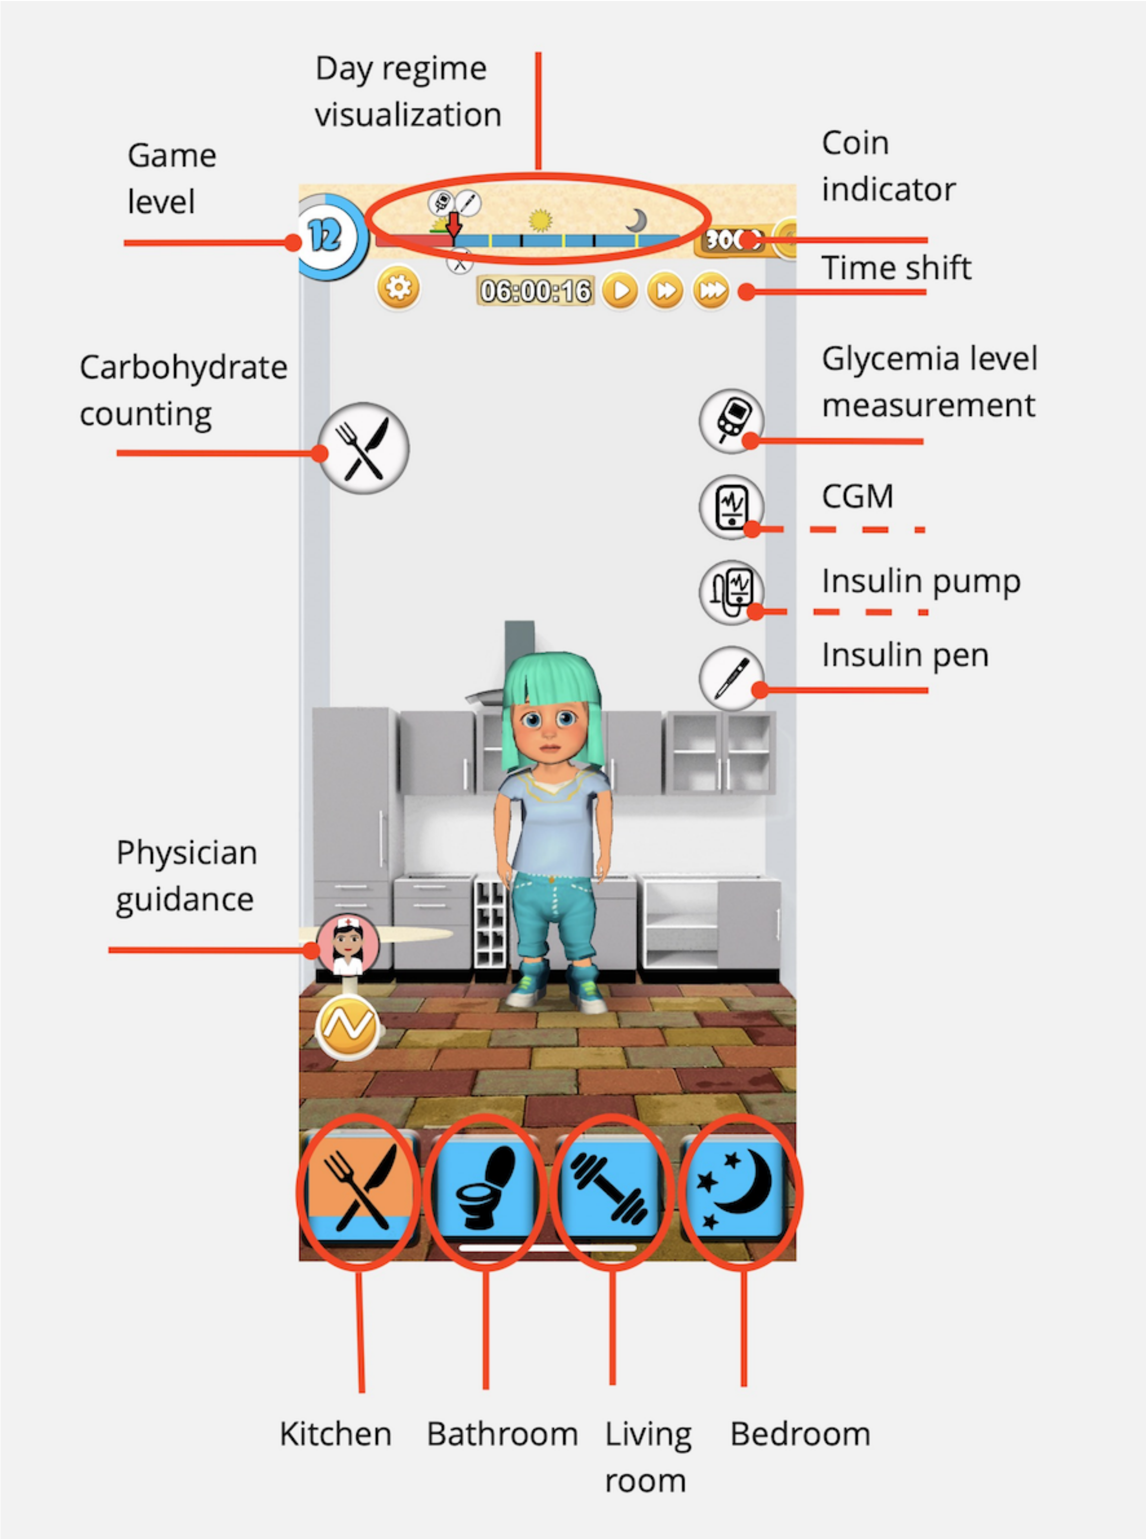
Figure 2. (A) Onboarding, including the first symptoms and diagnosis. (B) Carbohydrate counting. (C) Measuring blood glucose level using a glucometer. BU: bread unit.



Control Elements

Herein, the control elements of the game are described using the example of a kitchen scene (Figure 3). The different rooms are represented by an icon in the bottom panel. Each icon serves not only as a switch to access that room but also to indicate whether one of the avatar's basic needs, such as sleep or food, is met. In the upper left corner, the player is reminded of the level the avatar is currently in. The key is to follow the daily routine, which can be seen on the timeline. The timeline is the same every day. During the repetition of basic actions, the player learns about the problem.

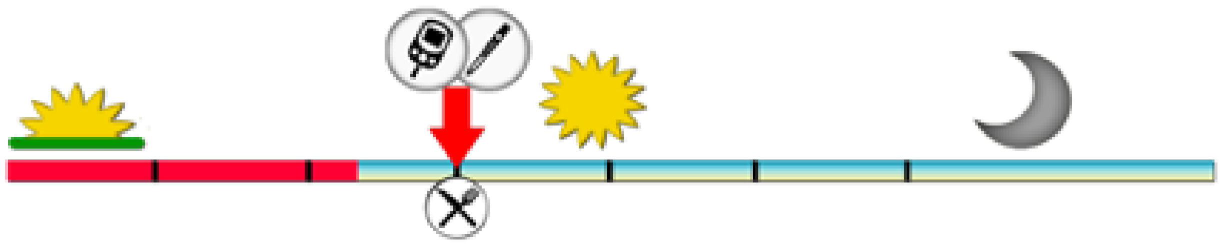
Figure 3. Description of the control elements. Continuous glucose monitoring (CGM) and insulin pen features were added in the final iteration (iteration 3) and appear in level 5.



If needed, time can be accelerated using the designated button. The amount of coins currently available in the avatar's cashbox is displayed on the right side.

To remind players of basic tasks such as measuring blood glucose levels, injecting insulin, and eating, a timeline was designed that always shows 1 task ahead, and all tasks are marked on the timeline so that the player knows approximately when the next task will occur (Figure 4).

Figure 4. Illustration of the timeline for the day regime of a person with diabetes.



Carbohydrate Counting

The player must choose the proper combination from the offered food items to achieve the specified number of BUs as closely as possible. The offered food items will be selected randomly from the purchased food so that the player cannot cheat (eg, by learning the BU component of only 1 food item and repeatedly giving it to the avatar). The player can see food items as a picture of food on a plate to estimate the amount of food based on the plate size (Figure 2B).

Glycemia-Level Measurement

There is no blood glucose–level indicator in the game. The player determines the exact blood glucose level by measuring it, for which they receive a reward. The virtual measurement mimics the real measurement (Figure 2C). The needle of the lancet becomes dull over time and needs to be replaced. A limited number of test strips are inserted into the pen and run out over time. The player must buy new needles and test strips in the virtual store with the collected coins. Estimating the blood glucose level based on the avatar's current mood is possible; for example, in the case of hypoglycemia or hyperglycemia, the avatar appears sick and in a bad mood (Figure 5C).

Figure 5. (A) Performing exercise. (B) Administration of insulin with an insulin pen. (C) Visualization of the symptoms of acute hyperglycemia.

Administration of Insulin

Insulin administration too mimics real-world settings. The player learns certain habits, such as pointing the needle skyward, giving the pen a little flick or tap to loosen any bubbles to the top, and performing an *airshot* (expelling air, thus priming the needle for injecting and avoiding possible air bubbles in the cartridge). The user is first required to assemble an insulin pen by removing the cap from the pen, taking a new needle, removing it from the sterile packaging, inserting it in the pen, and removing the needle cap and needle shield (Figure 5B). The game only allows the user to inject insulin once the needle has been primed for injecting. The game advises the user on the appropriate dose of insulin, as well as the type of insulin to administer to the avatar. The user administers short-acting insulin before main meals and long-acting insulin at night. Changing the needle and changing the insulin cartridge (the amount of insulin in it gradually decreases) are also incorporated.

Performing Exercise

The avatar requires regular exercise; otherwise, the avatar will be in a bad mood. The player determines the duration of the exercise (Figure 5A). If the exercise is too long, the avatar goes into hypoglycemia. The muscles tend to be more insulin sensitive for 1 to 2 days after exercise, leading to an increased risk of hypoglycemia, but this is not implemented in the game. To motivate the player to be active, the game offers them bonus coins for performing physical activity. If the player owns a Fitbit fitness bracelet, it is possible to connect it to the game and receive a virtual coin for every 2 steps taken in real life.

Alpha Usability Testing

The main aim of alpha usability testing was to determine users' experience and assess their understanding of the main game concept. In total, 12 children participated in alpha testing (refer to Table S4 in Multimedia Appendix 2): 7 (58%) with diabetes (n=5, 71% boys and n=2, 29% girls; aged between 6 and 13 years) and 5 (42%) without diabetes (n=2, 40% boys and n=3, 60% girls; aged between 6 and 13 years). The involvement of children without diabetes is important to address the reduction of stigma and to provide education to friends and schoolmates. The recruitment was performed through the Association of Parents and Friends of Diabetic Children. The testing was organized at participants' premises and consisted of completing the pretesting screener (refer to the Screener subsection under Alpha Release in Multimedia Appendix 1) and testing (onboarding and going through all 4 basic screens). One observer was always present to take notes.

Regarding user experience and game mechanics, all participants were satisfied; they liked the design and were able to find their way around in all scenes, although only after several attempts. Most users asked for help, both written and audio. Some users were looking for basic educational information about diabetes. The majority of users mentioned the issue of long-term motivation to use the game regularly. The main feedback is summarized in the Feedback Summary subsection under Alpha Release in Multimedia Appendix 1. Most shortcomings were addressed in future development in iterations 2 or 3.

Iteration 2: Educational and Gamification Features

Overview

On the basis of the outcomes of the usability alpha testing and continual feedback from the clinical team (nurses and physicians), in the next iteration phase, the focus of the main design effort was on increasing adherence, game experience, and educational impact by incorporating (1) game level design (Figure S2B in Multimedia Appendix 1); (2) minigames concept and storyline (Figures S3A, S8A, and S8B in Multimedia Appendix 1); (3) virtual guidance; and (4) an educational library, including the simulation of glycemia [42] (refer to the Theoretical Background and Game Design section in Multimedia Appendix 1 for a description of the new add-ons). Incorporating the audio guidance helps preschool children who cannot usually read yet to better orient themselves within the game. The main aim of the feasibility follow-up testing was the determination of educational and adherence effects.

Beta Usability Testing

The recruitment was organized via Facebook groups and targeted children aged 5 to 15 years willing to play the game for at least 1 week. Children without diabetes were not included because this feasibility test aimed to determine the educational and adherence effects in children with T1DM. In addition, adherence was tested by inspecting game statistics implemented by applying the Google Analytics framework.

Individual Interviews

The interviews were conducted in person with the participant and their parents. The first questionnaire was the screener (refer to the Screener subsection under Beta Release in Multimedia Appendix 1), which helped to place the children in the correct category corresponding to the desired target group of the participants. This was followed by a general questionnaire (refer to the General Questionnaire subsection under Beta Release in Multimedia Appendix 1) to estimate the participant's interest in games. Furthermore, the participant was asked questions regarding their management of their diabetes (refer to the Diabetes Management subsection under Beta Release in Multimedia Appendix 1). The user was also presented with a questionnaire on diabetes education (refer to the Pretesting Knowledge of Diabetes subsection under Beta Release in Multimedia Appendix 1). Subsequently, the game was installed on their mobile device. This was followed by observation of the participant and their behavior as they undertook the first steps in the game. The participant was required to go through the whole game tutorial and later try to find their way around the game for a few minutes. The gameplay was then interrupted, and the participant was asked about first impressions (refer to the First Impression of the Game subsection under Beta Release in Multimedia Appendix 1). The participant's parents were then interviewed (refer to the Questionnaire With Parents subsection under Beta Release in Multimedia Appendix 1). The main findings of the interviews are summarized in Table S5 in Multimedia Appendix 2. Seven participants took part in the study, of whom 1 (14%) did not complete the usability testing and was excluded. Of the remaining 6 participants, 1 (17%) was a boy and 5 (83%) were girls, and they were aged 5 to 15 years. The average duration of diabetes was 4.8 (SD 2.9) years; 4 (67%) of the 6 participants were using an insulin pump.

Beta Usability Testing

The participant was asked to play the game for at least 1 week, after which they were contacted by telephone, and the second part of the test questionnaire was discussed. First, the participant was asked about their impressions of the app after the 1-week testing (refer to the Beta usability testing subsection under Beta

Release in Multimedia Appendix 1), followed by a knowledge questionnaire on diabetes (refer to the Posttesting Knowledge of Diabetes subsection under Beta Release in Multimedia Appendix 1). The educational effect of the game is outlined in the next subsection. Regarding the usability testing results, the main findings are summarized in Table S6 in Multimedia Appendix 2.

In summary, the participant group consisted of children in different age ranges. Of the 7 participants, 2 (29%) were aged <7 years and could not read; 1 participant (14%) could not complete the usability testing because he required hospitalization. Of the 4 participants aged 8 to 12 years, 3 (75%) expressed high levels of enjoyment and found the game entertaining. Evidently, all children in this category understood the game well, confirming the study hypothesis that this age group should be the primary focus. Of the 6 participants who completed the testing, the remaining 2 (33%), aged 13 to 15 years, also understood the game well, although they commented that the entertainment aspect could have been more engaging. They highly recommended the game to younger audiences and stated that they wished such an educational tool had been available when they had been first diagnosed with diabetes. In general, the girls particularly enjoyed shopping, while the boy was more interested in minigames.

Educational Effect

Table 2 summarizes the educational impact based on the answers to the questionnaires, showing the level of education before and after the testing. The specific percentage response rates are given in Tables S7 and S8 in Multimedia Appendix 2. This score is expressed as a percentage depending on the quality of the correctly answered questions and the degree of confidence in answering them (assessed subjectively). If the answer is accurate and complete (correct), then 100% is given for this question. If the answer is partially correct or incorrect, a percentage measure of accuracy is estimated, where 0% is given for an outright nonsensical answer or if the participant does not know the answer.

Table 2. Effect of education.

	Educational score before testing (%)[a]	Educational score after testing (%)[b]	Difference (%)[c]
Participant 1	39	44	5
Participant 2	96	98	2
Participant 3	27	55	28
Participant 5	80	93	13
Participant 6	84	95	11
Participant 7	89	94	5

[a]Average 69.2.

[b]Average 79.8.

[c]Average 10.7.

Table 2 depicts the results of the educational effect after 1 week of usability testing. On average, the increase in education knowledge was approximately 10%; in the particular case of participant 3, the gain was considerably high: 28%.

Statistics Summary

Regarding game analytics, a significant improvement in skills was observed throughout the gameplay, specifically in the time taken to perform certain procedures. The time taken for glycemia-level measurement decreased by 42%, and the time taken for insulin administration decreased by 45% from the first interaction (day 1) to the last interaction (day 7).

Analyzing the purchase behavior of players, the most frequently bought food items were the large basket (46%), followed by the medium-sized basket (26%), and the small basket (28%). As for medical supplies, the majority of purchases consisted of glucometer strips (59%), followed by lancet packs (18%), injectable lancets (12%), and insulin (11%).

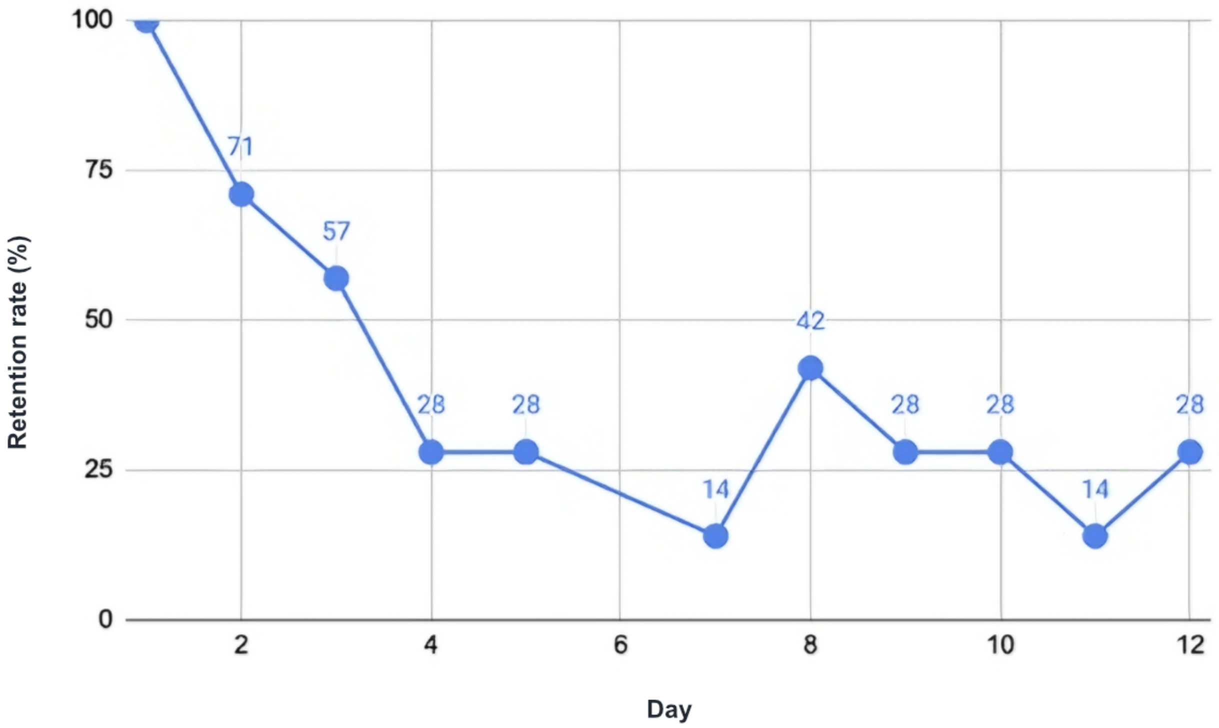
Examining the distribution of glycemia statistics, glucose measurements were most commonly applied on the middle finger (50%), followed by the index finger (22%), ring finger (19%), little finger (6%), and thumb (3%). Short-term insulin injections were most frequently applied to the abdomen (29%), left biceps (12%), and left thigh (7%). Long-lasting insulin injections were predominantly applied to the left and right thighs (11% and 12%, respectively) and to the chest (6%). The less frequent injection site was the right thigh 0.78%, of the 129 injections recorded.

During the gameplay, the avatar was hospitalized 31 times, with 15 (48%) of the cases involving hypoglycemia and 16 (52%) involving hyperglycemia. The average blood glucose level during these hospitalizations was 15.7 mmol/L. In addition, the avatar engaged in exercise 72 times, with 36 (50%) of the sessions lasting for 30 minutes, 19 (26%) for 90 minutes, and 17 (24%) for 60 minutes. However, the exercise was completed in only 32 (45%) of the cases, with early terminations occurring in the remaining 40 instances (55%).

The final phase of the usability testing focused on measuring adherence. At the beginning of the game, the day and time were recorded to mark the initial interaction. Subsequently, for each following day, whether the player returned to the game was noted. The retention rate, depicting the percentage of players who continued playing the game over time, is illustrated in Figure 6.

In the first week, the participants tested the game without any intervention. The telephone interview was performed on day 7. As shown in Figure 6, the adherence rate was >14%, and on the following day, day 8, the rate increased to 42% after the interview. The time spent playing the game on day 1 was approximately 39 minutes per user; on day 7, it was approximately 25 minutes. Some participants even played the game for 1.5 hours on 1 day. The daily average time for all participants was approximately 17 minutes.

Figure 6. Retention rate of participants.



Participant Feedback

Given the high number of participants (70%) using insulin pumps, it was unsurprising that there were requests to add insulin pump functionality and CGM in the game. Some users also expressed a desire for more advanced tools, such as the ability to administer glucagon and measure ketoacidosis. In response to this feedback, these features were included in iteration 3 of the game.

Of the 6 participants, 2 (33%) indicated that the game became routine after a certain period and that they desired some variation. Of these 2 participants, 1 (50%) suggested that a solution could be to introduce complications related to diabetes, such as cardiovascular issues, neuropathy, or retinopathy, which the player would need to manage.

In the real world, various types of insulin are available, each designed with different properties regarding onset, peak, and duration. Participants expressed the desire to be able to purchase and use the specific insulin types that they are familiar with and to understand their characteristics within the game.

Iteration 3: Advanced Technological Components

On the basis of the feedback received from the beta usability testing, in this iteration, more advanced tools for diabetes management were implemented. Subsequently, the final usability study briefly evaluated the new modules.

CGM and Insulin Pump Implementation

This module illustrates the use of the application of the CGM sensor (Figure S4 in Multimedia Appendix 1) and tethered insulin pump (Figures S5 and S6 in Multimedia Appendix 1). When the player's blood glucose levels reach a certain threshold (>5mmol/L), the advanced technology of using a CGM sensor and an insulin pump becomes available, unlocking new features and options in the game (see insulin pen and insulin pump icons in Figure 4).

Glucagon Administration

Glucagon administration is an essential treatment for severe hypoglycemia, particularly when a person with diabetes cannot consume food or fluids because they are in a hypoglycemic coma [12]. Another individual must administer the glucagon injection in such cases. The selected design closely resembles the real-life GlucaGen HypoKit (Novo Nordisk A/S) and visually represents the glucagon injection process (Figure S7B in Multimedia Appendix 1). The glucagon administration icon will be displayed when the avatar experiences hypoglycemia, indicating the appropriate action to take.

Measuring Ketoacidosis

Specifically, patients treated with continuous subcutaneous insulin infusion have a greater risk of developing diabetic ketoacidosis because there is no subcutaneous depot of insulin, and therefore ketoacidosis can occur much faster [1]. As the measurement of ketone bodies from urine using diagnostic strips is the most common and most accessible method in the home environment, the focus is on designing the scene using the home kit (Figure S7C in Multimedia Appendix 1). To simulate the level of ketoacidosis, the simplify model from the work by Fabietti et al [43] was applied (refer to the Ketoacidosis Module Implementation section in Multimedia Appendix 1).

Gold Usability Testing

The primary objective of the usability testing was to evaluate the technical feasibility of the advanced modules. Participants were recruited from a summer camp for children with diabetes. In the first phase, a general questionnaire was administered to assess the participants' knowledge about diabetes compensation. A total of 30 participants (n=12, 40% boys and n=18, 60% girls) aged between 7 and 15 years completed the questionnaire (refer to Table S9 in Multimedia Appendix 2). In the second phase, the 24 participants completed the tutorial (refer to the Onboarding and Tutorial subsection) together. Finally, the participants were divided into 3 groups to test the insulin pump and CGM sensor module (9/24, 37%), the ketoacidosis measurement module (7/24, 30%), and the glucagon administration module (8/24, 33%). Before testing, a pretesting questionnaire (refer to the Pretesting Questionnaire subsection under Gold Release in Multimedia Appendix 1) was administered. The usability testing session was conducted by a researcher, who explained the main goals to be achieved in each group in several steps.

A cohort of 9 participants (n=2, 22% boys and n=7, 78% girls) were enrolled to test the insulin pump and CGM sensor module. The study required the participants to complete several tasks, including applying the glucose sensor and insulin pump infusion set, calibrating the sensor, and spending a portion of the day using the sensor and the pump. The summary of the testing is provided in Table S10 in Multimedia Appendix 2. Overall, the insulin pump and CGM sensor module were rated positively for their realism; however, participants reported that certain complications were not accounted for in the game, such as disconnecting the infusion set from the reservoir, the possibility of the pump tubing becoming kinked and clogged, and adding insulin to the reservoir. During the pump assembly (refer to step 2 in Table S11 in Multimedia Appendix 2), participants had difficulty connecting the reservoir to the infusion set using tubing and squeezing the air out of the tubing by long pressing the button on the tank. In addition, confusion arose during the insulin infusion scene because participants needed clarification on how many units of insulin they should inject. Improvements in this scene could help better convey the necessary information to the player.

Eight participants were involved (n=4, 50% boys and n=4, 50% girls) in the testing of the glucagon administration module (refer to Table S12 in Multimedia Appendix 2). All participants were able to administer glucagon; however, sometimes the game took longer than expected due to minor bugs or nonintuitiveness, such as using a click gesture instead of a drag-and-drop gesture, which caused problems in cases of drawing the solution back into the syringe and then removing the syringe from the vial or removing the protective cover of the syringe. All participants praised the realistic handling of the game.

The ketoacidosis measurement module was successfully tested by all 7 participants (n=2, 28% boys and n=5, 72% girls), who found the scene good and did not suggest any improvements (refer to Table S13 in Multimedia Appendix 2). Only 1 (14%) of the 7 testers did not observe an increase in ketone bodies when insulin was not administered to the avatar. When asked about alternative methods of measuring ketones, most participants expressed openness to new options beyond diagnostic strips, especially for children accustomed to different measurement methods.

Discussion

Principal Findings

The main objective of this paper was to provide education mainly to children newly diagnosed with T1DM by using mobile technologies and gamification theory for educational purposes. The inclusion of gamification in diabetes management offers additional benefits compared to current methods, particularly in terms of improving patient motivation [4,5]. Given the widespread use of mobile technologies among young children, a mobile app is an ideal platform for introducing this serious topic to them entertainingly and engagingly. This approach involves combining various techniques, such as gamification theory [24] as well as topics from behavioral theory, such as tailoring [11], observational learning [29], decision-making practice [13], social and family support [30,31], and reward systems [32], to support patient motivation and compliance.

The game provides comprehensive education for children on various aspects of diabetes, including technical skills such as measuring blood glucose levels and administering insulin, as well as explanations of the nature of the disease. As a result, the game should be considered an additional resource for children newly diagnosed with T1DM to learn about the disease, along with books and brochures. The game's virtual avatar can also serve as a supportive friend for children unable to attend diabetes camps.

In addition, the game has the potential to raise awareness of diabetes among children without diabetes as well as parents [1]. By increasing knowledge of the disease and its symptoms, the game can aid in earlier diagnosis and treatment of diabetes. Initial feedback from children with T1DM and their parents on the game has been positive, with many expressing enjoyment and a willingness to participate in further testing.

Concerning the educational effect of the game, after a week of testing, there was a noticeable improvement in the educational outcomes (refer to Table 2). When compared to a previous study [16], it can be inferred that the improvement rate in educational outcomes is similar (33%). However, it is important to consider that the game in that study was tested for a year, while in this study, testing only lasted a week. In comparison, another study [18] reported an improvement rate in educational outcomes of 7% only. MyDiabetic aims to enhance traditional patient education formats (such as patient information booklets [44]) rather than replace them.

Recent literature reviews on gameful eHealth and mobile health tools have indicated that the most commonly used game elements are externally oriented, such as points and rewards [45,46]. The concept of avoiding excessive use of externally oriented motivational features has also been explored in theoretical works on designing engaging and gameful experiences [47]. Nevertheless, in a review of similar apps targeting gaming in T1DM (refer to Table S14 in Multimedia Appendix 2), authors found that the archetypal game elements of points, badges, and competitions were the primary approaches used [48]. MyDiabetic involves using rewards to purchase food, goods, and healthy supplements, which appeal to most children. The shopping aspect serves as an educational tool that prepares young children to increase self-efficacy in managing their T1DM, consequently reducing their dependence on their parents [5,17].

One of the most effective aspects of the co-design process in achieving design goals was the participation of clinicians, patients, family caregivers, developers, and game designers. Participants brought their unique expertise to the table and contributed to the design process; for example, health care researchers provided knowledge and feedback on diabetes compensation, while the developers and designers worked on making the tool user-friendly, and the external game designer suggested more interactive and immersive solutions. Research indicates that collaborative, team-based approaches are recommended for developing mobile health interventions [49]. The strategic coordination of stakeholder involvement at each stage of development was a key benefit of this design approach.

Although there is still no consensus on the optimal combination of game mechanics for serious games [34], it is acknowledged that MyDiabetic currently leans too heavily toward education, leading to lower retention rates than anticipated. Drawing from the insights gained during the second and third rounds of the iterative usability studies, it is proposed to redesign the game by incorporating multiple storylines, such as school experiences, dating, and career development, to enhance the entertainment factor and introduce new topics as the avatar ages. The existing educational components will be seamlessly integrated into the game mechanics to improve overall gameplay and increase engagement. This new direction should also provide an easier transfer of knowledge and skills from this serious game to real-world situations [34].

Limitations

Initially, all participants involved in the study voluntarily opted to participate or were contacted by the project team or collaborating institutions. Consequently, the participating groups may have had higher motivation, resourcefulness, and better chronic illness management, thus creating a potential bias that may only represent a portion of the user group. Nonetheless, this is a common limitation in this type of research.

While the sample sizes were indeed modest in the alpha, beta, and gold testing phases (12, 6, and 24 participants, respectively), the significance of the results lies in the qualitative insights and detailed observations that were gathered through iterative usability testing. This process enabled deep delving into the experiences and perceptions of each participant, yielding rich and meaningful data on the game's usability and educational impact. Furthermore, the results that were obtained from the limited numbers of participants were consistent and provided actionable insights for further refinement and development of this serious game.

The design outcomes were influenced by the stakeholders involved in the project, who had the potential to both positively impact and limit the final design. One example is the nutrition nurse who facilitated the design activities but had limited design experience and had to learn co-design processes as the project progressed.

The MyDiabetic app was developed and evaluated solely by Czech users, although an English version is now accessible. There may still be cultural discrepancies that have not been fully addressed. The project team constantly receives feedback and makes necessary adjustments to improve the app's usability and relevance.

It is important to note that this paper focuses solely on the technical development of the game and user acceptance testing. The clinical validation of the game, using metabolic control markers such as mean glycated hemoglobin levels, is beyond the scope of this paper. While it is important to evaluate the effectiveness of the game in improving diabetes management, this will be the subject of future research.

Comparison With Prior Work

After examining the survey presented in Table S14 in Multimedia Appendix 2 [13,16,18,19,21,24-31,33,42,43,50-65], it was observed that all games, except Packy & Marlon [16], lacked clinical validation. Furthermore, assessing adherence was not a focus in any of the games. In addition, of the 18 games, 3 (17%) were previously available on Nintendo or mobile game stores, but currently only 2 (11%; MyDiabetic and Jerry the Bear) are available for download on mobile game stores. Most games were developed as prototypes or concept studies as part of academic projects, with only a few aimed at preschool children [50-52]. Only 1 (6%) of the 18 games addresses both basic (carbohydrate counting, blood glucose–level measurement, and insulin administration) and advanced (CGM and insulin pump) educational self-management skills [50]. Nevertheless, no game tackles the complexity of diabetes management from such a wide perspective as MyDiabetic, in which unique features such as glucagon administration and ketoacidosis modules are included.

One of the challenges that serious game designers face is the *uncanny principle*, also known as the *uncanny valley*. This phenomenon occurs when a representation of a human or an animal looks and behaves almost but not exactly like the real thing [66]. The result is a feeling of eeriness, discomfort, or even revulsion in the observer. The *uncanny principle* can affect the learner's immersion, engagement, and emotional connection with the serious game. The *uncanny valley* can be useful for creating more effective and engaging serious games. By carefully navigating the *valley* and finding the right balance between realism and abstraction, game designers can create experiences that are both educational and emotionally compelling [67]. MyDiabetic aimed to strike this balance by using cartoonish avatar designs and environments, while carefully incorporating technology features that closely resemble real-world settings, setting it apart from most other games [16,50].

Future Directions

To enhance the game's realism, it would be beneficial to incorporate real-time elements. This would involve the avatar aging as time passes In addition to managing diabetes symptoms, the avatar would also engage in typical daily activities such as attending school/work, participating in outdoor sports, visiting friends, and partaking in entertainment (Figures S8A and S8B in Multimedia Appendix 1). In addition, chronic retinopathy or diabetes foot problems would also be demonstrated (Figure S8C in Multimedia Appendix 1). By including these elements, the game could provide a more comprehensive experience for users and better prepare them for managing their diabetes in real-life situations.

Including social support in the app could be an additional valuable feature [68]. Games that allow users to connect with others in a community-type setting or through social networks could be particularly beneficial because research suggests that increased social support is linked to improved self-efficacy practices and better clinical outcomes in children with diabetes. A review of studies also found that social media were commonly used to facilitate self-care in patients and caregivers, with 77.1% of the identified studies reporting such use [69].

Conclusions

This paper has shown how participants involved in co-design activities played a creative and productive role in shaping the content and design of the MyDiabetic app.

The main objective of creating a serious educational game was to captivate children with T1DM and also make it accessible to those who are interested in learning about the disease. On the basis of the testing described earlier, the educational goal was achieved because significant enhancements in children's understanding were evident after a mere week of gameplay. The game was well-received by the participants, who expressed a willingness to recommend it to their friends or siblings who are not affected by diabetes but are curious about the disease and would like to understand it better.

To summarize, this research suggests that the target audience for this game is children aged between 5 and 12 years, with those in the 8- to 12-year range being able to fully engage with and benefit from all the features the game offers.

Acknowledgments

The author expresses his gratitude to his students who designed and implemented MyDiabetic in their final projects (2016-2022): Veronika Cernohorska for the main concept, Jana Kejvalova for carrying out the user testing, Lukas Rubes for integrating the onboarding, Dusan Jencik for designing the levels, Natalie Zubkova for integrating the educational library, Victoria Eykhmann for the glucagon administration module implementation, Eva Uliarikova for implementing the measurement of ketoacidosis, Petra Salficka for storyline development, and Benjamin Hejl for continuous glucose measurement and insulin pump deployment as well as project management. The author's gratitude also goes to the clinicians who provided invaluable insight and support for the game during the design phase—Ludmila Brazdova (Brothers of Mercy Hospital) and Jaroslav Skvor (Masaryk Hospital) contributed significantly to the first iteration by offering insights into common T1DM principles. In addition, Jaroslav Skvor provided input regarding the role of physical exercise. In the second iteration, Katerina Stechova (University Hospital in Motol) shared valuable comments concerning the blood glucose simulator and adherence principles in children. For the third iteration, Milos Mraz (Institute for Clinical and Experimental Medicine) contributed his expertise on the CGM module and insulin pump, while Zdenek Sumnik (University Hospital in Motol) offered critical feedback on gamification principles. The author also thanks to patients' organizations for facilitating access to children with type 1 diabetes mellitus during the participatory design and feasibility studies—Vaclav Letocha (Association of Parents and Friends of Diabetic Children), Sarka Nosalkova (Center for Children with Diabetes), and Zdenka Stankova (Diacel)—and finally to game designers Michal Berlinger (Amanita Design) and Lucie Workova. The study was supported by the Research Centre for Informatics (CZ.02.1.01/0.0/16_019/0000765) and by the biomedical data acquisition, processing, and visualization (SGS22/165/OHK3/3T/13) grant. The author used generative artificial intelligence (ChatGPT, OpenAI) for proofreading this manuscript.

Abstract

Background: Due to a high number of patients affected by long COVID or post-COVID condition, an essential step to address the long-term effects of COVID-19 lies in the development and implementation of flexible and accessible rehabilitation programs. Virtual reality (VR) technologies offer the potential to support traditional therapies with individualized at-home programs.

Objective: This study aims to provide an overview of existing scientific evidence on the development and implementation of VR-assisted respiratory rehabilitation programs for patients with long COVID and post-COVID condition and to synthesize the results.

Methods: We conducted a scoping review of studies from 6 databases. PubMed, CINAHL, Cochrane, ScienceDirect, Web of Science Social Sciences Citation Index, and PEDro were searched using an exploratory search strategy. The search, which was last updated in February 2024, included peer-reviewed studies on immersive VR applications providing respiratory rehabilitation programs for patients with chronic obstructive pulmonary disease and long COVID or post-COVID condition. Exclusion criteria were studies in clinical or inpatient settings, telemedicine, nonimmersive VR applications, and gray literature. Nine publications were included in this review. Findings were extracted and summarized from the studies according to the JBI (Joanna Briggs Institute) method and thematically categorized. Topics covered were study characteristics, physiotherapeutic concept, clinical parameters, as well as usability and acceptability.

Results: The 9 publications included in the qualitative analysis were published in 2019-2023. Eight empirical studies were included: 4 followed a mixed methods design, 3 were qualitative studies, and 1 followed a quantitative method. One scoping review was included in the data analyses. Four of the included studies were on patients with chronic obstructive pulmonary disease. The 9 studies demonstrated that VR-supported respiratory rehabilitation programs result in positive initial outcomes in terms of physical as well as psychological parameters. Particularly noteworthy was the increased motivation and compliance of patients. However, adverse effects and lack of usability are the barriers to the implementation of this innovative approach.

Conclusions: Overall, VR is a promising technology for the implementation of individualized and flexible respiratory rehabilitation programs for patients with long COVID and post-COVID condition. Nevertheless, corresponding approaches are still under development and need to be more closely adapted to the needs of users. Further, the evidence was limited to pilot studies or a small number of patients, and no randomized controlled trials or long-term studies were part of the study selection. The included studies were performed by 4 groups of researchers: 3 from Europe and 1 from the United States.

Introduction

Background

In the wake of the COVID-19 pandemic, the rehabilitation of patients in the postacute phase of this disease is an important measure to address the long-term effects since a significant number of patients experience the condition commonly known as long or post-COVID [1]. This condition is characterized by symptoms that persist or develop after the acute phase of infection—starting from the fourth week after infection—and that cannot be explained by an alternative diagnosis [2,3]. The number of affected patients varied in the studies depending on the methodology, symptoms, as well as the population included in the analysis. Although studies provide heterogeneous results and case numbers, they show that a significant number of patients are affected by persistent symptoms after a COVID-19 infection. Patients who report an impact on everyday functioning up to 3 months after testing negative account for 10%-50% of the study participants [4]. According to a study by Peter et al [5] conducted in 2020 and 2021, including 11,710 patients from Germany, 28.5% of the patients reported persistent symptoms for 6-12 months after infection with COVID-19. That study further estimated that at least 6.5% of the adult patients in the general population who had recovered from COVID-19 infection were affected by long-term symptoms such as fatigue, dyspnea, neurocognitive impairments, and chest pain [5]. As per the World Health Organization, in the European region approximately 20% of the patients developed symptoms mentioned above continuing for at least 3 months after recovery according to a meta-analysis [6]. In addition, psychological symptoms such as anxiety and stress can have a negative impact on the quality of life caused by the abovementioned long-term effects [4,7].

After the treatment of acute symptoms is completed, patients need postacute rehabilitation, where physical therapy plays an important role in the treatment of lung-specific symptoms. For the best treatment possible, outpatient programs as well as solutions for the implementation of therapy programs in the home environment have to be established [8,9]. Pulmonary therapy approaches for chronic diseases such as chronic obstructive pulmonary disease (COPD) designed to normalize respiratory function have been well-established and are guiding the development of therapies for patients with long COVID or post-COVID condition. Therapy approaches include mobilization exercises, endurance, as well as strength training [10-14]. Since many patients experience psychological symptoms from the effects of impaired respiratory function, it is necessary to guide, counsel, and train patients in the use of appropriate strategies and coping skills when acute respiratory distress occurs [11].

Although the number of people affected by long and post-COVID symptoms remains high even as the pandemic situation continues to ease, there is still insufficient knowledge about the disease and a shortage of specialists and therapy programs [4,15]. In addition, the physical limitations of patients further impact their access to traditional physical therapy services. One way to address the shortage of adequate programs is to develop digital therapy solutions and assistive devices that are applicable in a home setting and can be individually applied without the constant supervision of specialist staff.

Initial findings suggest that digital approaches enable a more accessible implementation of therapies in the home environment and, at the same time, can contribute to increased motivation and adherence to therapy on the part of patients [16]. Previously established digital applications, for example, for patients with COPD have led to an increase in the quality of life, particularly with regard to emotional control and reduction in fatigue and dyspnea [17]. Virtual reality (VR) technologies are a solution to implement individual and flexible physical therapies in virtual space through the virtual representation of therapeutic measures and therapy situations. Approaches to integrate immersive VR applications already exist in various areas of rehabilitation as well as in psychotherapy, for example, to alleviate respiratory symptoms [18,19] and reduce anxiety and stress [20]. However, the implementation of respiratory therapy approaches for the home environment and especially programs for the target group of patients with long COVID/post-COVID condition are still under development. Further, a comprehensive review of the initial evidence on the development and implementation of appropriate VR applications does not yet exist.

Objectives

The aim of our literature review was to (1) obtain an overview of the findings in international research regarding VR-based respiratory rehabilitation programs for patients with long COVID/post-COVID condition and (2) obtain criteria for the development and implementation of respective VR applications for the home environment. Our scoping review addresses the research question: what scientific evidence exists on the development and implementation of VR-assisted rehabilitation programs for patients with long COVID/post-COVID condition that are implementable in a home setting? The selection and analysis of the studies were based on the following subquestions:

1. Which guidelines exist for the design of VR respiratory rehabilitation programs?
2. What are the enabling aspects? What are the barriers to implementation?

3. What clinical outcomes have been reported?

Methods

Study Design

The methodological approach of the JBI (Joanna Briggs Institute) method according to von Elm et al [21] was adopted as the basis of this scoping review to give a broad overview on the existing findings and identify established criteria in international research for the implementation of VR-assisted rehabilitation programs for patients with long COVID/post-COVID condition. Since only a small number of studies was expected regarding the patient group and the focus was on respiratory rehabilitation programs, conditions with a comparable symptomatic spectrum—such as patients with COPD—were also included. Results will be reported using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines (Multimedia Appendix 1). In preparation for this, a review protocol was developed but not published or registered.

Search Strategy

A sensitive database search was conducted using the databases PubMed, CINAHL, Cochrane, ScienceDirect, Web of Science Social Sciences Citation Index, and PEDro. The search was last updated in February 2024 in order to incorporate newly released studies. According to the search components—population, concept, and context—search terms were applied using Boolean operators, truncations, and proximity operators (see Textbox 1 and Multimedia Appendix 2).

Textbox 1. Search string using the example of the search in PubMed.

(((covid-19[MeSH Terms]) OR (respiratory*[Title/Abstract])) OR (pulmonary*[Title/Abstract])) AND (Rehabilitation[Title/Abstract]) AND (VR[Title/Abstract] OR virtual reality[Title/Abstract])

The identified studies were merged in the web-based tool “rayyan” [22] and screened by titles, abstracts, and full texts in regard to the research question, which was conducted independently by 3 researchers. Additionally, the reference lists of all the publications included in the full text screening were searched for further evidence. The inclusion and exclusion criteria for the studies were decided by team consensus (KD, IK, and HAE).

Study Selection

All types of studies published in the period between 2012 and 2023 that were available in English or German and provided with an abstract were included. The following inclusion and exclusion criteria were applied (see Textbox 2).

Textbox 2. Inclusion and exclusion criteria for the studies in this review.

Inclusion criteria

- Studies on immersive virtual reality applications providing respiratory rehabilitation programs, including breathing exercises, physical training, education, and programs introducing psychological counseling such as stress reduction for the home environment
- Studies including patients with long COVID, post-COVID condition, or chronic obstructive pulmonary disease
- Peer-reviewed empirical studies
- Mixed methods, qualitative, and quantitative studies

Exclusion criteria

- Clinical inpatient setting
- Telemedicine
- Virtual reality applications that are nonimmersive (applications for personal computers, augmented reality, etc)
- Gray literature (conference papers, opinion papers, study protocols)

Data Extraction and Synthesis

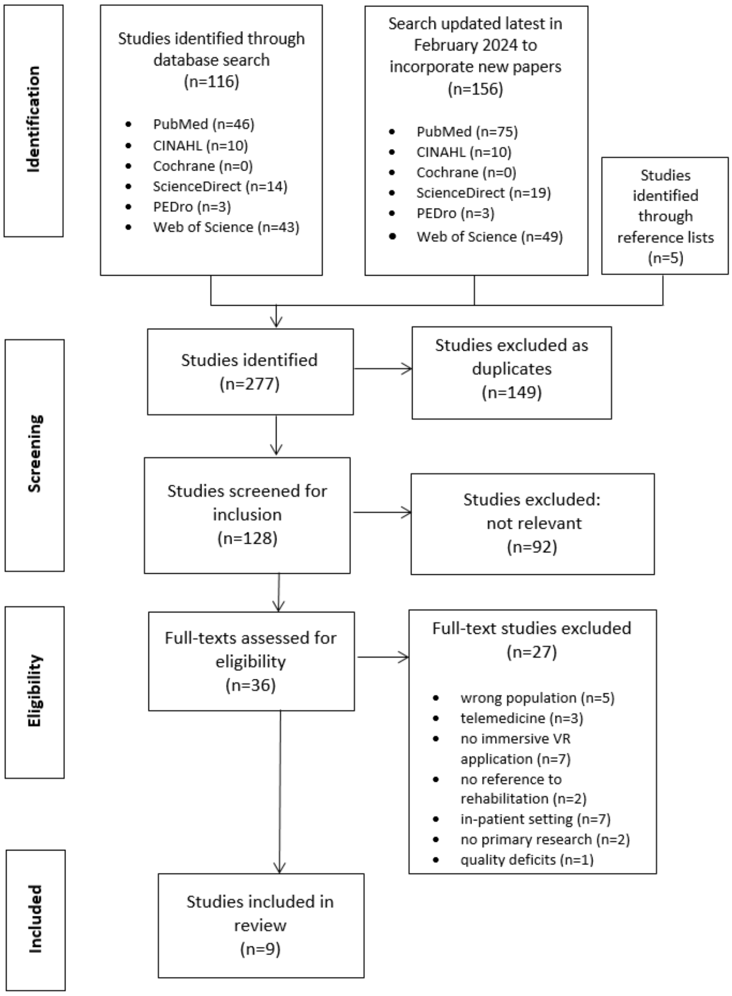
The characteristics of the identified studies were mapped in a preconsented data form (KD) and summarized narratively. Three researchers (KD, IK, and HAE) derived evidence on the development and implementation as well as the clinical outcomes of the studies concerning VR-based rehabilitation programs from the literature included in this analysis. The aspects identified were then categorized thematically, while study results covered the areas of study characteristics, physiotherapeutic concept, and outcomes in terms of clinical parameters as well as usability and acceptability aspects and were clustered and summarized according to the JBI method [21]. The categorization was then discussed within the research team.

Results

Overview

After duplicates were removed, 128 identified abstracts according to the above listed criteria were independently reviewed by 3 authors (KD, IK, and HAE). A full-text screening of the resulting 36 publications led to 9 studies, which were included in our review. Figure 1 shows the process of study selection in a PRISMA flowchart.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flowchart of the study selection process.



Characteristics of the Included Studies

The included studies were published between 2019 and 2023. The majority of the studies [23-28] were published since 2022. Six empirical studies were conducted in Europe and were limited to the Netherlands, United Kingdom, and Slovakia [19,25-29]. Further, 2 publications that refer to the same study conducted in the United States were included [23,24]. Four studies followed a mixed methods design [19,23,25,27], 3 studies were qualitative studies [24,28,29], and 1 study applied only quantitative methods [26] (Table 1). The data analyses included 1 coping review: in 2020, Colombo et al [30] reported VR applications and exergaming for pulmonary rehabilitation of patients with COPD. Both immersive and nonimmersive approaches were included. However, an assessment of the results with regard to the quality of the included studies was not performed. There was no systematic review on immersive VR rehabilitation programs for home settings and targeting patients with long COVID/post-COVID condition.

Table 1. Full list of the publications included in this scoping review.

Study, year	Objective	Study design	Population type	Sample size, n
Colombo et al [30], 2020	Literature review exploring findings on virtual reality and exergaming applications for pulmonary rehabilitation with focus	Scoping review	Patients with COPD[a]	N/A[b]
Gabriel et al [23], 2023	Qualitative evaluation of the feasibility of a pulmonary rehabilitation program, including educational content for patients with COPD	Mixed methods study	Patients with COPD	18
Gabriel et al [24], 2023	Qualitative evaluation of a pulmonary rehabilitation program for patients with COPD	Qualitative study	Patients with COPD	9
Groenveld et al [25], 2022	Evaluating self-administered virtual reality exercises at home for post–COVID-19 condition	Mixed methods study	Patients with post-COVID	48
Jung et al [19], 2020	Investigating whether virtual reality provides a credible alternative to traditional pulmonary rehabilitation programs and improves compliance among patients with COPD	Mixed methods study	Patients with COPD (Medical Research Council Dyspnea scale 4-5)	10
Lacko and Ruzický [26], 2022	Analyzing the use of virtual reality devices to rehabilitate patients in a controlled outpatient environment as well as in the home environment	Quantitative study	Patients with long-term COVID or post-COVID syndrome	16
Moorhouse et al [29], 2019	Evaluating a virtual reality pulmonary rehabilitation for patients with COPD	Qualitative study	Patients with COPD (Medical Research Council Dyspnea scale 4-5)	10
Ruzicky et al [27], 2022	Investigating the prevention, diagnosis, and treatment of patients after COVID-19 while using artificial intelligence and virtual reality in combination with traditional approaches to patient rehabilitation	Mixed methods study	Patients with post-COVID	10
Smits et al [28], 2022	Developing an evidence-based “Guidance ethics in context” for virtual reality development	Qualitative study	Patients with long COVID (n=20), physical therapists (n=15)	35

[a]COPD: chronic obstructive pulmonary disease.

[b]N/A: not applicable.

Synthesis of Results

The following section presents a synthesis of evidence from the included studies as the result of the qualitative analysis. The narrative description is based on the aspects of study characteristics, rehabilitation program, technical implementation, and evaluative and clinical outcomes.

Study Characteristics

The studies were first divided into 2 groups. The English research group led by Jung et al [19] and Moorhouse et al [29] and a US-American research group [23,24] tested VR applications designed for patients with COPD. They refer to the significance of continuous pulmonary rehabilitation, education of patients regarding the characteristics of their disease, and useful behavioral interventions. They also reported low compliance due to depression related to the condition, low awareness of the potential therapeutic approaches among patients, and lack of knowledge about the benefits of continuous therapy for chronic conditions. Immersive VR applications are intended to create an innovative motivating rehabilitation approach in this context [19,23,24,29]. The other publications refer to the development or evaluation of immersive digital rehabilitation programs for patients with long COVID or post-COVID condition [25-28]. Although the post-COVID condition, as already described in the introduction, refers to persistent symptoms from 4 weeks after a COVID-19 infection [26,27], other studies do not distinguish between long COVID and post-COVID condition at all [25]. Long COVID is usually described as a long-term consequence of infection with SARS-CoV-2 with various physical, psychological, and cognitive symptoms [25-28].

Ruzicky et al [27] collected data on symptoms and severity of the disease during COVID-19 infection and after recovery among a group of students and professors via a questionnaire. Based on the results, which included fatigue, fever, shortness of breath, and depression as common post-COVID symptoms, 2 groups of patients were included in the study. Ten patients had mild muscle pain and shortness of breath after mild exertion and another 6 patients were included who reported severe muscle pain along with shortness of breath [27]. None of the studies required a medical diagnosis or the submission of test results to verify if participants were actually infected with COVID-19; instead, studies relied solely on patient reports. Moreover, none of the studies provided further information regarding the characteristics of participants apart from gender and age or the cultural diversity of populations included. Studies have characterized VR as a way of facilitating access to therapeutic measures in the context of the pandemic [25,27]. In addition, 2 studies implemented individualized and multimodal therapy programs, which address both physical and psychological factors such as stress and anxiety [25,28]. Gabriel et al [23,24] further implemented educational content regarding pulmonary rehabilitation as part of the VR program [23,24].

Collection of Evaluative Data and Assessment

All the studies mentioned dealt with the evaluation of pulmonary VR rehabilitation applications by patients with regard to technology acceptance, usability, and criteria for implementation [19,23-29]. Only 1 publication also included the viewpoint of physical therapists in the assessment [28]. The majority of the studies used interview procedures as the qualitative data collection method [19,24,27-29]. Focus groups in which those affected by COPD were able to discuss their experiences in using the VR application were also used in this context [19,29]. The quantitative survey instruments used in the studies by Jung et al [19] and Groenveld et al [25] included both standardized questionnaires and assessments of physical performance. The questionnaires included the Chronic Respiratory Disease Questionnaire, Patient Health Questionnaire-9 [19], and the 11-point Borg Scale [25], as well as questionnaires regarding psychological and cognitive factors such as Generalized Anxiety Disorder-7 items [19], Hospital Anxiety and Depression Score, and Cognitive Failure Questionnaire [25]. Gabriel et al [23] further applied questionnaires to assess the usability of the application such as the System Usability Scale [23]. Notably, Groenveld et al [25] collected physical performance parameters. These include the 6-Minute Walk Test, Timed Up and Go Test, or 30-Second Chair to Stand Test. In addition, sensors such as smart bracelets (heart rate, pedometer, hand movements, sleep cycles) and pulse oximeters were used to measure the progress of therapy in the studies [27]. Overall, clinical outcomes (physical as well as psychological) and the evaluation of the application used in terms of acceptance and usability were analyzed in the studies.

Rehabilitation Program

The physiotherapy programs in the studies described in Table 2 primarily involve respiratory physiotherapy aimed at improving patients' functional ability [19,23-26,28,29].

Table 2. Characteristics of the rehabilitation programs evaluated in the studies included in this review.

Study, year	Type of training	Length of training	Setting of training	Virtual scenario
Gabriel et al [23], 2023	Physical training (pulmonary rehabilitation), educational content	Not reported	Home setting	Custom-made minigames and multiple choice
Gabriel et al [24], 2023	Physical training (pulmonary rehabilitation)	Not reported	Home setting	Custom-made minigames
Groenveld et al [25], 2022	Physical training, cognitive training, psychological exercises (meditation), independent training: self-management by patients	6-week trial	Home setting	Custom-made applications (minigames) for different exercises
Jung et al [19], 2020	Educational material, physical training (traditional pulmonary rehabilitation + focus on lower extremity), independent training: self-management by patients	8-week trial	Home setting, remotely supervised by health practitioners	Digital avatar
Lacko and Ruzický [26], 2022	Breathing exercises, physical training (upper limb), cognitive training	6-10 weeks	Diverse, remotely supervised by health practitioners	Digital avatar, photorealistic environments
Moorhouse et al [29], 2019	Physical training (pulmonary rehabilitation), educational material, independent training: self-management by patients	8-week trial	Home setting	Digital avatar
Ruzicky et al [27], 2022	Breathing exercises, physical training (upper limb)	Minimum of 3-4 weeks trial up to more than 5 months	Diverse, remotely supervised by health practitioners	Digital avatar, photorealistic environments
Smits et al [28], 2022	Physical training, cognitive training, psychological exercises (meditation), independent training: self-management by patients	6-week trial	Diverse	Custom-made applications (minigames) for different exercises

The focus of the studies was on various aspects such as relief of respiratory distress [19,23,24], rehabilitation of the upper limbs [26,27], and strengthening of the respiratory support muscles [19,29]. For this purpose, physiotherapeutic programs consisting of endurance, strength, and respiratory training were implemented. In addition, mental rehabilitation in light of the impact of the disease [28] as well as long-term goals such as feeling confident leaving the house [19] and quality of life [29] are addressed. Three studies also included exercises to improve cognitive skills [25,26,28]. Ruzicky et al [27] claimed that they addressed prevention, diagnosis, and treatment after COVID-19 but did not provide any further details on that. The length of the therapy programs ranged from 6 to 10 weeks [19,25,26,28,29]. Only in the study of Ruzicky et al [27], a minimum duration of 3-4 weeks was indicated, while in individual cases, the rehabilitation may last several months. In each case, the training program was designed for implementation in the home setting [19,23-29], but half of the publications also reported hybrid use cases within the study. For example, patients were able to try out the VR application in a therapy practice.

Moorhouse et al [29] as well as Jung et al [19], Smits et al [28], and Groenveld et al [25] implemented respiratory rehabilitation measures that were applied fully independently by patients. However, Ruzicky et al [27], Lacko and Ruzický [26], and Jung et al [19] implemented measures to monitor exercise progress. Patients were remotely assisted in setting up the program, for example, via telerehabilitation methods, while the exercises themselves were then performed independently [26,27]. Jung et al [19] focused on ensuring patient safety in their study on patients with COPD. For this reason, data such as heart rate and oxygen saturation were continuously measured in order to be able to intervene in the event of respiratory distress [19]. The selection of exercises was either defined by the patients themselves [29] or discussed with the therapist and adjusted to the requirements of the patients [26-28]. Ruzicky et al [27] and Lacko and Ruzický [26] specified that they included age, gender, and personality type in the selection process but did not specify what the criteria for the personality type is referring to and how age and gender influence the selection of the program.

The interdisciplinary research team consisting of researchers, medical doctors, physical therapists, designers, and VR developers as part of the study by Smits et al [28] developed a toolkit with resources and games. The program consisted mainly of pre-existing games and apps for physical, mental, and cognitive rehabilitation [28]. Three studies stated that a 3D avatar guides the exercises in the immersive VR environment [19,26,29]. Thereby, only 2 studies (from the same research team in Slovakia) chose a realistic representation of the avatar and environment [26,27]. Most commonly used VR headsets were Oculus Quest 2 [23,24,26,27] and Oculus Quest [25,28]. Other headsets used were Pico Interactive Goblin [19] and HTC VIVE Pro EYE [26]. Only Moorhouse et al [29] did not specify the headset used in their research.

Usability and Acceptance

VR-assisted digital respiratory rehabilitation was found to be generally acceptable and feasible in the reviewed studies. In this context, both the enabling factors and barriers for the development and implementation of corresponding applications could be derived from these studies. The benefits of virtual therapy include the aspects of immersion, motivation, as well as autonomy, flexibility, and the possibility of monitoring by therapists. In contrast, barriers include the initial adverse effects related to VR technology and the technical problems and lack of accessibility or usability of the VR applications.

Enabling Factors

In general, study participants described the tested applications as easy to use and enjoyable [19,23-25,28-30]. Studies in the context of respiratory rehabilitation of patients with COPD, in particular, also addressed the immersion in a virtual world, which among other things represents a distraction from the disease. In addition, the avatar guiding the exercises was considered as a social element to a certain extent [19,30]. VR is also considered easier to apply compared to traditional options such as instructions from printed material and booklets for the home environment [29]. Patients with COPD as well as patients with long COVID described the VR application as engaging and pleasurable [23,24,29]. They emphasized experiencing increased motivation to engage in therapeutic measures due to the stimulating or even calming nature of the virtual world, depending on the exercise [19,23-26,29,30]. The increased motivation leads to an increased frequency in usage [19,26,27]. Additionally, Smits et al [28] concluded that the gamification of exercises, in particular, contributes to the motivation of patients. Gamification refers to design elements that reproduce game elements and logics. This includes, for example, the integration of exercises into a game environment, earning scores through correct performance, and competitive approaches such as playing against each other.

Groenveld et al [25] distinguished between users according to their age and found that the duration of VR application increases with age. A possible explanation could be older persons' lesser familiarity with VR technologies because of which they are slower in navigating through the application and they lose interest in the interactive environment and the immersion less quickly [25]. Other studies reported patient groups without any previous experience with VR technology showing difficulties at the beginning of the program [26,27]. Lacko and Ruzický [26] and Ruzicky et al [27] also address the so-called "WOW-effect" in their study, describing first-time users' initial curiosity and great interest in VR [26,27]. However, according to this logic, boredom could also set in after a certain time of using the rehabilitation measure. In 2 studies, comments from study participants, including those who dropped out early, also indicated this same issue [25,26]. The digital program was described as boring, and doubts were expressed about the usefulness of the therapy [25].

Finally, the flexibility and autonomy in the implementation of VR therapy measures is emphasized in the reviewed studies [19,23,24,28,29]. This includes the feasibility of rehabilitation independent of time or location restrictions [23,24,28]. Jung et al [19] concluded that VR reduces the barriers for compliance by increasing the accessibility of rehabilitation programs, which are applicable in the home environment [19]. Patients mentioned that implementation in the home environment, in particular, can contribute to a feeling of comfort and security. In addition, patients reported that monitoring by therapists also gave them confidence [19,23,24]. Nevertheless, VR is perceived as a way to complement traditional therapies offering the advantage of social contact, which VR applications cannot fully compensate for [29].

All rehabilitation programs were customized for the patients in question. However, a distinction was made whether the program was determined by the therapist [19,26,27,29] or by the patients themselves [28]. Smits et al [28] also found that the ability to adapt the therapy to one's own level of rehabilitation and to select exercises individually offered a high added value and contributed to patients' autonomy. Likewise, Jung et al [19] and Moorhouse et al [29] corroborated the same findings in their evaluations.

Barriers

In addition to the benefits of VR-assisted respiratory therapy, barriers to VR implementation were described in these studies. First, the potential adverse effects of VR therapy are motion sickness or overextension due to immersion in an interactive virtual environment [25,28]. Motion sickness is a condition characterized by symptoms of nausea, vomiting, and dizziness caused by conflicting sensations related to motion. Motion sickness is commonly experienced when using VR devices, as the immersive nature of VR can create a sensory conflict between the visual input of a virtual environment and the lack of corresponding physical movement [31]. Further, dizziness, headache, or neck pain were among the most frequent reasons for patients to discontinue the studies [25,28]. Second, immersion can also cause anxiety through a realistic representation of an environment that does not match one's own setting. For example, some patients were afraid of falling while performing the exercises [28]. Third, the VR application was sometimes perceived as overwhelming [25,28]. Smits et al [28] stated the assumption that cognitive impairment as part of long/post-COVID condition may also make the use of VR difficult or impossible for certain patients. This also means that VR-assisted therapy programs should be used individually depending on the condition of each patient. Smits et al [28] therefore recommend a close physiotherapeutic supervision, tracking of training sessions, as well as the monitoring of vital signs. Furthermore, the headset was felt to be too heavy [19,23,29,30].

Studies with a focus on the technical user-friendliness of the application provided information on how to improve the tested applications [26,27,29]. These included, in particular, information on the navigation of the programs (ie, pause or fast forward button [29], one-click solution to start program [26,27]), which states that the technical accessibility and intuitive environment that allows handling even by less technically experienced people, are of great importance. In addition, some studies recommend providing the virtual environment with a simple graphical user interface [26,27] and using clear instructions [30] to facilitate use. Smits et al [28] point out that lack of usability can not only prevent usage and acceptance but also influence the results of studies aiming toward the evaluation of efficacy of programs. An appropriate design could also reduce the abovementioned adverse effects. Therefore, an interdisciplinary design process is recommended to ensure usability [28]. Furthermore, therapists will need proper training and logistical support in regard to the use and implementation of respective VR technology to adequately supervise the training of patients [28].

Clinical Outcomes

In addition to usability and acceptance assessments, all studies listed here also collected clinical parameters for the evaluation of respiratory rehabilitation. These included both physical and psychological outcomes. In regard to the respiratory function and fatigue, an overall improvement was reported in 3 studies [19,25,27]. Jung et al [19] reported that outcomes of female participants with regard to dyspnea and fatigue were even better than the results from male participants. In addition, a significant increase in patients' physical abilities such as strength and mobility was also observed [19,27-29]. Groenveld et al [25] found significant improvements in the 6-Minute Walk Test, grip strength, and 30-Second Chair to Stand Test. Ruzicky et al [27] mentioned that the program focused on developing upper limb mobility and cognitive skills through interactive tasks in the VR environment. However, information on the exact content of the tasks is lacking.

Surveys of the health-related quality of life and the Positive Health questionnaire and 12-Item Short Form Survey showed significant improvement in the quality of life in patients with COPD and patients with long COVID [19,25,29]. Patients felt fitter and were more likely to participate in social activities [19,29]. In the study of Groenveld et al [25], the improvement occurred already after 6 weeks. Further, stress and anxiety were reduced during the rehabilitation [19,25,29]. However, this was partly only true for patients who used specific mental health applications [25]. Participants also felt more confident in dealing with their own disease and in everyday tasks [19,28,29]. Some patients said that they were more mindful of their own health as a result of the program, making time for meditation on their own and setting preventive boundaries in their daily lives [28]. These experienced benefits of VR therapy as well as increased patient motivation also led to improved compliance [19,26-29].

Discussion

Principal Findings

The results of the reviewed studies show internationally available and initial evidence with regard to the development as well as the feasibility of respiratory VR rehabilitation for patients with long COVID in particular. The topic addressed in this review is a very new field of research. Approaches to VR therapy for other therapeutic needs such as for patients who had a stroke or Parkinson disease have already been implemented in the past 15 years [25,26,29]. However, lung-specific virtual physiotherapy appears to be still under development even in regard to the condition of COPD, which is already well-studied. The reported results are promising for VR applications, as the tested applications were described as enjoyable, pleasurable, and motivating when correctly introduced [19,23-27,29]. Furthermore, they can offer a more flexible rehabilitation program without restrictions of time and location [19,23,24,28,29]. Nevertheless, the studies also showed that the implementation of VR therapy interventions cannot generally be considered appropriate for every patient or in every setting because some patients could not complete the training due to motion sickness [25,28], and VR poses various hurdles in terms of the digital literacy of patients and therapists [23,24,28].

Comparison With Prior Work

A previous study that is the most similar to ours is the comprehensive review of VR for pulmonary rehabilitation by Pittara et al [32] in 2023. They offer a broader overview of VR applications in pulmonary rehabilitation by including all types of VR experiences, ranging from nonimmersive to fully immersive, and various populations, including healthy individuals as well as patients with COPD and asthma. In comparison to Pittara et al [32], our review takes a more focused approach by specifically filtering publications to include only immersive VR experiences within pulmonary rehabilitation programs for outpatients. The main strength of our review therefore lies in its clearly defined goals to provide an overview of immersive VR experiences for outpatients experiencing long COVID and COPD. Our review highlights the findings and shortcomings of existing research specifically in relation to the implementation of home-based rehabilitation programs for the target group. In particular, the hurdles of digital literacy identified for implementation at home and the need for training to ensure adequate use and guidance can be highlighted in this regard [27-29].

Our study findings also show the necessity to include the needs and prior knowledge of the target groups in the development of appropriate therapies. Only when appropriate programs achieve added value (eg, through individualized programs, monitoring) and are at the same time easily implemented, they can be applied in practice. The approaches adopted to involve patients in the evaluation of the applications, in terms of usability and acceptance, have shown that patients can provide important information for the development and implementation of VR-supported therapies [19,28,29].

Participatory approaches to technology development, which involve patients already during the development of applications and therapy programs, could help to adapt the applications even more precisely to the needs and requirements of users. The World Health Organization, for instance, recommends a patient-centered development of rehabilitation measures, digital services, and devices in order to support the self-care competence, especially of patients with long/post-COVID condition [4]. Regarding the novelty of the postacute condition, the involvement of patients seems even more crucial because researchers, practitioners, and patients are still undergoing a learning process on how to address and manage the symptoms reported [15]. Therapists, who are to integrate the applications into their therapy services and train the patients in their use, can also provide concrete information on their feasibility in practice. Of the studies analyzed in this review, however, only 1 study design included therapists [28].

Limitations

Although this scoping review was supported by steps, including refinement of the protocol through team discussion, blinded searching, and selection of papers by 3 researchers, several limitations have to be mentioned. First of all, limitations in the scope of the reported study results must be explained, as only 4 groups of researchers (from Slovakia, the Netherlands, United States, and United Kingdom) were involved in the studies analyzed, which represents quite a Eurocentric perspective. This scoping review was limited to studies published in English and German—the spoken languages of the researchers in this scoping review. However, the scoping review method and the explorative search strategy were deliberately chosen in order to be able to explore an overview of the topic while maintaining the focus of the research, and a critical evaluation of the studies was not intended. The second important aspect to note is that study designs implemented by the included studies and the quality in regard to scientific standards were very heterogeneous. Due to the diverse applied assessments and questionnaires, the comparability remains limited. Furthermore, evidence is still limited to pilot studies or a small number of patients, and no long-term studies or randomized controlled studies could be integrated—only cross-sectional surveys.

Conclusion

The results of this scoping review show that VR applications are well accepted by users, especially due to their flexible and individual applicability. Particularly mentioned by patients was the possibility of individualizing training plans and schedules as well as monitoring functions for remote monitoring by therapists. The implementation of rehabilitation measures in a playful, immersive setting contributed to motivating patients and increasing their compliance in respective studies. Initial feasibility studies also show an improvement in physical performance as well as psychological parameters such as confidence in managing the disease and quality of life. At the same time, hurdles arise with regard to the technical feasibility of VR therapies. Virtual applications must be as accessible and easy to use as possible so that patients without prior knowledge can also benefit from the therapy options. Furthermore, scientific research has to further develop empirical reliable findings for the sustainable long-term implementation of support programs for patients with long/post-COVID condition in the years ahead. In particular, the question on how to implement these findings into practice with regard to financing, further education of therapists, technical support, and the alignment of traditional and innovative autonomous approaches to therapy have to be a priority.

Abstract

Background: Mental health disorders are the leading cause of health-related problems worldwide. It is projected that mental health disorders will be the leading cause of morbidity among adults as the incidence rates of anxiety and depression grow worldwide. Recently, "extended reality" (XR), a general term covering virtual reality (VR), augmented reality (AR), and mixed reality (MR), is paving the way for the delivery of mental health care.

Objective: We aimed to investigate the adoption and implementation of XR technology used in interventions for mental disorders and to provide statistical analyses of the design, usage, and effectiveness of XR technology for mental health interventions with a worldwide demographic focus.

Methods: In this paper, we conducted a scoping review of the development and application of XR in the area of mental disorders. We performed a database search to identify relevant studies indexed in Google Scholar, PubMed, and the ACM Digital Library. A search period between August 2016 and December 2023 was defined to select papers related to the usage of VR, AR, and MR in a mental health context. The database search was performed with predefined queries, and a total of 831 papers were identified. Ten papers were identified through professional recommendation. Inclusion and exclusion criteria were designed and applied to ensure that only relevant studies were included in the literature review.

Results: We identified a total of 85 studies from 27 countries worldwide that used different types of VR, AR, and MR techniques for managing 14 types of mental disorders. By performing data analysis, we found that most of the studies focused on high-income countries, such as the United States (n=14, 16.47%) and Germany (n=12, 14.12%). None of the studies were for African countries. The majority of papers reported that XR techniques lead to a significant reduction in symptoms of anxiety or depression. The majority of studies were published in 2021 (n=26, 30.59%). This could indicate that mental disorder intervention received higher attention when COVID-19 emerged. Most studies (n=65, 76.47%) focused on a population in the age range of 18-65 years, while few studies (n=2, 3.35%) focused on teenagers (ie, subjects in the age range of 10-19 years). In addition, more studies were conducted experimentally (n=67, 78.82%) rather than by using analytical and modeling approaches (n=8, 9.41%). This shows that there is a rapid development of XR technology for mental health care. Furthermore, these studies showed that XR technology can effectively be used for evaluating mental disorders in a similar or better way that conventional approaches.

Conclusions: In this scoping review, we studied the adoption and implementation of XR technology for mental disorder care. Our review shows that XR treatment yields high patient satisfaction, and follow-up assessments show significant improvement with large effect sizes. Moreover, the studies adopted unique designs that were set up to record and analyze the symptoms reported by their participants. This review may aid future research and development of various XR mechanisms for differentiated mental disorder procedures.

extended reality; mental disorder; depression; anxiety; exposure therapy

Introduction

Background

Mental disorders are defined as behavioral or mental patterns that cause significant distress or impairment for an individual. These are highly prevalent and, currently, are the leading cause of disability worldwide. In the past decades, a worldwide increase in the incidence of mental disorders has been observed [1,2]. According to the World Health Organization (WHO), mental disorders are the leading cause of disability in the United States and the United Kingdom. The WHO predicted that mental disorders would account for 13% of the total burden of diseases by 2030 [3]. As an indication, around 20% of adults experience 1 type of mental health problem in the United States, the United Kingdom, and related high-income countries [4]. A recent survey shows that the acceleration of socioeconomic developments has increased the prevalence of mental disorders (17.5% adults) in China [5]. Meanwhile, adolescents are characterized with the highest incidence of mental disorders in Canada [6]. Although over 75% of people with mental disorders remain untreated in middle-income countries, 35%-50% of the corresponding range is also found in high-income countries [3].

The WHO estimated that these mental conditions will cost the worldwide economy about US $1 trillion in lost productivity annually [7]. Some of the mental disorders are interlinked. For instance, anxiety and depression remain the most common mental disorders in society [8]. Anxiety is closely linked to mood disorders, and individuals developing depression have often experienced anxiety disorder at some earlier point(s) in life [9]. Although the etiology of anxiety disorder and depression is complex, multiple causal factors, such as rapid social change, stressful work conditions, gender discrimination, social exclusion, an unhealthy lifestyle, physical ill health, human rights violations, and genetics, have been appropriately studied. Many times, mental health researchers have studied the positive effects of evaluating anxiety in combination with other mental conditions, such as pain and depression. For example, Bandelow and Michaelis [10] reported that 1 of every 13 mental disorders is anxiety with major depressive and specific phobia disorder. In general, reports mostly suggest that closer mental care should be addressed by increasing the accessibility and development of tools that patients can use on their own [3].

Conventional Assessment Approaches

Cognitive behavioral therapy (CBT) is a conventional approach that is shown to be effective in the treatment of a wide range of mental disorders, such as anxiety disorder, depression, phobia, and alcohol use problems [11]. CBT is based on the core principle that thoughts impact feelings and feelings impact behavior. During CBT, patients learn to change maladaptive thinking patterns and novel coping behaviors to become and stay healthy. CBT can be as effective as, or even more effective than, other forms of psychological therapy or even psychiatric medications, especially for patients diagnosed with anxiety disorder or depression. CBT is well supported by many clinical practice guidelines [11]. Studies have shown that it is an evidence-based therapy that reliably helps in overcoming depression. However, it involves aiding people to identify and change the bad lifestyles that negatively influence their behavior and emotions [12]. Rather than being a set method, CBT combines procedures that are developed on a certain disorder that has been unevaluated. For instance, the treatment procedure for depression is different from how CBT is used in evaluating phobia and anxiety disorder.

Exposure therapy is a major element of CBT that is more focused on certain mental disorders related to anxiety [13]. In this approach, participants, the subjects being assessed, are exposed to feared objects, activities, or situations in a safe environment, and this is known to reduce patients' fear and possibility of avoidance. With gradual follow-up, participants learn to overcome their anxiety [14]. The variations of exposure therapy can be majorly classified as conventional exposure and modern exposure, usually based on the application context. Conventional exposure includes both in vivo and imaginal exposure. During in vivo exposure, patients are intentionally faced with real-world objects or situations they fear to reduce their anxiety [15]; however, it only works in a small percentage of mental health cases. In contrast, imaginal exposure configures an alternative approach during which patients imagine the worst outcome scenarios to confront their fears within their mind. The effectiveness of imaginal exposure depends on a patient's motivation and their ability to generate fear-inducing imaginations. Exposure therapy is challenging as therapists require extensive training and multiple, long exposure sessions. Consequently, the conventional methods are time-consuming and costly. Recently, XR was evaluated as a new approach for delivering exposure-based therapy for mental disorders. The potential of XR for treating anxiety and depression has been reported [16,17].

Use of Extended Reality in Mental Health

"Extended reality" (XR) is an umbrella term referring to all real, virtual, and mixed environments, wherein interactions are generated by computer technology to engage humans [13]. XR is a rapidly growing technology and is playing prominent roles in different sectors, such as providing clear benefits in many aspects of work and business, including training, collaborative working, and marketing. The technology is rapidly gaining traction in creating imagination of real worlds through virtual reality (VR), augmented reality (AR), and mixed reality (MR). XR was recently conceived for carrying out the evaluation of mental health. Thus, patients with mental disorders can be virtually immersed to allow them to display and confront the disorders they have. It has been noted that the advances in XR tools can transform the health domain remarkably; however, an exciting issue is studying the adoption and implementation levels of current VR, AR, and MR techniques for evaluating mental health [18-20]. In the industry sector, reports showed that the XR medical market was estimated to reach US $1.7 billion in 2022, with a compound annual growth rate of 105.6% from 2018 to 2022 [21]. Thus, supporting XR-based solutions will play a crucial role in the future of mental health. As the market continues to grow, it is safe to assume that developing XR technologies for mental disorder interventions will continue to increase.

In mental health interventions, XR techniques involve the use of single or multiple base technologies to create exposure. The base technologies, namely VR, AR, and MR, involve using computer models to artificially design real-world environments with stimuli sensory features. Thus, the artificial environment can simulate typical contexts that induce mental disorders, such as anxiety, phobia, or pain, to enable users to interact with the environment. Typically, an artificial environment can be developed using 4 main components:

- A high-end graphics-rendering unit that is used to compute and render virtual scenes via a frame buffer
- A 3D stereo display unit that connects users' visual sensory system to the environment
- A tracking system that models users' movement in the virtual environment
- Other input interfaces, such as joysticks or sensory gloves, that provide tactile feedback

Currently, studies suggest that XR-based evaluations can be as effective as conventional exposure–based methods [11,22-24]. It is anticipated that XR technology will offer the greatest promise for mental health care [11]. This is because XR-based exposure therapies are found to be accessible and can offer lasting improvements for different mental health conditions. By analyzing many studies, we have found that a good number of XR techniques exist. These are used to evaluate different mental disorders via different software and hardware technologies [11,22,25,26]. XR systems have been successfully applied in individual, group-based, and internet-based mental health interventions [27-29]. The adoption of XR systems started around 2 decades ago, when Hoffman and coworkers [30] developed a VR gaming system called *SnowWorld* for exposure-based therapy in mental health care. The game provides a systematic way of reducing players' pain perception during burn wound care. Anderson et al [22] presented a follow-up of the first randomized clinical trial to test another format for delivering CBT for social anxiety disorder—VR exposure therapy. The study showed that VR and exposure group therapy has been well established as an effective strategy for evaluating social anxiety disorder.

The application of XR technologies (VR, AR, MR) for mental health care delivery provides opportunities and a greater degree of control for therapists to customize, reproduce, and tweak several evaluation parameters according to an individual patient's needs during mental health care. Such parameters include fan wind, stereo sound, a moving chair, a color display, and odor emitters [31]. This kind of customization may not be achieved in traditional exposure therapy [32,33]. In addition, the risks associated with privacy intrusion reduce as everything is transformed into a virtual environment [34]. Simulated and augmented environments are less scary than the use of in vivo and imaginal exposure in conventional therapy [30]. Exposure-based therapies defined on VR/AR/MR apps have been shown to be effective for evaluating different mental health conditions. This study presents the findings of a scoping review of the state-of-the-art XR systems used in mental health care.

Objective

XR-based mental health interventions have been advancing rapidly. It is critical to analyze the implementation and adoption levels of state-of-the-art XR techniques (ie, a combination of studies that have reported VR, AR, and MR) used for mental health care delivery. This review was conducted following the guidelines outlined by Arksey and O'Malley [35]. The main objective of this scoping review was to show the implementation and usage levels of XR-based therapy in providing care for different mental disorders worldwide. Thus, this review was set to provide a statistical analysis of studies that have recently focused on (1) technological design and usage of XR in mental health care with a worldwide demographic focus, (2) components that are found in different XR interventions used for mental disorders, and (3) effectiveness of XR technology in anxiety and depression as top mental disorders.

Methods

Eligibility Criteria

The adoption of VR, AR, and MR for mental disorder evaluation has evolved over time. The rapid advancement has occurred in a corresponding timeline with developments in the hardware and software used for implementing XR technologies. Hence, we decided to limit our data sources to papers published between August 2016 and December 2023 so as to analyze the state of the art in the study area. Advance search sections of 3 databases by the authors OM, IO, JO, and AB individually and the papers located were later combined to ensure a wide coverage of papers published in the search period. Further, only a limited set of search criteria were used to limit the papers extracted to more relevant ones. We only considered studies that were published in peer-reviewed journals and refereed conferences (with oral presentations). Ten records were identified via professional sourcing. Based on our search strategy and study goal, we decided to use a combination of 2 search rules: (1) all search terms must be present in the paper's title or abstract or both, and (2) the paper's publication year must be within the specified range between August 2016 and December 2023. Additionally, exclusion criteria were defined as (1) duplicate papers; (2) version updates; (3) papers written in a language other than English; (4) studies that reported anxiety or depression as a secondary aspect or induced illness; and (5) papers presenting strengths, weaknesses, opportunities, threats (SWOT) analysis, thesis and citations, and scoping reviews.

Information Sources

We formulated a search strategy used to explore multiple databases to find all recent and relevant studies on XR technologies. We focused on information from studies that focused on depression and anxiety and related mental disorders. The scoping search was conducted on 3 different databases that are library sources for research papers, gray literature, patents, and common information. Our choices of databases were (1) PubMed, (2) Google Scholar, and (3) the ACM Digital Library. These databases were chosen because they provide an interface to generate wild search queries across a variety of disciplines, databases, and journals. In addition, they have the most complete indexes of papers that focus on the theme of this review study. This aided us in simultaneously accessing a broad range of evidence, including technical and peer-reviewed studies reported from different parts of the world, different publishers, and over a long period. We defined our search period to filter out only papers published between August 2016 and December 2023 and indexed in any of the 3 databases. Overlapping papers were filtered to avoid duplication. Multilevel filtering was carried out following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [35] and the associated checklist in Multimedia Appendix 1. This limited the search outcomes to relevant studies that could provide the most valuable data to answer our research objective. The search strategy was set to limit data sources to studies that implemented or used VR, AR, or MR for different mental disorders.

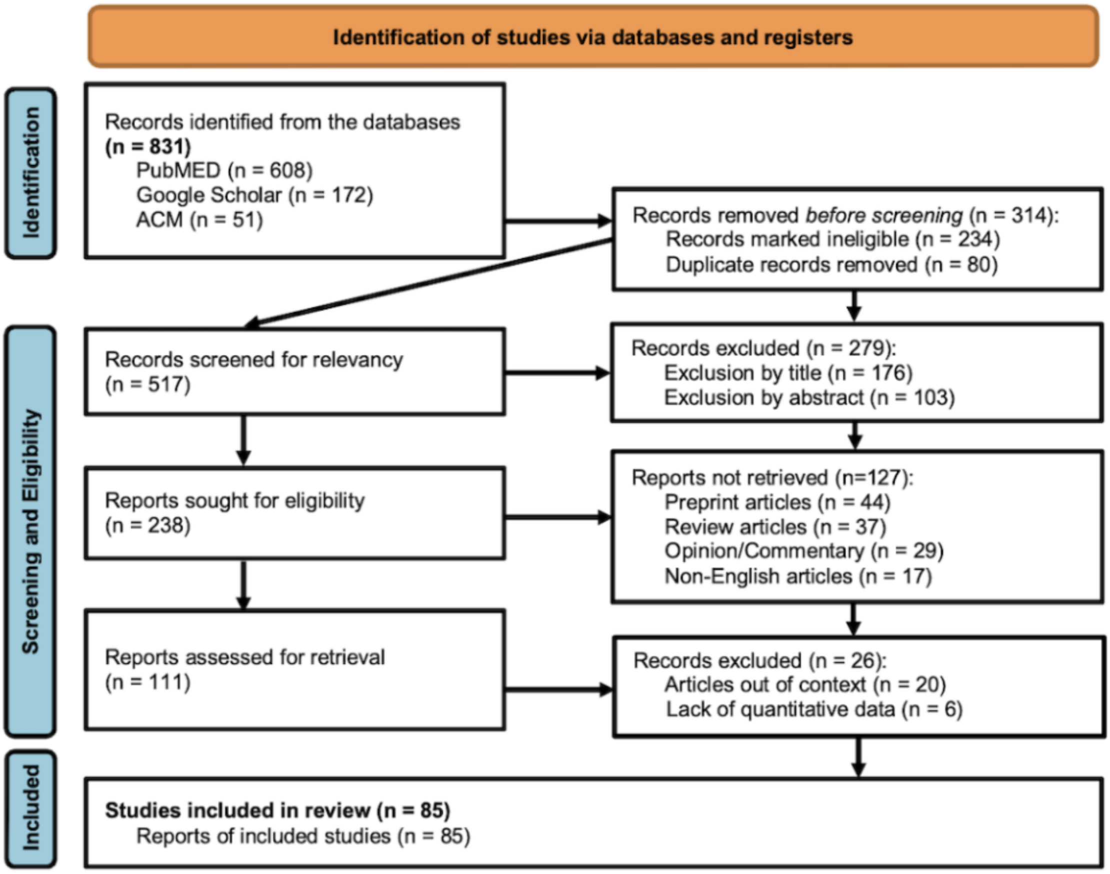
Search Strategy

Our paper search strategy was based on using an organized structure of search terms to retrieve the existing literature in the 3 databases. We combined the keywords in our research objective in order to retrieve relevant papers from the databases. The search terms were discussed among the research team members and were defined as "augmented reality," "mixed reality," "virtual reality," "depression," "anxiety," and "mental health." We chose the free-text search as it is more flexible, and targeting the free words in both the title and abstract fields to limit the final sets provided an efficient way to increase the specificity of our search. These keyword searches were carried out for each concept in our research objective, and we designed the search queries to include a combination of the Boolean operators "OR" and "AND" to reduce the omission of vital papers. These search terms were the most appropriate keywords that were reflected in the subject area and had the utmost relevance to our review objective. We exclusively used full terms during the search in order to avoid any potential conflicts with other terms; for example, VR for "virtual reality" might also be used for "voice recognition," which would make the filtering cumbersome and not necessarily generate additional useful resources. The selection criteria were carefully designed to consider papers that contained 1 or multiple search terms in the their title or abstract or both.

Study Selection

The search yielded 831 papers scraped from the 3 databases, and 10 papers were identified through a professional source. Specifically, by using the defined search filter criteria "anywhere in the article," the search results included 608 (73.16%), 172 (20.7%), and 51 (6.14%) papers scraped from PubMed, Google Scholar, and the ACM Digital Library, respectively. The papers were scraped and processed by following the set of items in the PRISMA checklist. First, authors IO, JO, and AB independently screened the papers retrieved, while author OM performed a quality check on all the final records. Next, irrelevant and duplicate papers (314/831, 37.79%) were removed; thus, a total number of 517 (61.47%) papers were left. The remaining papers were further screened for relevance. With title screening, 176 (30.04%) irrelevant papers were removed. Full abstract reviews was performed in situations in which a paper's relevance could not be resolved from its title. Thus, 103 (58.52%) papers were further screened out. Yet, authors carried out a review of the full text when certainty on a paper's relevance was still lacking in order to decide whether it was relevant. In total, 279 (53.97%) nonrelevant papers were screened out by the authors, leaving only 238 (46.03%) papers for retrieval. A second screening step was required to limit the scoping review to papers that fulfilled the eligibility criteria. Thus, further assessment was carried out, and another 127 (53.36%) papers were removed. The full texts of the remaining 111 (46.64%) papers were retrieved. Papers that were out of context (n=20, 18.02%) and those that lacked quantitative data (n=6, 5.4%) were also excluded. Finally, a total of 85 (76.58%) papers that meet the eligibility criteria were included in this review. All these procedures were performed in Microsoft Excel and without any form of automation. The paper selection process strictly followed the steps shown in Figure 1.

Figure 1. Literature screening and selection flowchart following PRISMA guidelines. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Data Collection and Information Extraction

Three of the authors performed data extraction, while data validity and accuracy were checked by a fourth author. The full texts of the 85 papers were downloaded and shared among the authors for review. The following specific details of the papers were extracted and processed in Excel to analyze the adoption of VR, AR, and MR in managing anxiety and depression and related mental disorders:

- Authors, year, and regions
- The study type and study design focus and health domain
- the methodology (eg, study duration, number of sessions, and duration in minutes)
- The methodology that the study was based on and the evaluation strategy
- The VR/AR/MR app and technology (eg, type of headset, toolkit) used for the study
- Study demographics, such as targeted population, sample size, and age distribution
- Motivational strategies, targeted outcome, and region
- Key findings on using the XR techniques for managing depression and anxiety

The details related to the abovementioned data were used to address the specific research objective guiding this scoping review. The useful insights provided by the data could help developers and researchers on future research on VR/AR/MR for the intervention of mental disorders. In addition, users can learn the importance of such systems, such as the use of XR-based exposure therapy, for mental health.

Results

Publications' Demographics by Country and Year

This scoping review was based on a total of 85 papers [26,32,36-118], which are described in Multimedia Appendix 2. We reported the statistics and meta-analysis of studies that addressed the technological design and usage of XR in mental health, the major components used in different XR interventions for the management of mental disorders, and the effectiveness of the XR technology in anxiety and depression as top mental disorders.

First, we analyzed the country of origin of the papers. The 85 studies were conducted in 27 countries worldwide, as presented in Table 1. Of these 85 studies, 14 (16.47%) were carried out in the United States, followed by 11 (12.94%) in Germany. Compared to a previous study [12], both countries dedicated a good amount of research funding and time to study how XR aids mental health care in the United States and Germany. The data also showed that a good number of studies were conducted in South Korea (n=8, 9.41%) and the Netherlands (n=6, 7.06%). Our study infers that compared to the remaining 21 countries, the aforementioned 4 countries invested a good amount of effort in domestic technological development toward creating XR-based tools for mental disorder. Thus, XR systems contribute immensely to the economic and health care systems of high-income countries. Meanwhile, our data also identified that mental studies are not yet prioritized in Africa. In terms of study frequency by year, Table 2 shows that the majority of papers (n=27, 31.76%) were published in 2021. This could underline a worldwide priority set to advance mental health care. However, none of the studies mentioned whether this was attributed to the ongoing COVID-19 pandemic [119]. Nonetheless, secondary studies identified that the prevalence of anxiety and depression increased by 25% in the first year of the pandemic, while the psychosocial effects of the pandemic varied by regions [120,121]. Hence, it is likely that the pandemic-related increase in mental disorders and the increased adoption of virtual treatment during the pandemic contributed to the rise in the number of XR-based mental health interventions in 2021. Furthermore, there was a great decline in the number of investigations reported in 2022 (n=12, 14.12%) and 2023 (n=16, 18.82%). This coincides with the time COVID-19's worldwide prevalence had decreased.

Table 1. List of countries that conducted mental health studies using XR[a] technologies.

Number	Country of study	Studies (N=85), n (%)
1	Armenia	1 (1.18)
2	Australia	2 (2.35)
3	Austria	2 (2.35)
4	Belgium	1 (1.18)
5	Canada	1 (1.18)
6	China	4 (4.71)
7	Denmark	2 (2.35)
8	France	1 (1.18)
9	Germany	11 (12.94)
10	Hong Kong	1 (1.18)
11	India	1 (1.18)
12	Iran	3 (3.53)
13	Israel	2 (2.35)
14	Japan	1 (1.18)
15	Jordan	2 (2.35)
16	South Korea	8 (9.41)
17	Netherland	6 (7.06)
18	Philippines	1 (1.18)
19	Poland	2 (2.35)
20	Portugal	2 (2.35)
21	Romania	2 (2.35)
22	Singapore	1 (1.18)
23	Spain	7 (8.24)
24	Sweden	2 (2.35)
25	Turkey	1 (1.18)
26	United Kingdom	4 (4.71)
27	United States	14 (16.47)

[a]XR: extended reality.

Table 2. Number of studies published per year.

Year of study	Studies (N=85), n (%)
2016	3 (3.53)
2017	8 (9.41)
2018	4 (4.71)
2019	8 (9.41)
2020	7 (8.24)
2021	27 (31.76)
2022	12 (14.12)
2023	16 (18.82)

Demographics of XR Usage: Age Population

We analyzed the age of the participants included in the studies and categorized the participants as *children*, *teenagers*, *adolescents*, *young adults*, *young and old adults*, and *old adults* based on the age ranges reported in the 85 studies included in this review. Studies that omitted such information were declared as *not specified*. A substantial age overlap was found among the groups of individuals included in the reviewed studies. Thus, *adults* were taken as participants between 18 and 65 years old in the reported studies, and *older adults* were above 65 years old. We observed that around half of the studies (n=38, 44.71%) were designed for adults (between 18 and 65 years old). However, a small number of studies focused on younger age groups: 10 (11.76%) of the 85 studies focused on participants between 0 and 12 years old, while 2 (2.35%) focused on participants in their teenage years as well. The poor representation of participants from each age group in the reviewed studies could be due to a lack of a standardized way of selecting a target audience when developing XR systems for managing mental disorders [122].

In Table 3, we indicated the common classification of participants' age ranges reported in the selected studies, in addition to the statistical information derived from the age groups. This is because the age ranges used for defining the categories of participants in the 85 papers were not unique. In addition, there was great overlap when comparing the categories and age ranges across studies. Thus, we refined the data to synthesize the mean age distribution of the participants included in each study. For this, the age ranges were set as given or generated as (mean – SD) to (mean + SD), when only the mean (SD) was given. The mean age distributions of the participants used for classification are reported in Table 3. The data indicated that the majority of studies (n=47, 55.29%) were designed for an audience with a mean age of 35.079 (SD 9.72) years. The age distribution in this group was particularly dominated with lower and upper values of 18 years (26/47, 55.32%) and 65 years (7/47, 14.89%), respectively, in the different participants' age ranges. The age range of the youngest participants who participated in an XR-based study on mental disorder [58] that investigated how VR reduces the perception of anxiety in infants were a group of children 4-8 years old.

Table 3. Table3. Participant categories found in the included studies by level of maturity.

Participant categories	Studies (N=85), n (%)
Audience group	
Children	10 (11.76)
Teenagers	2 (2.35)
Adolescents	27 (31.76)
Adults	38 (44.71)
Older adults	3 (3.53)
Not specified	5 (5.88)
Age range (years)	
1-10	23 (27.06)
11-20	47 (55.29)
21-60	7 (8.24)
61-85	1 (1.18)
≥85	2 (2.35)
Not specified	5 (5.88)
Participants enrolled	
1-10	10 (11.76)
11-20	9 (10.59)
21-50	23 (27.06)
51-100	22 (25.88)
>100	16 (18.82)
Not specified	5 (5.88)

Demographics of XR Usage: Study Sample Size

We analyzed the sample size of participants enrolled in the 85 studies included in this scoping review. We divided the sample size into 5 different categories and analyzed the number of studies, as reported in Table 3. It can be seen that most studies recruited 51-100 participants (n=22, 25.88%). Next came studies that recruited 21-50 participants (n=23, 27.06%) to evaluate mental health care with XR. Furthermore, 16 (18.82%) studies included over 100 participants, while a small sample size (≤20 participants) was considered in 19 (22.35%) of the 85 studies. Most of these 19 studies were more subtle in their findings and conclusions. Thus, it can be understood that having relatively more participants is helpful to reach better conclusions. Overall, each of the participant categories identified was reported in at least 5 (5.88%) different studies. It is worth mentioning that only 5 (5.88%) studies did not specify the sample size used. The participants' gender distributions were not analyzed, as these data were missing in most studies included in this scoping review.

Demographics of Design and Implementation Strategies

The application of XR systems for mental disorders requires vigorous study and implementation strategies. We analyzed different factors usually considered when designing or evaluating XR systems for mental health interventions. The 3 major considerations found in the 85 selected studies were the *type* of study performed, *design* factors, and the *evaluation method* used to assess each study. With a focus on anxiety and depression, the 4 main types of studies that were are carried out were (1) *discussions*, which are studies with a narrative focus; (2) *experimental*, which are studies that are conducted to investigate the effect of XR techniques on certain groups of subjects or other factors that aid or affect such a setup; (3) *modeling*, which are studies that are conducted to develop new models or setups and validate these on limited subjects or data; and, lastly, (4) *analysis*, which are studies performed without any particular experimental study but relying on the data of previous *experimental* studies.

As reported in Table 4, it was found that 67 (78.82%) of the 85 studies investigated experimentally to report how XR aids in interventions for mental disorders. Meanwhile, 8 (9.41%) studies were based on modeling and analysis each, while 1 (1.18%) study was based on narration (ie, discussion). This shows that most studies were conducted as experimental investigations. Typically, this enabled a direct comparison between mental conditions and their relationships with their causal factors in psychological cornerstone studies [123]. Furthermore, 50 (58.82%) studies investigated the effects of XR immersion. This shows that researchers in this domain are commonly fond of investigating how immersion can influence mental health care procedures. The other design factors of the XR systems found in the 85 studies were on the subject's process automation (n=14, 16.47%); these studies were majorly investigated to observe whether they well emulated real-world situations and environments. Similarly, 9 (10.59%) and 6 (7.06%) studies typically focused on cases of XR personalization and manual execution, respectively.

Table 4. Demographics of the study implementation factors.

Participant categories	Studies (N=85), n (%)
Type of study	
Discussion	1 (1.18)
Experimental	67 (78.82)
Modeling	8 (9.41)
Analysis	8 (9.41)
Design factor	
Personalization	9 (10.59)
Manual	6 (7.06)
Process automation	14 (16.47)
Immersion analysis	50 (58.82)
Evaluation method	
Quantitative method	32 (37.65)
Qualitative method	26 (30.59)
Mixed method	23 (27.06)
Not specified	4 (4.71)

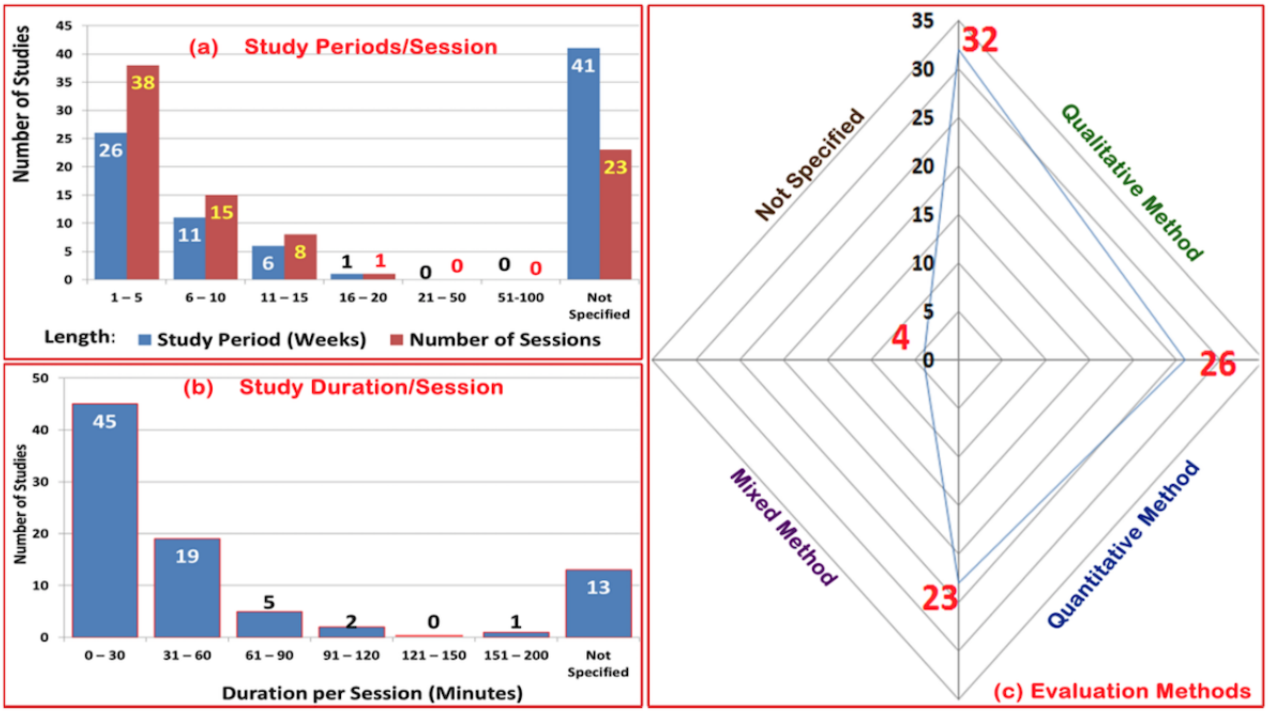
Relationship Between Study Periods and Duration per Session

Next, we analyzed the common evaluation categories reported in the 85 studies. First, categories of study periods (in weeks) and the duration per session (in minutes) were analyzed with respect to the number of sessions in each study. As presented in Figure 2a, some of the studies (n=27, 31.76%) were carried out in 1-5 weeks, 7 (8.24%) studies lasted for 6-10 weeks, and 8 (9.41%) studies lasted for 11-15 weeks . It is worth emphasizing that the longest study (n=1, 1.18%) lasted for 16-20 weeks. In addition, 39 (45.88%) studies evaluated their participants in 1-5 sessions, while 15 (17.65%) studies evaluated their participants in 6-10 sessions.

Furthermore, we analyzed the duration per session (in minutes) for sessions that were reported in each study. In more than half of the studies (n=44, 51.76%), participants used XR techniques for 0-30 minutes, followed by studies requiring 31-60 minutes (n=19, 22.35%) and 61-90 minutes (n=5, 5.88%) of user engagement per session. On the extreme end, the XR technique was used for a single session that lasted over 100 minutes in 4 (4.71%) studies. It was also observed that 13 (15.29%) studies did not specify session durations.

In addition, we analyzed the common evaluation method used in the 85 studies included in this review, and identified 3 main methods: quantitative, qualitative, and mixed. The qualitative assessment approach was applied in 31 (36.47%) of the 85 studies, and it was understood that the qualitative method reveals deeper insights into XR-based evaluation. Furthermore, the quantitative method was used in 9 (10.59%) studies, while the mixed methods approach was used in 18 (21.17%) studies. We also found that 2 (2.35%) studies did not report evaluation methods (see Figure 2c).

Figure 2. Categories of studies included in this review.



Extended Reality and Gamification Strategies for Mental Disorders

It is important to analyze the XR techniques used in interventions for depression and anxiety. First, we analyzed the major strategies found in the 85 studies included in this review. The XR tools used in each study were identified to be either gamified or nongamified. Gamification strategies were adopted in 26 (30.59%) studies, and these strategies were used across 10 mental disorders in all 85 papers. The few exceptions where a gamification strategy was not applied included negative thoughts, panic disorder, and pain and anxiety. Conversely, nongamified strategies were adopted in interventions for the remaining mental conditions, accounting for 59 (69.41%) of the 85 studies. However, alcohol use disorder and attachment behavior were only addressed using gamified XR systems. It may be right to think that gamification strategies are yet to mature for such conditions or, possibly, that existing gamification strategies are not suitable when evaluating such mental disorders using XR techniques or, perhaps, there are ongoing studies to show their applicability.

Extended Reality Development Tools

We also analyzed XR apps that were used in the 85 studies and found that specific systems, such as 3D Unity Pro, are commonly used by many authors in the development of XR systems. Only 68 (77.64%) of the 85 studies reported the name of the actual XR app they implemented or adopted. As reported in Table 5, the most frequently used tool for developing XR platforms was 3D Unity Pro (n=16, 23.53%). This is probably due to its powerful editor to create XR systems and its support for cross-platform development. Similarly, we observed that some studies (n=15, 22.06%) were carried out with custom VR systems. Such adaptive apps are either newly developed or adopted and evaluated for aiding mental health care. Meanwhile, Blender 3D and mobile virtual systems were used in 3 (4.41%) and 10 (14.71%) studies, respectively. Another 24 (28.24%) studies indicated using a development platform but did not specify it, while the remaining 17 (20%) studies did not mention the use of any development platform.

Table 5. Software VR[a] tools commonly used for XR[b] development.

XR app	Studies (N=85), n (%)
3D Unity Pro	16 (18.82)
Custom adaptive VR software	15 (17.64)
Blender 3D	3 (3.52)
Mobile virtual system	10 (11.76)
Others	24 (28.24)

Hardware Technologies Used for XR in Mental Disorders

To further fulfill the aim of this study, we extracted information about the XR technologies used to deliver mental health care in the 85 studies. To be as inclusive as possible, we only reported the hardware components that were listed for setting up the XR environments in the studies (Table 6). The use of headsets was consistent in 46 (54.11%) of the 85 studies; thus, headsets are the most commonly used component when setting up XR for mental disorder interventions. Typically, it was found that the Oculus head-mounted display (HMD) and VR headsets were common in such studies. In addition, smartphones are a common technology used in setting up the XR environment. It was found that 7 (8.24%) studies included smartphones of different types. These hardware components (ie, HMDs, smartphones, and VR glasses) were increasingly popular in studies where the gamification strategy was adopted. We further analyzed the most popular types of headsets and found that they were headphones, earbuds, and VR HMDs. These last are a more advanced technology and a basic component in most XR studies. As reported in Table 7, there were 9 different types of HMDs used in the 85 studies. HTC Vive and Samsung Gear VR were the most used HMDs in setting up XR systems: these were found in 12 (14.12%) and 11 (12.94%) studies, respectively. The next such HMD was 3D VR glasses, which were used in 7 (8.24%) studies. In addition, Oculus Go and Google VR Box were used in 3 (3.53%) studies each; 2 (2.35%) papers reported to have used Oculus Rift; and different types of VR simulators, such as Oculus CV1, a custom electroencephalography (EEG) cap with a VR HMD, and the Windows MR headset were also used in 1 (1.18%) study each.

Table 6. Types of hardware technology used in XR[a] interventions for mental disorders.

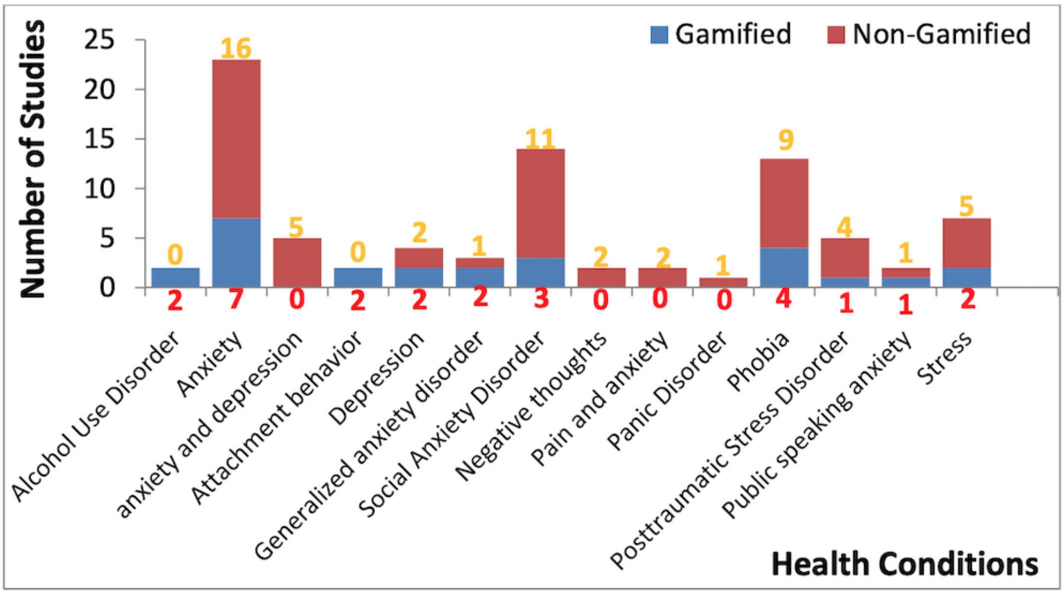
Extended Reality for Anxiety and Depressive Disorders

We identified 14 types of mental disorders in the 85 papers and illustrated the number of studies investigating each condition, as shown in Figure 3. We observed that most of the XR studies were centered around anxiety and depression (n=53, 62.35%). These included the use of XR for anxiety without depression in 43 (52.94%) studies, where the primary and secondary focus included anxiety, and depression was not considered at all. In 4 (4.71%) studies, we found that minimal attention was on depression, wherein anxiety of any kind was not considered. Typically, 23 (27.05%) studies focused on just anxiety, while the remaining 30 (35.29%) studies combined anxiety with other mental disorders. Anxiety and depressive disorders sometimes have ambiguous borderline definitions; thus, this scoping review focused more on them. We further looked into individual conditions, such as social anxiety disorder and generalized anxiety disorder, which were found in 14 (16.47%) and 3 (3.53%) studies, respectively. These conditions were combined with unclassified distress in 2 (2.35%) studies [66,79]. Of the 85 papers included in this review, 13 (15.29%) were found to have applied XR technologies for phobia-related mental disorders (fear disorders that are a clinical evaluation of anxiety).

Figure 3. Number of studies per clinical condition.



The adoption of XR for mental disorders without anxiety or depression was also studied. For instance, physiological disorders, such as emotion and stress issues, were investigated. Among these, phobias of different kinds (eg, acrophobia, claustrophobia, fear) were investigated in 13 (15.29%) of the 85 studies, and posttraumatic stress disorder was studied in 5 (5.88%) papers. The latter has a similar frequency as 1 of the top mental disorders, depression. We also found that negative thoughts and attachment behavior were investigated in 2 (2.35%) studies each. In contrast to Baghaei et al's [124] findings, we found that generalized anxiety disorder was investigated as a specific clinical condition in 3 (3.53%) studies. In addition, other mental disorders, such as alcoholic use disorder, attention disorder, attachment behavior, negative thoughts, pain and anxiety, and public speaking anxiety, were found in only 2 (2.35%) studies, while panic disorder was found in only 1 (1.18%) study. Thus, XR technology is commonly used for evaluating anxiety disorder. Finally, this scoping study shows that XR-based evaluations are distinctly applied for anxiety and other mental disorders that exclude depression. A typical case includes the development of an XR system for anxiety and phobia, as well as anxiety and psychiatric disorders [16,87]. The benefits of XR for the evaluation and management of mental disorders were identified in the 85 papers that were reviewed. Recent studies show that VR yields the same level of effectiveness as exposure-based therapy for reducing anxiety symptoms [125]. This section mostly uncovered the use of VR technology in anxiety; however, it showed that AR and MR have been recently emphasized as an add-on technology and not a substitute. It is clear that more studies are still needed for evaluating how AR and MR can singly improve mental health.

Discussion

Principal Findings

In the previous section, we focused on the demographics, technologies, and study designs found in existing XR systems used in mental disorder interventions. In this section, the effectiveness of the XR systems for anxiety and depression as top mental disorders are analyzed, as reported in the 85 studies [26,32,36-118] included in this review.

Effectiveness of XR Technology for Mental Disorder Intervention

Following the review of the literature included in this scoping study, it can be concluded that XR systems are commonly used for managing mental disorders. In this scoping review, we found that XR technologies have been majorly used for evaluating anxiety and depression separately, in combination with each other or with other common mental disorders. In the latter case, the majority of studies were targeted at cognitive and behavioral change (ie, subjective care) to improve patients' behavior or attitude or both. In addition, it was observed that among XR technologies, VR-based systems are mostly used. For instance, in some studies [26,77,82], VR was effectively used to evaluate anxiety and depressive symptoms in patients with mental disorders. Similarly, Li and Luo [84] established that gamified XR can reduce depressive disorders through cognitive empathy and mutual understanding among patients and caregivers. Many studies have reported that XR systems help reduce the symptoms of mental disorders. For instance, some authors [26,41,44] have strongly indicated that using XR technology in the psychotherapy process reduced anxiety and depression in their subjects. Similarly, Niharika et al [63] showed a significant decrease in subjects' anxiety scores when using VR eyeglasses during dental treatment.

XR intervention is a safe, noninvasive technique that does not require any previous education and training and has lasting effects. However, McLay et al [59] showed that statistically significant differences between XR-based treatment and conventional approaches may not be a constant thing when applying XR systems for mental disorder intervention. In comparison to standard CBT, some authors [60,73] have improved the psychotherapy of depressive disorder in young adults by developing effective VR-enhanced personal construct therapy. Arnfred et al [101], in the SoREAL study, investigated in vivo group CBT and compared its effects with those of VR exposure CBT on patients diagnosed with social anxiety disorder. Similarly, Shin et al [107] and Donker et al [110] investigated the efficacy of mobile-based VR CBT for panic disorder and phobia interventions. The app-based XR interventions were effective in managing disorder symptoms and restoring subjects' autonomic nervous system. This demonstrates the validity of using XR systems as self-guided and cost-effective therapeutic approaches. Taken together, these studies show that the recent development of XR technologies is gaining traction for mental disorder evaluation and treatment. Thus, some researchers have suggested that future XR interventions should consider providing multiuser experiences that can help increase social engagements for patients who are possibly confined due to disabilities. It can be concluded that virtual environments are as effective as exposure therapy for evaluating mental health. We found studies investigating whether gamified XR is also effective in reducing acrophobia, and the stimuli presented using AR, indeed, induced physiological alterations in the participants [43,44,80].

Effects of XR Design Factors on the Outcomes of Mental Disorder Interventions

Brás et al [78] showed that AR and VR offer high levels of immersion and are optimal solutions for counteracting the effects of in vivo exposure. Weerdmeester et al [74] showed that by engagement and cognitive biofeedback, gamified VR can reduce anxiety symptoms. Grieger et al [81] investigated whether XR-based interventions with multiple design factors can yield better results when used for mental disorders. In a randomized controlled trial, the authors found that personalized VR aids a general positive shift in thoughts and emotions, with increased relaxation and self-refection [81]. This shows that VR systems with multiple features, such as personalization, immersion and focus, interaction design and embodiment, and integration, can enhance treatment outcomes. Similarly, De Asis et al [82] developed a mobile VR-based system for promoting relaxation to reduce anxiety and alter stressful activities among class students. Studies conducted by El-Qirem et al [91] and Traister [79] have shown that XR technology can significantly lower students' anxiety and enhance them psychologically and physiologically with a safe and risk-free therapeutic experience. The related studies [56,57] focused on mental stress management in teenagers and adolescents. Brivio et al [39] compared the efficiencies of 360° panorama technology and a computer-simulated prototype in generating an XR sense of presence, emotions, and relaxation when treating mental disorders. In addition, Lundin et al [98] investigated whether filming virtual environments with a low-cost 360° film camera to produce VR CBT can offer a feasible and acceptable treatment for some kinds of phobia. These studies show that VR exposure therapy can produce long-lasting benefits for mental disorders, consistent with research on a variety of forms of short-term CBT for social anxiety disorder. The results showed that treatment satisfaction was high and that participants had significant improvement at 6-month follow-up, with large effect sizes [98]. Another study [87] showed that VR relaxation induces positive affective states and has short-term effects toward reducing psychiatric stress and anxiety disorder symptoms compared to standard relaxation exercises.

Limitations

XR-based systems have some unique advantages over traditional methods used for mental disorder management. Nevertheless, XR systems also have some limitations. Future developments should consider technological innovation and standardization of treatment options. The following limitations should be considered when interpreting the results of this review. The search strategy developed was limited to using PubMed, Google Scholar, and the ACM Digital Library databases for efficient and accurate search results. This may have excluded qualified papers from other databases. We also found that the number of weeks of evaluation in 40 studies and the number of sessions in 23 studies were not specified in the selected papers. Thus, it is difficult to assert the best number of weeks and sessions needed to validate the use of XR-based technology in mental disorder evaluation. This review identified various major methodological approaches and development tools used by studies. Another limitation of the study is the lack of scientific assessment of the quality of the publications that were included in the scoping review. Moreover, due to the large number of papers reviewed, there is a possibility of that we overlooked valid publications that might have met the inclusion criteria. Non-English papers were not included in this review either. Finally, considering the possibility of bias in the reported outcomes for many reasons, including due to self-reporting and publishing bias that tend to favor papers with positive outcomes, the findings of this scoping review should be applied with caution, especially regarding the effectiveness of XR-based intervention for mental disorders.

Conclusion

XR therapy has been widely used in the care of a variety of mental disorders. This scoping review investigated the adoption of XR for mental disorders, specifically anxiety and depression. The review covered 85 studies that used different types of VR, AR, and MR technologies for mental disorders, with a focus on anxiety and depression. We uncovered that the majority of reviewed papers reported a reduction in the symptoms of anxiety or depression with the use of XR. Moreover, the studies adopted unique designs that were set up to monitor the signs of mental disorders. The recorded signs can be used for formulating appropriate therapies. We also found that XR-based interventions have been shown to be effective approaches with a high level of user acceptability in 18 mental health conditions. Although a considerable number of studies (N=85) were included in this scoping review, some areas are still underinvestigated and, hence, not well represented in the reviewed studies. For instance, the adoption of nongamified strategies was found to have cut across 18 mental health conditions included in this review. However, studies investigating pain and anxiety, negative thoughts, autoimmune disorders, and acquired brain injury did not use any form of gamification strategies. This study was conducted to investigate the implementation and adoption levels of XR for mental health care delivery. Our study outputs indicate that many studies have focused on anxiety, either alone or in combination with other conditions. Meanwhile, a limited number of studies have solely focused on depression. In a previous study, Baghaei et al [124] also showed that supporting people with depression in XR settings is an interesting area to explore for mental health care. We recommend that future work should conduct controlled trials to investigate and compare the effectiveness of using XR-based intervention in mental health care and the benefits and costs of XR in mental disorder management.

Abstract

Background: Serious games (SGs) are nonpharmacological interventions that are widely applied among older adults. To date, no evidence has been published regarding the effect of digital SGs on cognitive ability, daily behavioral capacity, or depression in older adults with Alzheimer's disease (AD) and mild cognitive impairment (MCI).

Objective: This study aimed to assess the effect of SGs on older adults with AD and MCI by summarizing and pooling the results of previous studies.

Methods: This meta-analysis examined the effectiveness of digital SGs in improving cognitive ability, enhancing daily behavioral capacity, and alleviating depression in older adults with AD and MCI. We searched the following databases up to December 31, 2023, to identify relevant high-quality randomized controlled trials (RCTs): PubMed, Embase, Web of Science, Scopus, and Cochrane Library. Stata 15.1 and Review Manager 5.3 were used to screen the 14 studies, extract data, code the data, and perform meta-analysis. Mean differences and standardized mean differences (SMDs) with 95% CIs were used to calculate continuous variables. The Cochrane risk-of-bias assessment tool was used to evaluate the risk of bias. Eligibility criteria were developed in accordance with the Population, Intervention, Comparison, Outcomes, and Study Design framework: (1) population (older adults with AD and MCI), (2) intervention (digital SG intervention), (3) comparison (digital SG intervention vs routine health care), (4) outcomes (cognitive ability, daily behavioral capacity, and depression), and (5) study or research design (RCT). Sensitivity analysis was performed, and a funnel plot was constructed.

Results: From January 2017 to December 2023, we enrolled 714 individuals across 14 RCTs, with 374 (52.4%) in the severe game group using digital SGs and 340 (47.6%) in the control group using traditional methods. The results of our meta-analysis indicated that using digital SGs in older adults with AD and MCI is more effective than traditional training methods in several key areas. Specifically, digital SG therapy significantly increased cognitive ability, as found in the Mini-Mental State Examination (SMD 2.11, 95% CI 1.42-2.80; $P<.001$) and the Montreal Cognitive Assessment (SMD 2.75, 95% CI 1.98-3.51; $P<.001$), significantly increased daily behavioral capacity (SMD 0.53, 95% CI 0.06-0.99; $P=.03$), and significantly reduced depression (SMD –2.08, 95% CI –2.94 to –1.22; $P<.001$) in older adults with AD and MCI. No publication bias was detected based on the results of Begg and Egger tests.

Conclusions: Digital SGs offer a viable and effective nonpharmacological approach for older adults with AD and MCI, yielding better results compared to traditional formats. However, caution is warranted in interpreting these findings due to limited RCTs, small sample sizes, and low-quality meta-analyzed evidence.

Introduction

Alzheimer's disease (AD) and mild cognitive impairment (MCI) are among the most common diseases affecting older adults. As the worldwide population is aging, the incidence of AD and MCI is gradually increasing, leading to major challenges for older adults. AD and MCI are being increasingly researched worldwide because of their adverse effects on cognitive ability, daily behavioral capacity, and depression among older adults. Currently, more than 55 million people worldwide have dementia [1]. Dementia is a progressive degenerative disease of the central nervous system that metastasizes through different clinical stages [2] and is characterized by abnormal behavior, declining cognitive function, and declining daily living ability [3]. Dementia affects multiple aspects of cognitive function, including complex attention, memory and learning, perceptual-motor skills, social cognition, and language [4]. AD is the most common form of dementia and may account for 60%-70% (38.77 million) of the 55 million cases of dementia [5]. MCI is an intermediate stage between dementia and normal aging [6]; clinicians and researchers consider the stage of MCI to be a "window" for potentially delaying the progression into dementia [7]. Moreover, the number of MCI cases among individuals above the age of 60 years is 5.82 million [8]. In 2019, the worldwide economic cost of dementia amounted to US $1.3 trillion, of which approximately 50% (US $0.65 trillion) involved care provided by informal caregivers (eg, family members and close friends), who provided an average of 5 hours of care and supervision per day [9]. China has the largest number of patients with dementia worldwide, which leads to a huge burden on the health care and public system [10]. Approximately 13.75 million (25%) of 55 million people with dementia are Chinese [11], and thus, this country ranks first in the world. The results of a recent national cross-sectional study showed that there are 16.07 million people aged 60 years and over in China who have dementia; 9.83 million of these individuals have AD [11]. Presently, there is no known cure for dementia; health care and medication can only slow the disease progression [12].

When older people get MCI and AD, they experience a range of painful experiences related to this particular stage of life, such as depression [7,13], decreased cognitive ability [7,14], and decreased daily living ability [15,16]. Sudden illness can cause patients to experience both physical and psychological pain [17]. A significant proportion of the population with MCI and AD reports higher levels of perceived [18]. Depression is characterized by threats that exceed an individual's coping abilities, thus resulting in a feeling of being overwhelmed [19]. A growing body of evidence suggests that several important dimensions of life are frequently sacrificed when individuals get MCI and AD, and cognitive ability, daily behavioral capacity and depression are often neglected. Therefore, digital serious games (SGs) for older adults with MCI and AD may be crucial in the early intervention and prevention of these mental and physical disorders [20]. According to a previous report, even in worse cases, mental and physical disorders are risk factors for MCI and AD [21]. Patients with MCI and AD are completely dependent on caregivers, have markedly impaired memory function, are unable to take care of themselves in daily life, exhibit incontinence, and may even be completely unable to speak and have hemiplegia [22]. MCI and AD even cause an increase in the risk of mortality [23], which significantly damages people's health and imposes a growing burden on individuals and the entire society. Therefore, it is highly emergent to develop nondrug therapies and use them in the field of social work for older adults. This may slow the progression of cognitive disability in individuals with MCI and AD to combat personal and socioeconomic problems, to address the alarming increase in the incidences of MCI and dementia worldwide, and to overcome the lack of effective drug treatments for these diseases.

There are many therapeutic methods for treating MCI and AD in older adults. Game therapy has been recommended as a nonpharmacological treatment method due to its limited side effects. According to recent meta-analyses [24-26], game therapy could increase cognitive ability [26] and daily performance ability [27,28] and alleviate depression [29,30] in older adults with MCI and AD. Game therapy refers to an intervention method in which games are used as a therapeutic medium. This therapy originated from a child psychoanalysis program developed by the famous psychologist Sigmund Freud. He observed that there is a relationship between early childhood development and children's games. In the discussion of children's control of emotions through games, Freud presented the rationale for game therapy [31]. After nearly a century of clinical development, the therapeutic function of games has been proven in practice [32,33]. SGs may take many forms, depending on their treatment, such as (1) cognitive training games, which are mainly used to improve or maintain users' cognitive abilities (eg, memory, executive function, and memory) [34-37]; (2) sports games or video games, in which part of the game needs to include exercise [38,39]; (3) biofeedback games, which use electronic sensors connected to the participant's body to receive information about their physical status (eg, an electrocardiograph sensor), with the aim of adjusting some bodily functions (eg, heart rate) [39-46]; and (4) cognitive behavioral therapy (CBT)–based games that provide computerized computer-based training. Due to the popularity of smart devices, handheld computers, personal computers, video game consoles, tablets, and smartphones, there is a wide variety of SGs [47,48]. Digital SGs, as defined in this paper, are SGs played through digital media. Digitally designed games help promote mental health [49], emotions [50], well-being [51], social function [51], and cognitive flexibility [52] compared to traditional cognitive training and exercise [53].

With respect to the development of game therapy theory, many studies have shown that game therapy is applicable for older adults [54]. The introduction of virtual reality technology has recently provided a new way to implement environmental enrichment in the context of clinical practice, which improves the physical health of patients with MCI and AD [55], treats chronic disease [56], increases cognitive ability [57] and daily behavioral capacity [50,52], alleviates depression [58], and increases self-esteem [59] and cohesion [60] by combining virtual immersion with cognitive stimulation. In conclusion, SG therapy is regarded as a promising treatment strategy for older adults with dementia and MCI in terms of increasing cognitive ability, improving daily behavioral capacity, and alleviating mental health issues. Game therapy is therefore increasingly used in gerontology, with the goal of providing psychosocial stabilization and support.

There are a few research gaps. First, there are inconsistent clinical results regarding the effects of SG therapy on cognitive performance, daily performance, and depression. According to Saragih et al [21] and Ning et al [60], SGs have been shown to improve cognitive function. However, Huang et al [61] and Kleschnitzki et al [62] reported that no significant changes are found in cognitive function or global status after virtual reality intervention. Wang et al [63] discovered that SGs have a positive impact on executive function. However, Abd-Alrazaq et al [52] found that there is no difference between adaptive SGs and nonadaptive SGs in improving executive function, although daily behavioral capacity is particularly related to executive function, such as scheduling appointments, making monthly payments, managing the household economy, shopping, or taking the bus. This means the effect of SGs in improving daily behavioral capacity is yet to be explored. Bai et al [50] compared SGs with intervention-free practices and found that game-based interventions lead to clinically and statistically significant improvements in depression severity. Bojan et al [64] discovered that SGs can cause a significant increase in positive emotions and a decrease in negative emotions [11,65]. However, according to Fitzgerald et al [66], whether SGs can improve depression in some cases is worth exploring. Therefore, there are inconsistent clinical results regarding the effects of SG therapy on cognitive performance, daily performance, and depression. A more comprehensive review is needed to systematically evaluate the effects of SGs on the physical and mental health of older adults with AD and MCI. Second, the previous literature only focused on SGs for a type of disease for older adults. Manca et al [67] observed the positive impact of SGs with humanoid robots on older adults with MCI. Pacheco et al [68] found that exergames improve balance and mobility in older adults to keep performing balance exercises. Yu and Chan [69] discovered video game training can effectively improve the cognition of older adults. This study investigated the effects of SGs on the cognitive ability, daily behavioral capacity, and depression of older adults with MCI and AD simultaneously. Third, it is important to investigate not only the effects of SGs but also the variables that may influence their effectiveness, including the duration of treatment and the target population. In this research, we used weeks and continental plates (within and outside Europe) to divide the subgroup analysis, which was not available in previous studies. In view of this, we conducted a systematic review and meta-analysis to comprehensively evaluate the effect of digital SGs on cognitive ability, daily behavioral capacity, and depression of older adults (≥60 years old) with MCI and AD.

Methods

Data Sources and Search Strategy

This review was conducted in strict accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [70]; also see Multimedia Appendices 1 and 2 [71]. We registered the study in PROSPERO (Prospective Register of Systematic Reviews; CRD42023486090). We used the PICOS (Population, Intervention, Comparison, Outcomes, and Study Design) framework [72] to structure study inclusion and exclusion criteria (Table 1). Our population of interest had at least 1 indicator indicating cognitive ability, behavioral ability, or emotion-related ability, and their age was ≥60 years. We sought studies describing interventions with digital SGs implemented among older adults with cognitive impairment in an experimental group (severe game group [SGG]), including exergames or video games, cognitive training games, computerized CBT-based games, and biofeedback games. There were no restrictions regarding the time of intervention. For comparison, we had a control group (CG) that received a different intervention, such as routine health care, traditional Tai Chi, or music. Our outcomes of interest included cognitive ability, daily behavioral capacity, and depression in older adults with cognitive impairment. We excluded studies that presented reviews, non–randomized controlled trials (RCTs), and papers for which the full text was unavailable. All included studies were published in Chinese or English. Studies in which the results were interpreted from the perspective of older adults with cognitive impairment were deemed eligible.

Table 1. Inclusion and exclusion criteria.

Element	Inclusion criteria	Exclusion criteria
Population	• At least 1 indicator representing cognitive ability, behavioral ability, or emotion-related ability • Age≥60 years	N/A[a]
Intervention	• Digital SGs[b] (eg, exergames, video games, cognitive training games, computerized CBT[c]-based games, biofeedback games)	N/A
Comparison	• Different interventions (eg, routine health care, traditional Tai Chi, music)	N/A
Outcomes	• Cognitive ability • Daily behavioral capacity • Depression	N/A
Study design	• RCT[d]	• Reviews • Non-RCTs • Papers with full text unavailable
Language	• Chinese or English papers	• Not Chinese or English papers

[a]N/A: not applicable.
[b]SG: serious game.
[c]CBT: cognitive behavioral therapy.
[d]RCT: randomized controlled trial.

Search Strategy

The following databases were searched to identify the relevant literature: PubMed, Embase, Web of Science, Scopus, and Cochrane Library. The following search terms were used for the search: ("Cognitive Ability" OR "Daily Behavior Ability" OR "Mental Health" OR "Depression") AND ("Serious Games Based" OR "Serious Games" OR "Web-Based or Mobile") AND ("Old Adults in Cognitive Impairment" OR "Old Adults" OR "Older People") AND ("A pilot study" OR "Randomized Controlled Trial" OR "RCT"). Detailed search strategies for each database are given in Multimedia Appendix 3. The keywords were used to search for papers published from January 1, 2017, to December 31, 2023. The snowball method was adopted to search the reference lists of the included studies. Additionally, the reference lists of the included studies were manually searched to identify eligible papers. Unpublished academic literature was not considered eligible. The reference lists and relevant reviews were then screened to identify any pertinent studies. To identify additional relevant publications, we also retrieved gray literature [73].

Data Extraction

Four researchers (authors XZ, YT, YC, and ZZ) screened all the literature for inclusion. After removing duplicates using EndNote X9, all studies were independently screened based on titles and abstracts. Next, we carefully read the full texts of the remaining papers in accordance with the inclusion and exclusion criteria. Finally, data were extracted from the included studies. The co-first author (XZ) used the modified version of the data extraction table in the *Systematic Review Manual of Cochrane Interventions* to extract data. A modified version of the intervention description and replication was using following the template for intervention description and replication (TIDieR) list and guidelines [74] to extract data of the intervention, design, and delivery features, as defined in the introduction. First, data were extracted by the co-first author (XZ). Next, the second author (ZZ) checked the accuracy of the process. Finally, the co-first author (YC), through thematic analysis [75], extracted the following data from the list of 14 studies [34-47]:

- Study characteristics: name of author, publication year, country, publication type, and study design
- Subject characteristics: sample size, participant mean age, participant age, Mini-Mental State Examination (MMSE) score, participant health conditions, and population group
- Intervention details: setting, intervention type, delivery mode design (how), content (ie, procedures, materials, process, activities [what]), and delivery details (ie, intervention delivery format, intervention duration, session length, session frequency, intensity)
- Study quality: Jadad score
- Main outcomes: reported results, conclusion, measurement, and follow-up

Risk-of-Bias Assessment and Quality Assessment

Using the Cochrane Collaboration risk-of-bias tool [76], we independently assessed the risk of bias. Additionally, we assessed the quality of the 14 studies using the Jadad scale [77]. The risk-of-bias tool assesses 7 domains: (1) generation of a random sequence, (2) allocation concealment, (3) subject and experimenter blinding, (4) outcome assessor blinding, (5) resulting data integration, (6) selective reports, and (7) other bias risk. Each study was categorized as having a low, high, or unclear risk of bias. We also performed Begg and Egger tests to evaluate the degree of publication bias [78].

Statistical Analysis

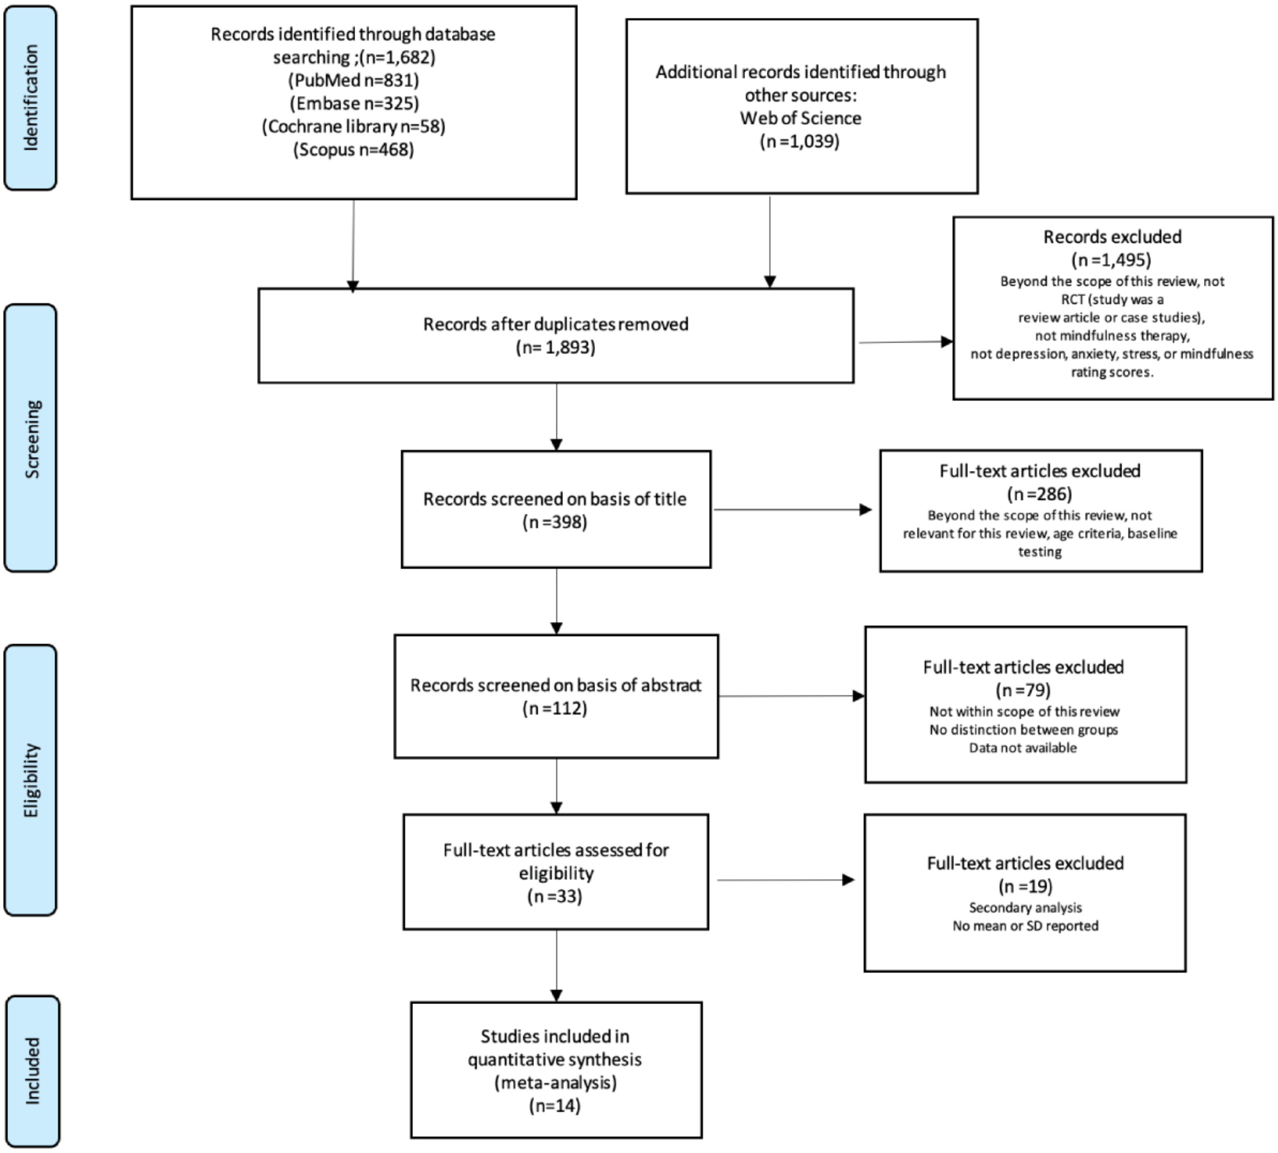
Stata 15.1 and Review Manager 5.3 were used to conduct data analysis. Forest plots were constructed to intuitively illustrate the results. In the included literature, the outcomes were measured as continuous variables, and the same indicator was assessed with different tools. These indicators were presented as standard mean differences (SMDs). α=.05 was considered statistically significant. Heterogeneity was assessed with I^2 statistics, which were classified as high (>75%), moderate (50%-75%), or low (<50%) [79]. In cases of high heterogeneity, sensitivity analysis was performed using the leave-1-out method to identify the sources of heterogeneity. In the analysis, numerous weeks were compared as subpoints to check the results. The Begg test [80] and Egger test [81] were used to assess publication bias. P<.05 indicated significant results. When a meta-analysis included at least 10 studies, publication bias was evaluated with a funnel plot [82,83]. In this study, 95% CI and the SMD were examined [84]. Overall, P<.05 indicated statistically significant effects. Subgroup analyses were performed based on the country of intervention (outside Europe or not) and the length of intervention (weeks).

Results

Study Selection

Figure 1 shows the study selection process. After searching 13 databases, 4260 relevant records were identified. For duplicate removal, we imported all the studies into EndNote X8 [85]. After removing 1893 (44.4%) duplicates and eliminating 2352 (55.2%) papers via a strict screening process, 14 (0.3%) RCTs [34-47] from before December 2023 involving 714 participants were finally included. Studies were excluded because they did not report SDs [26,86-88], were review papers [89,90], or were not within the scope of this meta-analysis [91-94]. All the included studies reported that digital SGs have a positive impact on cognitive ability, daily behavioral capacity, and depression. The primary outcomes of interest were an increase in cognitive ability scores (assessed with the MMSE and the MoCA), an increase in daily behavioral capacity indicators (assessed with the Barthel Index, the Katz Index, the Lawton and Brody Index, the Korean version of the Modified Barthel Index [K-MBI], and the Activities of Daily Living [ADL] scale), and a reduction in depression (assessed with the Goldberg Anxiety and Depression Scale [EADG], the 15-item Geriatric Depression Scale [EDG-15], and the Cornell Scale for Depression in Dementia [CSDD]).

Figure 1. Study selection flowchart based on PRISMA guidelines, 2020. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Study Characteristics

Table 2 and Multimedia Appendix 4 [34-47] show the overall characteristics of the included studies. All 14 studies were published before 2023. The sample sizes ranged from 17 to 112, and 714 older adults aged >60 years were enrolled in the included studies, including 340 (47.6%) subjects in the SGG and 374 (52.4%) subjects in the CG. All participants were older adults with cognitive impairment, but they had not been diagnosed with psychiatric disorders. All interventions were based on digital SGs, and their durations ranged from 4 weeks to 12 weeks. The interventions lasted from 45 minutes to 5 hours each week. Both group training and individual training methods were used [34-47]. All 14 studies [34-47] were subdivided into digital SG training methods (exergames or video games, cognitive training games, computerized CBT games, and biofeedback games).

Table 2. Characteristics and findings of the included studies (N=14)[a].

Study	Location	Sample size: SGG[b] and CG[c], n/N (%)	Age (years): SGG and CG, range (average)/mean (SD)	Disease	Time frame (weeks)	Reported results and conclusion
Yang et al [34]	Republic of Korea	SGG: 10/20 (50) CG: 10/20 (50)	SGG: 64-78 (71.1) CG: 61-78 (69.9)	Dementia	4	Result: Postintervention, the K-MMSE[d] score of the SGG was higher than that of the CG. Conclusion: Computer-based CBT[e] training might have beneficial effects on general cognitive function in the early stage of AD[f].
Kwan et al [35]	Hong Kong, China	SGG: 16/33 (48) CG: 17/33 (52)	SGG: (average): 70.5 CG: (average): 71	Dementia	12	Result: Postintervention, the MoCA[g] score of the SGG was higher than that of the CG. Conclusion: The mobile health (mHealth) intervention is feasible for implementation in older people with cognitive impairment and is effective at enhancing cognitive function.
Lim et al [36]	Republic of Korea	SGG: 12/24 (50) CG: 12/24 (50)	SGG: 69-81 (75.42) CG: 65-90 (73.33)	Dementia	4	Result: Postintervention, the K-MMSE, K-MoCA[h], and DQoL[i] scores of the SGG were higher than those of the CG. Conclusion: The research group showed significant improvement in cognitive function after training. Family SGs[j] are believed to help improve cognitive function.
Lee et al [37]	Republic of Korea	SGG: 10/20 (50) CG: 10/20 (50)	SGG: 65-83 (74.5) CG: 65-82 (74)	MCI, AD, dementia	3	Result: Postintervention, the K-MMSE and ADL[k] scores of the SGG were higher than those of the CG. Conclusion: Through this preliminary study, we verified that the newly developed computerized cognitive rehabilitation program is effective in improving cognitive function.
Yang [38]	Fujian, China	SGG: 44/88 (50) CG: 44/88 (50)	SGG: 62-83 (71.89) CG: 61-82 (71.63)	Dementia	12	Result: Postintervention, the MMSE[l] and ADL scores of the SGG were higher than those of the CG. Conclusion: Interactive games can improve the cognitive function and daily living ability of patients with senile dementia.
Van Santen et al [39]	Netherlands	SGG: 73/112 (65) CG: 39/112 (35)	SGG: 73-85 (79) CG: 72-86 (79)	Dementia	8	Result: Postintervention, the MMSE score of the SGG was higher than that of the CG. Conclusion: Sports games can improve the cognitive function of patients with senile dementia.
Zheng et al [40]	Zhejiang, China	SGG: 18/38 (47) CG: 20/38 (53)	SGG: 75-87 (81.74) CG: 78-89 (84.26)	Dementia	8	Result: Postintervention, compared to the CG, the MMSE score of the SGG was significantly higher and the CSDD[m] score was significantly lower. Conclusion: Somatic interactive game interventions can improve memory and language function and reduce depression in older patients with dementia, but the impact on cognitive function and ADL needs to be explored.
Wu et al [41]	Shandong, China	SGG: 47/94 (50) CG: 47/94 (50)	SGG: 61-80 (71.74) CG: 60-80 (72.65)	Dementia	12	Result: Postintervention, the MoCA score of the SGG was higher than that of the CG. Conclusion: Sensory stimulation combined with sensory interaction games can improve cognitive function.
Savulich et al [42]	United Kingdom	SGG: 21/42 (50) CG: 21/42 (50)	SGG: 67-82 (75.2) CG: 68-85 (76.9)	Dementia	4	Result: Postintervention, the MMSE score of the SGG was higher than that of the CG. Conclusion: Gamification maximizes engagement with cognitive training by increasing motivation and could complement pharmacological treatments for amnestic MCI[n] and mild AD.

Study	Location	Sample size: SGG[b] and CG[c], n/N (%)	Age (years): SGG and CG, range (average)/mean (SD)	Disease	Time frame (weeks)	Reported results and conclusion
Swinnen et al [43]	Belgium	SGG: 23/45 (51) CG: 22/45 (49)	SGG: 79-90 (84.7) CG: 78-91 (85.3)	Dementia	8	Result: Postintervention, compared to the CG, the MMSE, MoCA, and DQoL scores of the SG were higher and the CSDD score was significantly lower. Conclusion: Individually adapted exergame training improves lower extremity functioning, cognitive function, and depression in long-term-care facilities.
Liu et al [44]	Taipei, China	SGG: 16/33 (48) CG: 17/33 (52)	SGG: 68-80 (74.6) CG: 66-79 (73.4)	Dementia	12	Result: Postintervention, the MoCA score of the SGG was higher than that of the CG. Conclusion: Exergaming-based Tai Chi is comparable to traditional Tai Chi for enhancement of cognitive function.
Thapa et al [45]	Republic of Korea	SGG: 34/68 (50) CG: 34/68 (50)	SGG: 67-78 (72.6) CG: 67-78 (72.7)	MCI, dementia	8	Result: Postintervention, the MMSE score of the SGG was higher than that of the CG. Conclusion: Encouraging patients to perform virtual reality– and game-based training may be beneficial to prevent cognitive decline.
Oliveira et al [46]	Portugal	SGG: 10/17 (59) CG: 7/17 (41)	SGG: 77-88 (82.6) CG: 77-90 (84.14)	Dementia	5	Result: Postintervention, the MMSE and ADL scores of the SGG were higher than those of the CG. Conclusion: This approach is effective for neurocognitive stimulation in older adults with dementia, contributing to maintaining cognitive function in AD.
Jahouh et al [47]	Spain	SGG: 40/80 (50) CG: 40/80 (50)	SGG: 85.05 (8.63) CG: 83.25 (8.78)	MCI	8	Result: Postintervention, the MMSE and ADL scores of the SGG were significantly higher and the EGD-15[o] and EADG[p] scores were significantly lower than those of the CG. Conclusion: The Wii video console has a positive influence on older people by increasing cognitive ability, enhancing the level of ADL, and improving the psychological status.

Risk of Bias and Quality Assessment

Figures 2 and 3 show the results of the risk-of-bias assessment. All 14 papers [34-47] described the randomization methods in detail. The blinding method was detailed in 7 (50%) studies: 4 (57%) of these studies were double-blind trials [40,44,45,47], while 3 (43%) were single-blind trials [36,37,46]. The average Jadad score across all included studies was 4.7, indicating fair-to-mild quality.

Figure 2. Risk-of-bias graph.

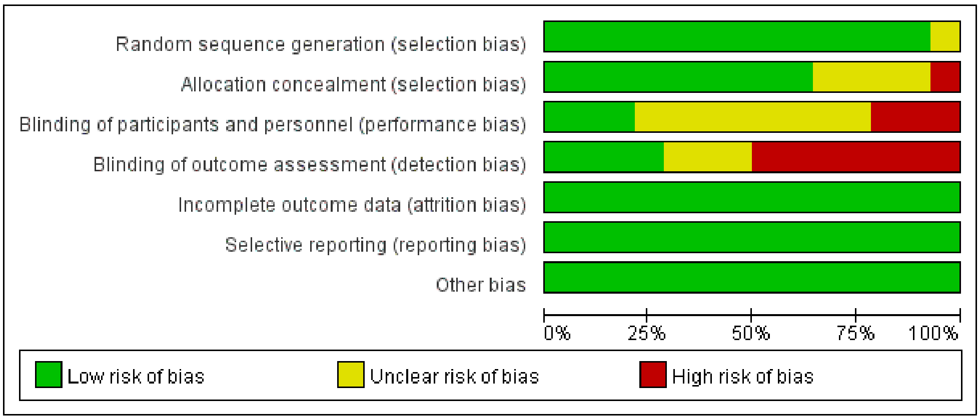

Figure 3. Risk-of-bias summary of the 14 studies included.

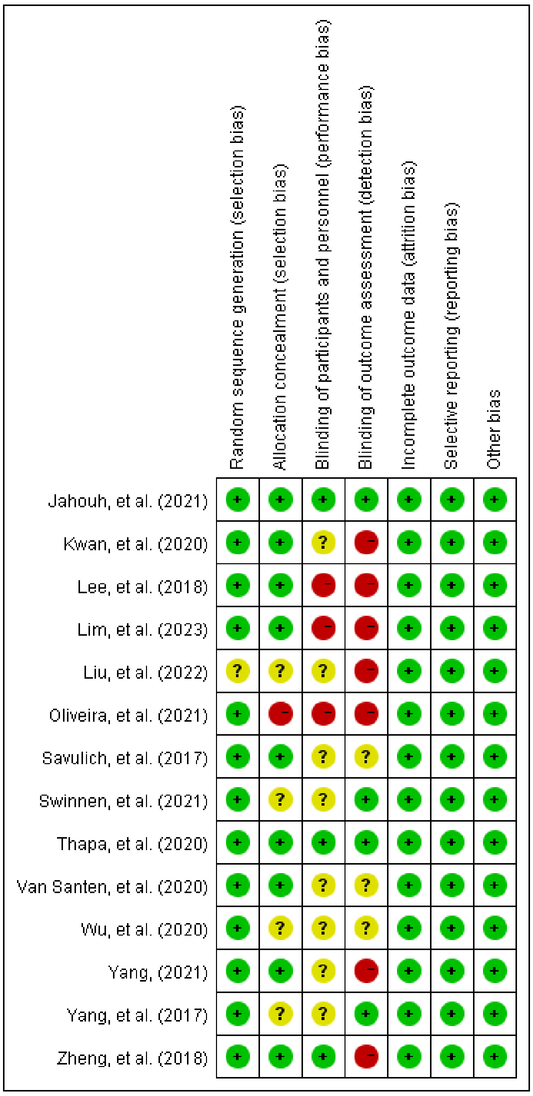

Meta-Analyses

Cognitive Ability Indicators

Of the 14 studies, 10 (71%) [34,36-40,42,45-47] involving 409 (57.3%) older adults (n=272, 66.5%, in the SGG and n=237, 33.5%, in the CG) assessed the effects of SGs on older adults' cognitive ability based on MMSE scores. Because different evaluation tools were used, the SMD was considered the pooled effect size measure. The pooled results revealed a low degree of heterogeneity among the studies (P=.23, I^2=23%), necessitating the use of a random effects model for the meta-analysis. Figure 4 demonstrates that cognitive ability scores in digital SGs significantly increased between the 2 groups under investigation (SMD 2.11, 95% CI 1.42-2.80; P<.001). Of the 14 studies, 5 (36%) [35,36,41,43,44] involving 229 (32.1%) older adults (n=114, 49.8%, in the SGG and n=115, 50.2%, in the CG) assessed the effects of SGs on older adults' cognitive ability based on MoCA scores. Because different evaluation tools were used, the SMD was considered the pooled effect size measure. The pooled results revealed a low degree of heterogeneity among the studies (P=.33, I^2=13%), necessitating the use of a random effects model for the meta-analysis. Figure 5 demonstrates that cognitive ability scores in digital SGs significantly increased between the 2 groups under investigation (SMD 2.75, 95% CI 1.98-3.51; P<.001).

Figure 4. Forest plot for MMSE. MMSE: Mini-Mental State Examination.

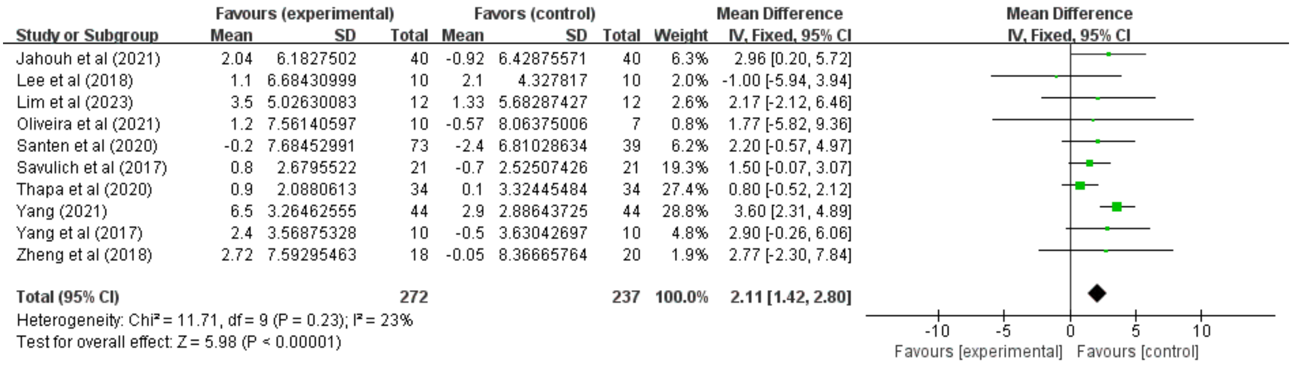

Figure 5. Forest plot for MoCA. MoCA: Montreal Cognitive Assessment.

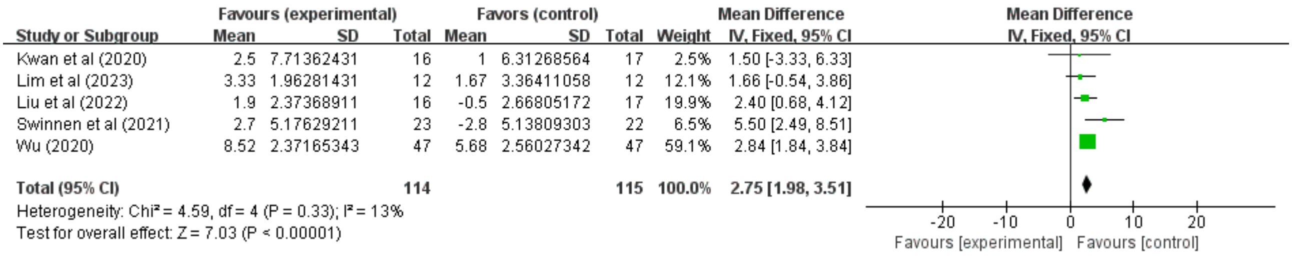
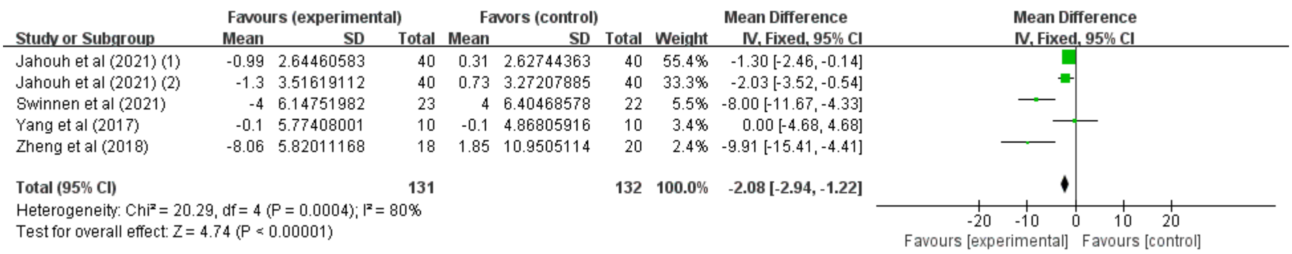


Daily Behavioral Capacity Indicators

Of the 14 studies, 6 (43%) [37,38,40,43,46,47] involving 448 (62.7%) older adults (n=225, 50.2%, in the SGG and n=223, 49.8%, in the CG) assessed the effects of SGs on older adults' daily behavioral capacity based on the Barthel Index, the Katz Index, the Lawton and Brody Index, the K-MBI, and the ADL scale. Because different evaluation tools were used, the SMD was considered the pooled effect size measure. The pooled results revealed significant heterogeneity among the studies (P=.03, I^2=91%), necessitating the use of a random effects model for the meta-analysis. Figure 6 demonstrates that daily behavioral capacity scores in digital SGs significantly increased between the 2 groups under investigation (SMD 0.53, 95% CI 0.06-0.99; P=.03).

Figure 6. Forest plot for daily behavioral capacity indicators.

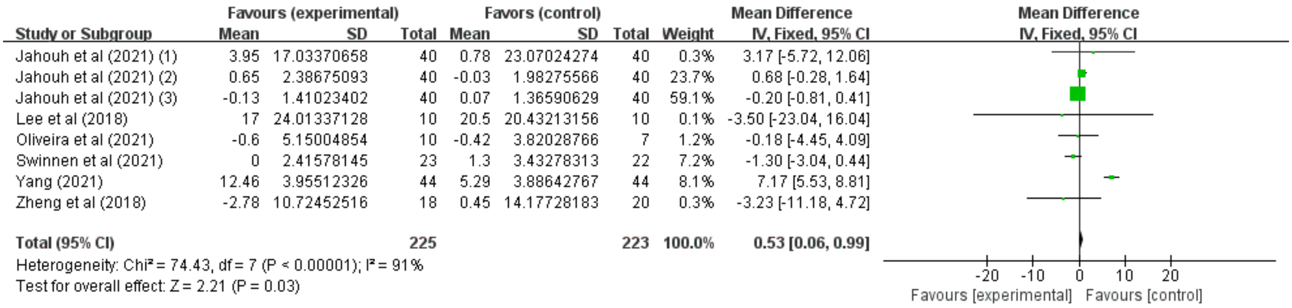


Depression Indicators

Of the 14 studies, 4 (29%) [34,40,43,47] involving 292 (40.9%) older adults (n=145, 49.7%, in the SGG and n=147, 50.3%, in the CG) assessed the effects of SGs on older adults' depression based on the EADG, the EDG-15, the Geriatric Depression Scale (GDS), and the CSDD. Because different evaluation tools were used, the SMD was considered the pooled effect size measure. The pooled results revealed a low degree of heterogeneity among the studies (P<.001, I^2=80%), necessitating the use of a random effects model for the meta-analysis. Figure 7 demonstrates that cognitive ability scores in digital SGs significantly increased between the 2 groups under investigation (SMD –2.08, 95% CI –2.94 to 1.22; P<.001).

In conclusion, the included studies reported scores on the MMSE, MoCA, the Barthel Index, the Katz Index, the Lawton and Brody Index, the K-MBI, the ADL scale, the EADG, the EDG-15, and the CSDD. A total of 3 outcomes were evaluated: cognitive ability, daily behavioral capacity, and depression. The SGG had significantly greater total MMSE scores than the CG (SMD 2.11, 95% CI 1.42-2.80; P=.23, I^2=23%), as shown in Figure 4. The SGG had significantly greater total MoCA scores than the CG (SMD 2.75, 95% CI 1.98-3.51; P=.33, I^2=13%), as shown in Figure 5. In addition, a reduction in daily behavioral capacity indicators was observed based on the Barthel Index, the Katz Index, the Lawton and Brody Index, the K-MBI, and the ADL scale. The SG led to increased daily behavioral capacity scores in the SGG (SMD 0.53, 95% CI 0.06-0.99; P=.03, I^2=91%), as shown in Figure 6, compared to the CG. The SGG also showed a decrease in depression based on the EADG, the EDG-15, and the CSDD (SMD –2.08, 95% CI –2.94 to –1.25; P<.001, I^2=80%), as shown in Figure 7.

Figure 7. Forest plot for depression indicators.



Subgroup Analyses

Subgroup analyses of daily behavioral capacity and depression scores were performed based on the country of intervention (outside or within Europe) and the duration of intervention (weeks). For daily behavioral capacity, significant differences were found in the SMD between the 2 subgroups: within Europe (P=.85) [43,46,47] and outside Europe (P<.001) [37,38,40]. SGs had a significant effect on the outcome in the outside-Europe group (SMD 6.68, 95% CI 5.08-8.28; P<.001), as shown in Figure 8. For depression, significant differences were found in the SMD between the 2 subgroups: within Europe (P<.001) [43,47] and outside Europe (P=.02) [34,40]. SGs had a significant effect on the outcome in the within-Europe group (SMD –2.08, 95% CI –2.94 to –1.22; P<.001), as shown in Figure 9. Of the 6 (43%) studies, 4 (67%) [38,40,46,47] reported a pooled effect of an intervention duration of ≥8 weeks (SMD 0.67, 95% CI 0.19-1.16; P=.007). For the remaining 2 (33%) studies [37,43], the pooled effect within the intervention period was as follows: SMD −1.32, 95% CI −3.05 to −0.42; P=.14. The effects of SGs on daily behavioral capacity during the 2 periods of intervention were significantly different from those in the CG (P<.001), as shown in Figure 10. For depression, no significant differences were found in the SMD between the 2 groups after >8 weeks (P=.005) [40,47] or <8 weeks (P=.008) [34,43], as shown in Figure 11. Among the 4 (29%) studies on depression indicators [34,40,43,47], 2 (50%) [40,47] had a combined effect in an intervention duration of ≥8 weeks (SMD −2.57, 95% CI −4.00 to −1.13; P=.005). For 2 (50%) studies [34,43] in which the intervention duration was <8 weeks, the combined effect within the intervention period was as follows: SMD −4.95, 95% CI −7.84 to −2.07; P=.008. An intervention period of 8 weeks or more had a significant effect on reducing cognitive impairment in older adults (Figure 11). Compared to with the CG, the effects of SGs on depression during the 2 periods of intervention were significantly different, and a significant difference between the 2 groups was found (P<.001), as shown in Figure 11.

Sensitivity Analysis

In the sensitivity analysis (Table 3), we excluded the study by Yang et al [38] and observed a significant change in heterogeneity from 91% to 0%. We hypothesized that the outcome of daily behavioral capacity indicators may have been the possible source of heterogeneity in this study. Additional possible reasons included the inclusion of patients, specific treatment modalities, and inconsistencies in clinical indicators between domestic and foreign countries. The patients included and specific treatment modalities, as well as the clinical indicators applied, in this study were as follows: Yang et al [38], Fujian (China), age 61-83 years; older adults with cognitive impairment, participated in somatosensory interactive games, and completed the MMSE and the ADL scale. All these different factors were possible sources of heterogeneity.

Table 3. Sensitivity analysis for daily behavioral capacity indicators after excluding a few studies.

Study excluded	Tool used	Heterogeneity analyses		
		χ^2 (*df*)	P value	I^2 (%)
Jahouh et al [47]	Barthel Index	74.09 (6)	<.001	92
Jahouh et al [47]	Katz Index	61.17 (6)	<.001	90
Jahouh et al [47]	Lawton and Brody Index	74.02 (6)	<.001	92
Lee et al [37]	K-MBI[a]	74.01 (6)	<.001	92

[b]IADL: Instrumental Activities of Daily Living.

[c]ADL: activities of daily living.

Publication Bias

We found that the funnel plots for the MMSE (Figure 12a), MoCA (Figure 12b), daily behavioral capacity indicators (Figure 12c), and depression indicators (Figure 12d) were all symmetrical, indicating the absence of publication bias. P>.05 indicated the absence of obvious publication bias. The Begg test (P=.03) and Egger regression (P=.026) also indicated a lack of publication bias.

Discussion

Principal Findings

This study systematically evaluated the efficacy of training older adults with cognitive impairment using digital SGs, drawing upon data from 14 studies with a total of 714 participants. Our findings revealed that digital SGs significantly alleviate depression and yield large improvements in cognitive ability and daily behavioral capacity. This suggests that SGs offer a highly effective alternative for older adults with cognitive impairment. Due to statistical heterogeneity, these results should be interpreted with caution. In this study, sensitivity analysis was used to explore the major sources of statistical heterogeneity to determine the impact of a single study on overall risk. The type of intervention (various digital SGs), sample size (range 17-112), intervention duration (range 4-12 weeks), weekly intervention time (range 45-300 minutes/week), type of CG (traditional Taijiquan group, routine health care group, music group), cultural background, measurement tools, or other confounding factors may have caused heterogeneity. To the best of our knowledge, this is the first meta-analysis and systematic review evaluating the effectiveness of the 3 outcome indicators of serious gameplay in older adults with cognitive impairment. In this study, SGs were found to significantly increase cognitive ability and daily behavioral capacity and decrease depression.

Previous studies have explored the effects of digital SGs on cognitive ability [57], daily behavioral capacity [95], and depressive emotion problems [96] in patients with MCI or AD. However, previous studies have reported inconsistent findings regarding the effects of digital SG therapy on cognitive function [21,60-62], daily behavioral capacity [52,63], and depression [21,50,64-66] in older adults with MCI or AD. This systematic review included the recent literature (2017-2023) and examined 3 indicators of the effects of SGs on cognitive ability, daily behavioral capacity, and depression among older adults with MCI or AD. Consistent with previous findings, our results indicated positive effects of SGs on MMSE [97] and CSDD [50,98] scores and negative effects on depression on EDG-15, EADG, and GDS scores. In addition, there was a significant increase in cognitive ability (measured with MoCA) and daily behavioral capacity (measured with the ADL scale, the K-MBI, the Instrumental Activities of Daily Living (IADL) scale, the Katz Index, the Barthel Index, and the Lawton and Brody Index). This systematic review is the first to simultaneously test the effects of SGs on the 3 indicators of cognitive ability, daily behavioral capacity, and depression. This systematic review also divided the subgroup analysis of weeks and continental plates, which was not available in previous systematic reviews.

SGs are defined as games that are not for entertainment purposes and are mainly used for prevention, education, diagnosis, screening, and rehabilitation [99,100]. The word first appeared in 1968 when Abt [101] named his new book on SGs. According to Clark's [101] proposed treatment, games can exist in a variety of forms, including (1) exergames or video games that require physical exercise as part of playing the games [38,39]; (2) cognitive training games, which aim to maintain or improve users' cognitive abilities (eg, executive function, memory, learning) [34-37]; (3) computerized CBT games, which are video games that provide CBT to the users; and (4) biofeedback games, which are video games that use electrical sensors attached to the player to receive information about the player's body state (eg, electrocardiogram sensors) and seek to influence some of the player's body functions (eg, heart rate). Special care units (SCUs), also known as dementia care units, began to appear in the United States in the 1980s for older adults with dementia [102]. With an increase in the number of older adults with dementia and the diversification of the demand for dementia care in the market, these SCUs provide not only services to older adults in institutions but also family counseling, care support, and community therapy services to older adults with MCI [103]. At the policy level, the United States also launched the National Plan to Address Alzheimer's Disease in 2012, with the goal of preventing and effectively treating AD by 2025 [104]. The latest SG therapy has also had a positive impact on easing the stress of dementia among older adults in US society [66]. However, the attention to older patients with MCI and AD in the West is much earlier than in China. Model-based projection data put China's older adults with dementia at 6.73-15.7 million in 2025; the number of older adults with dementia will increase to 10.018-23.3754 million in 2035 [105]. China's Circular on the Promotion of Dementia Prevention and Treatment Action (2023-2025) [106] formally focuses on groups such as older adults with MCI and AD at the national policy level. Ren et al [11] found that the 2015 annual treatment cost of patients with AD in China was US $167.74 billion, with ever-rising treatment costs expected to reach US $1.8 trillion by 2050. Older care facilities, social work stations, and counseling services in China may use SGs to carry out nonpharmacological treatments for patients with MCI and AD. This will provide both physical and psychological health improvements to older adults and at the same time reduce the financial burden on China. In traditional Chinese society, positive family and social relationships contribute to physical and mental health [107]. Due to the "Xiao Dao" culture, this also constitutes a unique social security system for older adults [108,109]. However, rapid industrialization and urbanization have changed these traditional arrangements [110]. Today, older adults are less likely to live with and interact with younger generations, which has resulted in older adults being isolated [111]. This has a direct impact on access to social care and financial security and even affects the physical and mental health of older adults [112]. SGs can provide opportunities for older adults to interact with others [113] and reduce the negative emotional impact on them [114]. In addition, the sports elements included in SGs [115] can exercise older adults' cognitive ability [67] and daily behavioral capacity [116] and may even promote intergenerational relationships [117]. Our findings also show that SGs can have a positive impact on cognitive ability and daily behavioral capacity and decrease depression in older adults. With this in mind, we suggest that nursing home caregivers, social workers, and psychologists consider using SGs in their work and collaborate with SG professionals to bring benefits to older adults with MCI or AD. This will slow down the cognitive loss in older adults with MCI or AD to a certain extent.

Strengths and Limitations

Compared with previous studies [90,118,119], this review is the only one to specifically evaluate the effects of SGs on older adults and related types of games. Because the study was conducted in strict accordance with PRISMA guidelines, it was a high-quality, transparent review. Only RCTs were included; this is the most rigorous method of studying causal relationships [120,121]. Therefore, the conclusions of this review are more credible. In this review, there was minimal publication bias. We searched 12 worldwide databases and included research from the United Kingdom, China, Belgium, the Netherlands, Portugal, Spain, and Korea. We also performed forward and backward checks of reference lists, and an all-around search strategy was applied. We searched a database of gray literature without restricting the search to a specific comparator, population, setting, or country, which made the samples more representative. Since all the processes (ie, data extraction, research selection, evidence quality assessment, and bias risk assessment) were independently conducted by 4 reviewers, there was no risk of bias in this review. In addition, because we used the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) method to evaluate the quality of evidence, this review will enable readers to draw more accurate conclusions. Where possible, our statistics integrate data, which will increase not only the power of the research but also estimates of the effects of digital SG therapy on cognitive ability, daily behavioral capacity, and depression. Moreover, due to the large sample size, we performed a subgroup analysis and a sensitivity analysis. In addition, this review used pre- and postintervention outcome data from each group to evaluate the effectiveness of each meta-analysis. All previous studies have reported the SD and average overall cognitive changes pre- and postintervention in each group. In addition, in these studies, there were significant differences in overall cognition between groups at baseline.

The limitations of this study should also be considered. First, due to the design of the systematic review, a causal relationship with a clear structure could not be inferred. Second, the outcome indicators of anxiety (EADG scores) and quality of life (Dementia Quality of Life (DQoL)) were also related to the mental health of older adults with cognitive impairment. However, with only 1 study reporting these findings, a comparison could not be made, so we did not include these indicators. Third, because of the limitations of the designs of the included studies, the randomization and blinding methods used were seldom described in detail. Only 11 studies described the randomization method. In contrast, randomization was only mentioned in other studies, but no explanation of the method used was provided. Blinding was only implemented in 7 studies. Fourth, since many potentially eligible studies were pilot RCTs or quasiexperiments published before 2017 or in languages other than English, we excluded them. As a result, some related research may have been missed. The reason for excluding these studies is that the internal validity of pilot RCTs and quasiexperiments is lower than that of RCTs [122,123]. In addition, we were also unable to translate all the non-English research literature. In our previous review, we found some studies published before 2017. However, serious progress has been made in the field of gaming in the past 7 years, so we did not include RCTs published before 2017. Fifth, this review focused on the short-term effects of SGs. This meta-analysis of pre- and postintervention data did not include follow-up data. We found that follow-up data were reported in only 4 studies, and there was no consistency between the follow-up periods. Therefore, it was impossible to evaluate the long-term effects of SGs on the cognitive ability, mental health, and daily behavioral capacity of older adults. The quality of the evidence in our meta-analysis was average, which may have affected the internal validity of the findings. Sixth, in this review, interest intervention was limited to SGs used as therapeutic interventions on digital platforms, so it would not have been possible to comment on and check the effectiveness of SGs and nondigital SGs used for other purposes, such as monitoring, screening, or diagnosis.

Research and Practical Implications

Since the review concentrated on the effectiveness of SGs in improving cognitive ability, daily behavioral capacity, and depression among older adults with cognitive impairment, researchers should evaluate the effectiveness of SGs by performing further reviews of their positive effects on cognitive abilities (eg, processing speed, executive function, learning, memory, speed), daily behavioral capacity (eg, executive function, capacity for reaction, upper limb activity), and mental health (eg, anxiety, stress, sleep quality, quality of life) among people in different age groups. We included some studies from middle-income countries, so the generalizability of the findings of this review may be limited to these countries. As the cultural, social, and economic conditions of middle-income countries are different, additional relevant research should be carried out. To date, only a few studies have assessed the effectiveness of SGs in improving cognitive ability. Therefore, additional research is needed to help draw clearer conclusions about the effectiveness of SGs. Due to the lack of follow-up data, the long-term effects of SGs were not evaluated in this review. To assess the long-term cognitive effects of SGs in a worldwide context, researchers should follow up with participants. A few studies did not report the SD or average global cognitive changes in each group before and after the intervention. In the future, relevant studies need to report this information to evaluate the effect more accurately. Because most of the existing studies have problems reporting results and choosing the randomization process, 8 studies had a low risk of overall bias. Therefore, when developing and reporting on RCTs, researchers should use recommended tools (eg, RoB-2 [124]) and follow recommended guidelines to avoid the aforementioned biases. Many studies have examined the worldwide impact of digital SGs on the cognition of healthy older adults [57], but this review revealed that only 14 studies have investigated the effects of digital SGs on older adults with cognitive impairment. We hope that researchers can perform additional research in this area to fill this gap.

According to the results of this review, SGs, especially digital SGs, exhibit greater effectiveness than a lack of interventions. These findings have meaningful implications for clinical practice since the use of SGs can improve cognitive ability and daily behavioral capacity and decrease depression in older adults with cognitive impairment. However, these findings should be interpreted with caution because the quality of the evidence is low in most meta-analyses. Moreover, most of the studies included in this review had some problems in terms of overall bias. Except for 7 studies [34,39,41-43,45,47], in all the other included studies, heterogeneity was high and the total effect was not accurate enough. Therefore, before more strong evidence is obtained, psychiatrists and psychologists should consider SGs as a complement to existing interventions rather than a direct substitute. In addition, the number of older persons worldwide will grow exponentially in the next few years, so we can try to use SGs to lighten the burden on the health care system. We can use SGs to improve the physical, psychological, social, and motor functions of older persons with cognitive impairment, thereby improving their quality of life [54,125]. Currently, many old people live alone and have limited social interactions, which can often lead to increased morbidity and mortality [126]. Older adults can play SGs in a relatively cozy environment (ie, at home), thus promoting their connections with friends and family [51]. In all the studies, the platforms for SGs were mobile devices (tablets and smartphones). Mobile devices are more popular than game consoles, cheaper than computers, and easier to access; thus, they are particularly popular. As of 2021, there were more than 7.1 billion mobile device users and 15 billion mobile devices worldwide [127]. Game and app developers can work together to develop SGs aimed at improving the mental health, daily behavior capacity, and cognitive ability of older people. These SGs can be operated and played using mobile devices. A survey of a small number of studies conducted in middle-income countries revealed that these countries seem to prefer SGs more than high-income countries do [128]. Middle-income countries lack many psychological professionals (currently 1 for every 10 million people). Therefore, more SGs should be developed in middle-income countries to improve the cognitive ability, mental health, and daily behavioral capacity of older persons in those countries.

Conclusion

Overall, SGs, particularly digital SGs, may be associated with increased cognitive function and daily behavioral capacity, as well as decreased depression, among older adults with cognitive impairment. However, we are still unable to draw definitive conclusions on the safety and effectiveness of SGs in improving the cognition, behavioral capacity, and mental health of older people with cognitive impairment. This is due to the poor quality of existing meta-analysis evidence, which is mainly caused by concerns about the bias of most studies, the accuracy of the total effect, and the high degree of evidence heterogeneity. Therefore, until more reliable evidence is obtained, psychiatrists, psychologists, patients, and social workers should all regard SGs as a complement to existing interventions rather than a direct substitute. Before SGs are used, their effectiveness and safety should be further reviewed and evaluated, mainly in terms of improving daily behavioral capacity (eg, reaction ability, executive function, upper limb activity) of people with or without cognitive impairment in different age groups, cognitive ability (eg, processing speed, executive function, learning, memory), and mental health aspects (eg, stress, anxiety, sleep quality, quality of life). Further research is needed to assess the safety of SGs, the effects of sports games, and their long-term effects. In the future, further research on methods for increasing the motivation of participants, reducing the rate of missing data, and maintaining the effects of SGs is needed. Second, due to study limitations, it was impossible to perform subgroup analyses for intervention types. Consequently, in-depth and stratified discussions and comparisons of different intervention types were performed. In the coming years, it will be necessary for researchers to perform higher-quality studies with larger samples to verify the effectiveness of SG for older adults with cognitive impairment.

Acknowledgments

We confirm the submission of this manuscript, the key message of the manuscript, and the uniqueness of the study. We express our gratitude to the reviewers for their valuable remarks. We also state that the paper authorship, research, and publication have received financial support from the National Social Science Foundation in China (19BSH161) and the Shenzhen University-Lingnan University Joint Research Programme (2023004).

Data Availability

In this study, the original contributions have been included in the supplementary materials, and further inquiries can be made directly from the corresponding author. No artificial intelligence was used in any portion of the manuscript writing.

All the claims made by this paper represent only those of the authors and do not necessarily represent the claims of the affiliated organizations or reviewers, editors, and publishers. The publisher does not guarantee or endorse any product that may be evaluated by this paper or any claim that may be made by its manufacturer.

Authors' Contributions

XZ and YT managed conceptualization, data curation, formal analysis, funding acquisition, investigation, methodology, project administration, resources, software, supervision, validation, visualization, writing—original draft, and writing—review and editing. YC was responsible for conceptualization, data curation, formal analysis, funding acquisition, investigation, methodology, project administration, resources, software, validation, visualization, writing—original draft, and writing—review. ZZ was responsible for data curation, formal analysis, methodology, resources, and writing—original draft.

Abstract

Background: Immersive virtual reality (VR) is a promising therapy to improve the experience of patients with critical illness and may help avoid postdischarge functional impairments. However, the determinants of interest and usability may vary locally and reports of uptake in the literature are variable.

Objective: The aim of this mixed methods feasibility study was to assess the acceptability and potential utility of immersive VR in critically ill patients at a single institution.

Methods: Adults without delirium who were admitted to 1 of 2 intensive care units were offered the opportunity to participate in 5-15 minutes of immersive VR delivered by a VR headset. Patient vital signs, heart rate variability, mood, and pain were assessed before and after the VR experience. Pre-post comparisons were performed using paired 2-sided *t* tests. A semistructured interview was administered after the VR experience. Patient descriptions of the experience, issues, and potential uses were summarized with thematic analysis.

Results: Of the 35 patients offered the chance to participate, 20 (57%) agreed to partake in the immersive VR experience, with no difference in participation rate by age. Improvements were observed in overall mood (mean difference 1.8 points, 95% CI 0.6-3.0; *P*=.002), anxiety (difference of 1.7 points, 95% CI 0.8-2.7; *P*=.001), and pain (difference of 1.3 points, 95% CI 0.5-2.1; *P*=.003) assessed on 1-10 scales. The heart rate changed by a mean of –1.1 (95% CI –0.3 to –1.9; *P*=.008) beats per minute (bpm) from a baseline of 86.1 (SD 11.8) bpm and heart rate variability, assessed by the stress index (SI), changed by a mean of –5.0 (95% CI –1.5 to –8.5; *P*=.004) seconds^{-2} from a baseline SI of 40.0 (SD 23) seconds^{-2}. Patients commented on the potential for the therapy to address pain, lessen anxiety, and facilitate calmness. Technical challenges were minimal and there were no adverse effects observed.

Conclusions: Patient acceptance of immersive VR was high in a mostly medical intensive care population with little prior VR experience. Patients commented on the potential of immersive VR to ameliorate cognitive and emotional symptoms. Investigators can consider integrating minimally modified commercial VR headsets into the existing intensive care unit workflow to further assess VR's efficacy for a variety of endpoints.

Introduction

Patients with critical illness experience many noxious sensations, stress, and restricted mobility while being treated in intensive care units (ICUs). There is a burgeoning evidence base demonstrating a loss in mental, emotional, and physical functioning after critical illness. Approaches to improve the experience of critical illness and functional outcomes after hospitalization are needed.

Immersive virtual reality (VR) has been proposed as a promising tool to address these issues [1,2]. Immersive VR often involves the use of a headset to project the viewer into an interactive artificial environment that elicits the feeling of embodiment in the artificial environment [3]. Preliminary work assessing the efficacy of immersive VR for physical and cognitive mobilization [4-8], sleep [9], distraction from pain [10,11], and mood [12,13] has been performed, with many further trials ongoing.

A major challenge to applying the results from prior studies of VR is that there are numerous permutations of how, when, and for whom immersive VR might be used. For example, the equipment [14], particular VR experience [14,15], and clinical purpose [3] may all vary. Potential barriers that might influence whether VR is accepted could be specific to the setting, providers, and patients for which the VR is being used [16]. Accordingly, widely variable uptake has been reported in prior studies [6,17,18]. Thus, it is difficult to infer, from the current literature, how acceptable VR might be in a particular situation.

In this study, we evaluated the feasibility of an immersive VR experience for patients admitted to one of 2 ICUs at a single institution. We hypothesized that patients with critical illness in the ICU would be interested in experiencing immersive VR; patients and staff would encounter minimal barriers to its use; and that VR usage would be associated with improvements in qualitative and quantitative accounts of mood, anxiety, and well-being.

Methods

Study Design and Setting

We performed a prospective, mixed methods, nonrandomized feasibility study of patients with critical illness using immersive VR headsets. The study was conducted in 2 ICUs (a 25-bed medical ICU and a 16-bed cancer-specialty ICU that cares for both medical and surgical critically ill patients with cancer) at a single institution in Salt Lake City, Utah, United States. Reporting follows the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidance for observational research (Multimedia Appendix 1)[19].

Ethical Considerations

The study was approved by the University of Utah Institutional Review Board (00170975). Patients were individually consented with a waiver of the requirement for written documentation of consent. Patients were not offered compensation for participation. Deidentified data were recorded in case report forms that were later digitized for analysis.

Recruitment

Patients who were potentially eligible for study inclusion were identified by attending physicians after daily rounds on days when study staff were available for enrollment. To be included, patients needed to be 18 years or older, admitted to the ICU, free from delirium [20] (as assessed by their providers, nurses, and able to pass an additional attention screen), and able to consent on their own behalf. Exclusion criteria included severe visual or auditory impairments (eg, legal blindness or deafness), isolation precautions for infection, recent condition that could be potentially exacerbated by VR (eg, seizure, uncontrolled nausea, traumatic brain injury, history of psychosis, or admission for a mental health crisis), or other craniofacial injury prohibiting headset use. Additionally, patients under current use of an orofacial mask to deliver positive airway pressure ventilation were excluded as the mask precluded headset use; however, intubated patients, patients receiving high-flow nasal cannula, and patients receiving oxygen via a regular face mask were eligible to participate.

After patients were identified as potential candidates, nursing staff were approached to identify any conflicting patient-care tasks (eg, physical therapy or travel for diagnostic testing or procedures). Patients were then approached about whether they were interested in trying an experimental immersive VR therapy. Patient demographics, reasons for admission, and comorbidities were assessed by chart review of clinical notes. All patients who were identified as potential research participants by their attending physicians were screened for inclusion and approached if eligible.

Experimental Protocol

Participating patients were presented with 3 visual analog scales (1-10) asking them to rate their current overall well-being, level of anxiety, and level of pain. Preintervention heart rate signals were recorded using a BIOPAC MP160 system for 5 minutes prior to VR initiation (Figure 1).

Figure 1. Experimental setup, as demonstrated by study personnel. Two laptops were used to ensure the adequacy of monitoring, project the real-time virtual reality experience of the patient to troubleshoot any technical issues or adverse effects, and to transcribe interview responses after the experience. The Meta Quest headset was chosen out of several possibilities owing to the lack of fabric components to facilitate cleaning after use.

Patients were offered 1 of 3 commercially available VR experiences delivered by a Meta Quest Pro headset (Meta): an urban travel experience (YouTube VR; Google LLC), a nature experience (Nature Treks VR; GreenerGames), or a synthetic landscape experience (TRIPP). In all 3 scenarios, the experiences involved passive exploration of the environment and did not involve use of the hand controllers (Figure 2). Patients planned to use the VR headset for at least 5 minutes, with an option to continue for up to 15 minutes if desired. Physiologic recording was continued for 5 minutes after VR use was complete.

After completing the VR experience, 5 minutes of postintervention vital signs recording and visual analog scale assessments of well-being, anxiety, and pain were administered. These scales were modeled on the Visual Analog Mood Scale [21], Numeric Visual Analog Anxiety Scale [22], and Verbal Numerical Rating Scale for pain [23], respectively (Multimedia Appendix 2).

Lastly, a semistructured qualitative interview was conducted to elicit feedback. A moderator guide (Multimedia Appendix 3) consisting of open-ended questions aimed at understanding the patient's overall experience using the VR headset was administered by a trained researcher. The responses for each participant were transcribed concurrently by 2 researchers in individual Microsoft Word documents. The participant responses were deidentified to maintain patient confidentiality.

Figure 2. Screenshots from the virtual reality experiences. Patients chose between one of the following experiences: YouTube VR (Google LLC; top panel), Nature Treks VR (GreenerGames; bottom left panel), or TRIPP (TRIPP Inc; bottom right panel).

Data Analysis

The qualitative data from the semistructured interviews were analyzed using thematic analysis, a 6-phase method for organizing, identifying, and summarizing patterns and themes [24]. In the first phase, known as data familiarization, researchers carefully reviewed, extracted, and organized the textual data in Microsoft Excel. The second phase involved generating initial codes for the data using a grounded theory approach, which explores participants' attitudes, beliefs, norms, and processes to develop hypotheses from the data rather than testing preexisting hypotheses [25]. In the third phase, the assigned codes were aggregated to uncover underlying patterns, themes, and subthemes. Phases 4 and 5 focused on reviewing, refining, and defining these themes, subthemes, and codes. Finally, in phase 6, the results of the thematic analysis were summarized and reported.

A sample size of 20 participating patients was targeted in accordance with rule-of-thumb guidance for a pilot study emphasizing qualitative assessment and protocol feasibility [26]. Descriptive statistics of participants and nonparticipants in VR were used to describe the population of interest. For physiologic signals, the first 2 minutes of pre-VR recording were compared to the first 2 minutes after the VR experience. Kubios automatic beat detection software was used to preprocess the heart rate data [27]. Heart rate variability was characterized by the square root of the Baevsky stress index (SI) [28]. Pre-post comparisons of vital sign data and mood assessments were performed using paired 2-sided *t* tests. Statistical analyses were performed using Stata version 18 (StataCorp) and the code is openly available on GitHub [29].

Results

Patients were enrolled between November 8, 2023, and February 6, 2024. A total of 35 patients were identified as potential candidates and approached, 20 (57%) of whom agreed to participate in the VR experience (Figure 3). Comorbidities and reasons for ICU admission mirrored those of the general ICU population (Table 1).

Characteristics of participants and nonparticipants are listed in Table 2. The age of participants (mean 61, SD 17 years) did not differ significantly (*P*=.33) from that of nonparticipants (mean 54, SD 22 years); however, nonparticipants were significantly more likely to have previously used VR (4/15 vs 1/20; *P*=.005).

Among the 20 patients consenting to participate, 19 completed at least 5 minutes of the VR experience (1 did not begin VR due to uncontrolled pain, but completed the pre-VR baseline data collection) and 18 completed all study assessments (1 had competing care needs prior to the interview). Participants used VR for a mean of 10 (SD 3) minutes. Among the 19 participants who completed the experience, 10 (53%) chose the travel experience, 5 (26%) chose the nature experience, and 4 (21%) chose the synthetic experience. No cybersickness or other adverse events occurred.

Among the 17 patients with valid heart rate data (1 patient had an excess artifact), the mean heart rate prior to initiation of the VR experience was 86.1 (SD 11.8) beats per minute (bpm), which decreased by 1.1 (95% CI 0.3-1.9; *P*=.008) bpm by the end of the experience. Mean heart rate variability, based on the SI, was 40 (SD 23) seconds^{-2} at baseline and decreased by 5.0 (95% CI 1.5 to 8.5; *P*=.008) seconds^{-2}.

At baseline, participating patients reported moderate overall well-being (mean 6.5, SD 2.1 on a 1-10 visual analog scale with 10 being the best; n=20), anxiety (mean 4.0, SD 2.8 with 1 indicating no anxiety; n=20), and pain (mean 3.9, SD 2.8 with 1 indicating no pain; n=20). Overall mood improved by a mean of 1.8 points (95% CI 0.65-3.0; *P*=.002; n=19) from baseline, anxiety decreased by 1.7 points (95% CI 0.8-2.7; *P*=.001; n=19), and pain decreased by 1.3 points (95% CI 0.53-2.1; *P*=.003; n=19) after use of immersive VR (Figure 4).

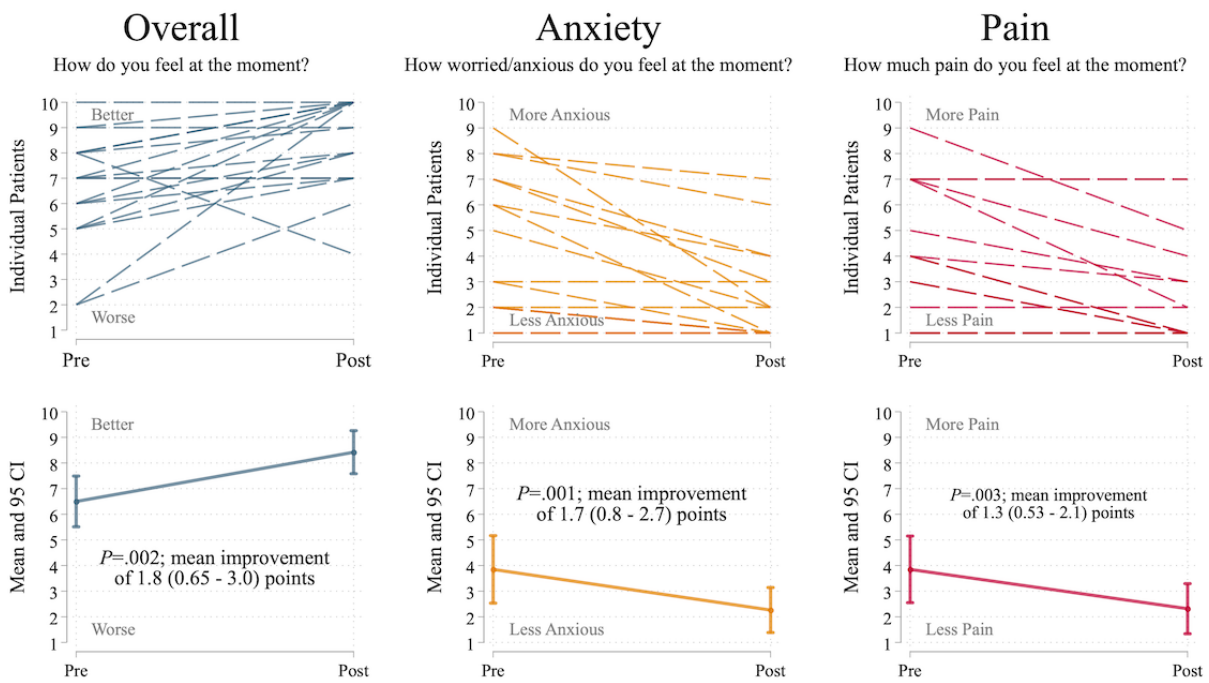
Prior VR use, n (%)	4 (57)	1 (6)	.005

Figure 4. Overall mood, anxiety, and pain scores before and after use of immersive virtual reality. All scores were assessed using visual analog scales (see Multimedia Appendix 2) on a 1-10 scale, with 10 being best for overall mood and 1 being best for anxiety and pain. The paired t test was used for comparisons and 95% CIs of the mean change are presented in parentheses.



Five themes were commonly mentioned in the post-VR interviews (Table 3). Use of the VR headset to view relaxing scenery content was met with approval by all patients. Patients had a variety of positive responses with use of the VR headset, which was described as "good," "easy," "enjoyable," "comfortable," and "pleasant." These responses indicate overall acceptance and satisfaction.

Patients also identified potential benefits of VR in alleviating symptoms of anxiety and depression. Many reported a reduction in feelings of anxiety, nervousness, and isolation, suggesting a positive impact on mental well-being. Several patients highlighted that the VR intervention helped distract them from their current pain symptoms. The immersive nature and engaging VR content enabled patients to briefly "forget" about their pain and discomfort. The VR environment was described by patients as "calming," "relaxing," and "meditative." The opportunity to escape the ICU environment and immerse themselves in nature or travel scenery was highly valued, contributing to a sense of relaxation and calm.

Lastly, most patients reported having no problems using the VR headset. A few patients reported experiencing slight discomfort with the headset weight and difficulty seeing the side visuals. No patients reported motion sickness or claustrophobia.

Table 3. Themes and representative quotes from interviews after immersive virtual reality (VR) use among patients in the intensive care unit.

Theme	Representative quote
Acceptance of the VR system	"It was comforting, it was easy, from start to finish it's so calm, it felt so fast. I don't mind wearing it longer. it was my first time using it, I was amazed." [P18]
Improvement in mental health symptoms	"I think will help someone like me, facing what I face, sitting here for all days, waiting for my surgery, being anxious, not having anything to do, and not being allowed to eat or drink. I really appreciate you guys showing up. It really helps me." [P20]
Distraction from pain symptoms	"I forgot about the pain, some of it is there. I feel relaxed and comfortable, it took me out of my mind and I'm able to focus on the virtual world, I like what I see, it's so beautiful." [P09]
Feelings of relaxation, calmness	"Mostly the calmness, being calm helps you deal with your physical issues better, and the visual experience has a lot of benefits, it helped me forget that I have clog in my lung." [P16]
Problems using the VR headset	"No, don't have any problem with it, it could be lighter with the headset. The side part it's a bit blurry, but the other it's good. It will be good to wear my glasses." [P12]

Discussion

Principal Findings

In this feasibility study of commercially available immersive VR use among critically ill patients, we found that most patients did not have prior experience with VR technology but had high levels of interest and acceptance of the technology. Participants commented on VR's potential to alleviate cognitive and emotional symptoms. Changes in heart rate variability were consistent with increased relaxation. Only minor technical challenges and no severe adverse effects were noted.

Comparison to Prior Work

Prior work has explored the potential for immersive VR for several ICU use cases [1]. However, this previous work reported widely variable rates of uptake and hinted at a "digital divide," where older patients may be less interested in new technology [30]. In contrast, we found high levels of participation among patients of all ages. Thus, VR might be considered for study even in settings that frequently care for older adults. We found that patients who had previously used VR were less likely to participate in our study. However, this might indicate that the novelty of the experience drove participation in this feasibility study. Interest may improve in prior users if VR were offered as a validated treatment. Only a minority of patients who did not participate gave reasons related to the VR itself.

After use, several participants commented on the potential of the therapy to address anxiety and foster relaxation or calmness. This was corroborated by the improvement in vital sign correlates of relaxation, such as improved heart rate variability. Some [6], but not all [18], prior studies of VR have shown consistent changes in vital signs.

Participants also highlighted the potential of VR to distract from pain, which is consistent with current guidance from the Society of Critical Care Medicine that recommends consideration of "cybertherapy [VR]" for this purpose [31]. The high usability scores and low rate of technical challenges with "off-the-shelf" commercially available options suggests that extensive customization is not a prerequisite for use. Furthermore, we did not observe claustrophobia, nausea, or "cybersickness" in any patients. Cybersickness may be less common with more modern VR headset technology that minimizes latency [32] and discordance between virtual and actual head positioning [33], which could explain why this was not encountered in our study. In contrast to prior work suggesting that nature scenes may maximize relaxation [15], travel was the most frequent VR experience choice among our participants. The potential for VR to enable "escape" from the ICU was also frequently mentioned in qualitative interviews.

Strengths and Limitations

Strengths of this study include the assessment of both quantitative and qualitative dimensions of the VR experience, which both support the feasibility and potential utility of using VR in this group. In addition, there were few exclusion criteria and thus the sample of patients is expected to broadly represent characteristics of critically ill patients without delirium. Lastly, we demonstrated and reported an off-the-shelf and replicable experimental setup that investigators can use as a starting point for future studies.

However, several limitations also deserve mention. First, nonrepresentative sampling of research participants may have occurred due to only enrolling patients during select times when study staff were available. Despite exhaustive screening of patients who were identified as potential candidates during these times, we cannot fully describe what characteristics may have influenced which patients were judged to be potential candidates for the study by attending physicians. Second, there was no control group. Time trends and the influence of conversing with study staff may also contribute to changes in symptoms and vital signs, although we attempted to stabilize physiologic trends with a 5-minute run-in period and structured interview guides were used to focus the conversation. Third, prior work suggested that VR's effectiveness correlates with the degree of immersion [34], which we did not directly assess. However, we chose not to attempt to eliminate distractions to better emulate the conditions and degree of immersion expected in actual use. Fourth, our quantitative outcome scales are slightly modified from previously validated work, and thus the reported effect sizes should not be compared to other interventions or established minimally important differences. Lastly, the uptake of VR may differ when it is offered as a treatment for specific conditions as opposed to offering the opportunity to help assess feasibility, particularly among patients who have previously used the technology.

Future Directions

This work has several important implications for the study of VR in the ICU. We used commercially available technology and found that the sessions were acceptable to patients. This suggests that customization of either software or hardware is not necessarily required for some VR use cases. Furthermore, we found high interest among critically ill patients. Lastly, we encountered minimal disruptions to patient care or study protocols, with 95% of the patients completing the experience and 90% completing all study assessments. This suggests that protocols to study the impact of VR can be integrated into usual ICU care with little impingement on clinical workflows. Evaluation of the usability in patients excluded from the current work, such as those with mild delirium or more severe emotional symptoms, could help establish the potential of studying immersive VR in additional high-risk populations.

Conclusions

We found that a relatively short session of off-the-shelf immersive VR is acceptable to critically ill patients; resulted in improved pain, anxiety, and overall mood scores; and did not result in side effects or present major technical challenges. This work suggests that studies on the effect of VR on patient-relevant outcomes in the context of critical illness are feasible. Investigators can consider VR study protocols that do not involve substantial technology customization or large changes to patient care workflows.

Abstract

Background: The misuse and overuse of antibiotics accelerate the development of antimicrobial resistance (AMR). Serious games, any form of games that serve a greater purpose other than entertainment, could augment public education above ongoing health promotion efforts. Hence, we developed an evidence-based educational serious game app—SteWARdS Antibiotic Defence—to educate players on good antibiotic use practices and AMR through a game quest comprising 3 minigames and interaction with the nonplayer characters.

Objective: We aimed to evaluate the effectiveness of the SteWARdS Antibiotic Defence app in improving the knowledge of, attitude toward, and perceptions (KAP) of appropriate antibiotic use and AMR among the public in Singapore.

Methods: We conducted a 2-arm parallel randomized controlled trial, recruiting visitors aged 18-65 years from 2 polyclinics in Singapore. Intervention group participants had to download the SteWARdS Antibiotic Defence app (available only in English and on the Android platform) on their smartphones and complete the quest in the app. Participants took half a day to 2 weeks to complete the quest. The control group received no intervention. Knowledge questions on antibiotic use and AMR (11 binary questions) were self-administered at baseline, immediately after the intervention, and 6-10 weeks post intervention, while attitudes and perception questions (14 three-point Likert-scale questions) were self-administered at baseline and 6-10 weeks post intervention. We also collected participants' feedback on app usage.

Results: Participants (n=348; intervention: n=142, control: n=206) had a mean age of 36.9 years. Intervention group participants showed a statistically significant improvement in mean knowledge score (effect size: 0.58 [95% CI 0.28-0.87]) compared with controls after accounting for age, educational level, and exposure to advertisements on antibiotics and AMR. Intervention participants also showed a statistically significant improvement in mean attitude-perception scores (effect size: 0.98 (95% CI 0.44-1.52)) after adjusting for marital status and race. A majority of participants agreed that the "SteWARdS Antibiotic Defence" app improved their awareness on antibiotic use (135/142, 95.1%) and AMR (136/142, 95.8%). About 73.9% (105/142) of the participants agreed that the app is easy to use, 70.4% (100/142) agreed that the app was enjoyable, and 85.2% (121/142) would recommend the app to others.

Conclusions: Our educational serious game app improves participants' KAP on appropriate antibiotic use and AMR. Public education apps should be engaging, educational, easy to use, and have an attractive user interface. Future research should assess the effectiveness of interventions in facilitating long-term knowledge retention and long-lasting behavioral change.

KEYWORDS

serious game application; randomized controlled trial; antimicrobial resistance; antibiotic use; public education; mobile phone

Introduction

The World Health Organization declared antimicrobial resistance (AMR) as one of the top 10 global public health threats in 2019 [1]. Antibiotic-resistant bacteria can cause human infections that are harder to treat, leading to higher medical costs, decreased work productivity, and increased mortality [2-4]. By 2050, AMR is projected to cause 10 million annual deaths and up to US $100.2 trillion in economic losses worldwide if nothing is done to slow its progression [5]. The widespread misuse and overuse of antibiotics, often driven by the public's lack of knowledge regarding appropriate antibiotic use and AMR, contribute to AMR progression [6,7].

The need to educate the public on appropriate antibiotic use and AMR is apparent, as better knowledge of antibiotic use was found to be associated with favorable antibiotic attitudes, which lowered the odds of expecting and receiving an antibiotic prescription [8]. Despite yearly public outreach [9] and multiple national educational campaigns on antibiotics and AMR [10], misconceptions about antibiotics—such as believing that antibiotics treat viral infections—continue to persist among the Singaporean population [7,8]. Traditional efforts to educate the public on antibiotic use and AMR have shown ambiguous effectiveness [11,12]. Hence, the lackluster effectiveness of existing efforts to prevent antibiotic misuse and overuse provides an impetus to explore novel public education methods beyond traditional modalities (eg, posters and pamphlets) [13].

Serious games have emerged as a promising tool for health education and health promotion across various fields recently [14]. This learning modality encompasses online and offline tools that use gamification—the use of game-playing elements—to provide an enhanced learning experience. Studies have shown promise of serious games in improving the short-term health knowledge, attitudes, and beliefs of young people, but the studies were too heterogeneous to prove the efficacy of this learning modality [15,16]. There were fewer serious games studies with older adults, but a web-based serious game co-designed with members of the public to raise pancreatic cancer awareness found a statistically significant improvement of pancreatic cancer awareness [17].

Serious games have also been used to promote good antibiotic use behaviors [16,18]. Preliminary evidence of serious games interventions on antibiotic use and AMR has shown promise in improving the knowledge of appropriate antibiotic use [16,19]. However, these studies were primarily focused on children and students. Adults have greater access to antibiotics and are more likely to pass down antibiotic use behaviors to the younger generation [13]. Hence, it is essential to educate young adults on appropriate antibiotic use. Existing studies also limited participants to a controlled environment with restricted playing time and may not fully capture real-world behavior. Furthermore, many studies overlooked the importance of long-term knowledge retention. The paucity of high-quality randomized controlled trials (RCTs) in the real-world setting highlights a pertinent gap in the evidence base of serious games for public education.

Singapore offers an excellent environment for evaluating serious game applications (apps) given its high smartphone penetration rate (92%) [20] and emphasis on digital transformation [21]. Hence, we developed an evidence-based serious game app—"SteWARdS Antibiotic Defence"—to deliver adult education on appropriate antibiotic use and AMR and aimed to evaluate its effectiveness in improving knowledge of, attitude toward, and perceptions (KAP) of antibiotic use and AMR in Singapore. We also sought user feedback on the "SteWARdS Antibiotic Defence" app.

Methods

Study Design

We conducted a parallel 2-arm RCT with a 6- to 10-week follow-up period. Participants in the intervention group had to download and complete the quest in the "SteWARdS Antibiotic Defence" app on their smartphones, while controls received no intervention.

Study Setting

We recruited patients and their caregivers from 2 government-funded primary care clinics (ie, polyclinics) in Singapore. Recruitment occurred from January to March 2023, and follow-up was completed in early June 2023. The 23 polyclinics in Singapore manage 20% of Singapore's primary health care needs by providing subsidized services such as medical treatment for acute and chronic conditions, vaccinations, and health education [22]. Participants seen at the polyclinics mainly have acute conditions that are managed outside the health care setting. Hence, while our study recruitment and baseline data collection occurred in the policlinics, the study intervention and follow-ups were administered outside the health care setting.

Eligibility Criteria

Participants were 18-65 years of age, had access to an Android smartphone, and were English literate. We excluded those with visual or cognitive impairment, not proficient with smartphone apps, and those unable to install Android mobile apps from the study.

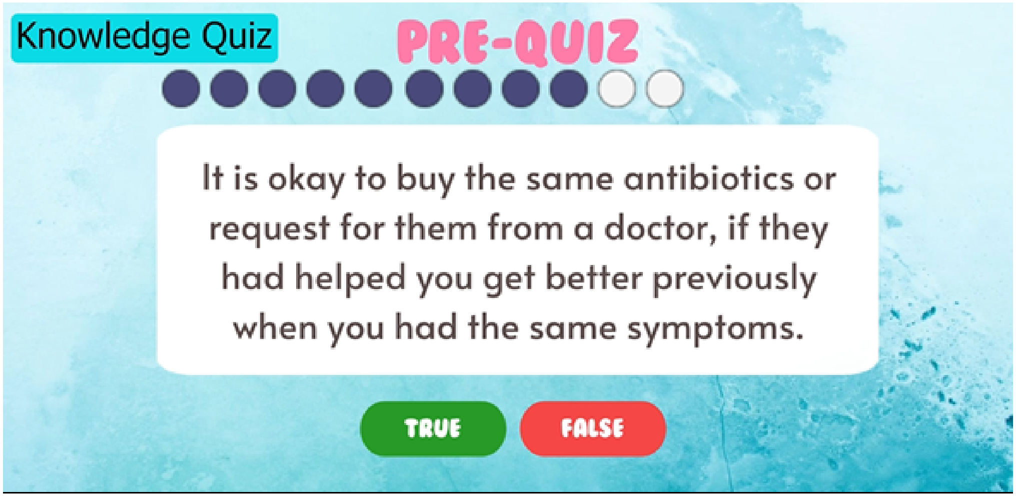
Intervention

App Development

The "SteWARdS Antibiotic Defence" app is an evidence-based serious game mobile app developed by the study team, in collaboration with Temasek Polytechnic (a public tertiary institution in Singapore), to educate the public on appropriate antibiotic use and AMR. Players learn about appropriate antibiotic use and effective methods to recover from uncomplicated upper respiratory tract infections by interacting with the nonplayer characters (NPCs) releasing bite-sized information and playing the minigames in the app. We derived the educational content in the app from a rigorous review of knowledge gaps [7,8,23], antibiotic guidance [24], and inputs from health care professionals. The in-app messages were also adapted to the local context to ensure their relevance to players [25]. A few knowledge questions in the postgame and postintervention surveys were reverse scored to reduce to learning effect on knowledge gains. The bite-sized messages and knowledge questions can be found in Tables S1 and S2 in Multimedia Appendix 1.

The pre- and postgame knowledge questions were embedded at the beginning and the end of the quest to reinforce knowledge retention (Figure 1). Completing the 11 baseline knowledge questions is a prerequisite to proceed to the minigames while completing the postgame knowledge questions is a prerequisite to fulfill the requirements of the intervention. Players are allowed to play the minigames repeatedly once they pass the level, but they can complete the pre-post survey only once. There is an in-app WhatsApp helpline for participants to contact the study team should they encounter technical difficulties. The feedback form link is also embedded in the app and appears after the completion of the postknowledge survey. Study team members (data collectors) provided intervention group participants with a onetime unique code to access the app during recruitment. The unique code allowed us to track the pre-post knowledge survey responses, time spent on the app, and interactions with the NPCs anonymously. We did not analyze the time spent on the app due to glitches that affected data quality.

Figure 1. An example of a knowledge question embedded in the app. Participants are expected to complete 11 preintervention knowledge questions, followed by the game quest and 11 post–intervention knowledge questions to complete the intervention.



Game Components

There are 3 "worlds"—the "Supermarket," "Park," and "Train station"—that lead to the minigames in the app. Each "world" comprises 2 NPCs and a minigame. The supermarket is linked to the Tower Defence game; park is linked to the Match3 game; and train station is linked to the Endless Runner game (Figures 2-5).

Figure 2. Interaction with a nonplayer character (NPC) at the park. Bite-sized messages on good antibiotic use practices were released through interactions with the NPCs. The rightmost NPC leads to the Tower Defence game.

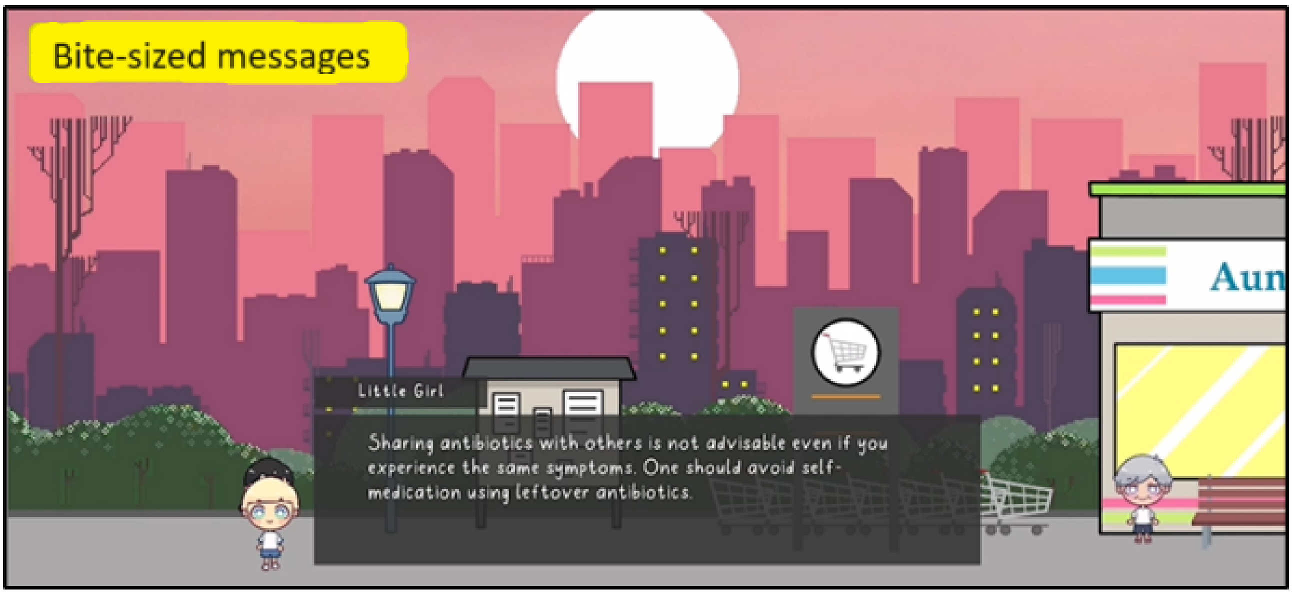


Figure 3. The Tower Defence game consists of 9 levels. The top figure shows the game interface with C-Stin turrets and the super bug (level 9). The subsequent figures show the messages released at the beginning of level 9 to teach players about the concept of antimicrobial resistance. Players have to choose the appropriate turrets and strategically place them at appropriate locations to effectively target their enemies (bacteria or viruses).

Figure 4. The Endless Runner game can be accessed via the train station (picture on top). The game reinforces the message that antibiotics are effective only against bacteria and not viruses. Players collect coins while running and use the antibiotic gun or immunity gun to shoot at bacteria or virus obstacles, respectively. Coins collected from the Endless Runner game can be used to purchase turrets in the Tower Defence game.

Figure 5. The Match3 game can be accessed via the park (picture on top). The game educates players on good health habits by focusing on sleep hygiene, nutrition, immunization, and physical exercise. Players are required to match 3 or more similar tiles within a specific time limit to successfully clear each of the 10 levels. Bite-sized messages are released before the start of each game to remind players of maintaining a healthy lifestyle.

There are 9 levels in the Tower Defence game to teach players about antibiotics and AMR. The first 2 levels teach players that antibiotics are effective against bacteria and the next 2 introduce the concept that antibiotics are bacteria-specific. Levels 5 and 6 educate players that antibiotics are not effective against viruses, levels 7 and 8 are reinforcements of previously taught concepts, and the last level educates players on antibiotic resistance by introducing a superbug that requires an expensive antibiotic (turret) to cure (kill the superbug). Players have to earn coins by passing Tower Defence levels and playing the Match3 and Endless Runner games.

The Endless Runner game is accessible via the train station. The game reinforces the message that antibiotics are effective only against bacteria and not viruses. Players collect coins while running to purchase turrets in the Tower Defence game, and use the antibiotic gun to shoot away bacteria obstacles and the immunity gun to shoot the virus obstacles.

The Match3 game is accessible via the park. The game educates players on good health habits by focusing on sleep hygiene, nutrition, immunization, and exercise. Players are required to match 3 or more similar tiles within a specific time limit to successfully clear each of the 10 levels.

Further details of the design and principles of the "SteWARdS Antibiotic Defence" app can be found in our published protocol [25]. Individual participants were followed up according to recruitment schedule from the point of recruitment. Participants took between half a day to 2 weeks to complete the intervention.

Outcomes

The primary outcome of interest was the change in KAP scores of antibiotic use and AMR. The secondary outcome was the level of user satisfaction for the "SteWARdS Antibiotic Defence" app. Primary outcomes were assessed for the intervention and control groups at baseline, immediately post intervention (intervention group only), and 6-10 weeks post intervention (from baseline for controls) via self-administered questionnaires. Knowledge was measured via 11 True/False questions, while attitudes and perceptions were measured via 14 questions on a 3-point Likert scale. Details of the KAP questionnaire are available in our published protocol [25]. For the intervention group, satisfaction with the "SteWARdS Antibiotic Defence" app was measured with 4 questions on a 5-point Likert scale and the reason(s) for recommending or not recommending the app to others, and suggestions for improvement were obtained via open-ended questions upon quest completion.

Sample Size

Assuming an effect size of 0.334 (95% CI 0.260-0.407) based on other serious games studies [18], we estimated a minimum sample size of 142 per group to detect a significant change in the knowledge score at a power of 80% and an a level of .05. We initially planned to recruit 200 participants per arm to account for a 30% attrition rate. We later increased the recruitment numbers to 240 per arm to account for a 40% attrition rate as we observed higher-than-expected dropout rates.

Study Procedures

Recruitment occurred on weekdays during the polyclinic's opening hours. Staff members of the polyclinics were trained to recruit participants in their respective polyclinics. The data collectors would walk through every level of the polyclinic systematically to recruit participants daily. We also displayed digital recruitment posters around the polyclinics, so that interested visitors could contact the study team. However, only 2 participants contacted the study team via digital posters.

Data collectors approached the patient or the visitor nearest to them who seemed to fall in the eligible age category (18-65 years of age) to explain the study while systematically walking around the polyclinic. Next, the data collectors explained the study to the persons they approached and informed them of the possibility of being randomized into either the "survey group" (control) or the "app and survey" (intervention) group. Informed consent was obtained from interested participants before asking participants to pick a card to determine the group assignment. Participants knew which group they were assigned to as the intervention group participants were asked to download the app after their demographic data was collected. Baseline data collection occurred after randomization because the pre-post knowledge questions were built into the app. We collected participants' KAP responses and demographic data at baseline and reimbursed them a small fee for completing the baseline surveys. All participants received the same amount of reimbursement at the baseline. Reimbursement was tiered to a higher value for the follow-up surveys to motivate participants toward task completion.

Baseline Data Collection

The baseline data collection process differed slightly between the intervention and control group participants. Intervention group participants had to complete the Attitudes-Perception demographic questionnaire on an iPad and install the "SteWARdS Antibiotic Defence" app on their smartphones. The data collector then provided the participant with a unique code to gain access to the app. Upon logging into the app, participants had to complete 11 baseline knowledge questions, followed by a walk-through of the basic features of the app. Controls completed the KAP and demographic questionnaire on an iPad.

Control Group Follow-Up

A study team member (ie, data collector) sends participants a detailed WhatsApp message 6 weeks after their recruitment date to inform them to complete the postintervention KAP questionnaire. The study team member sent a reminder if participants did not complete the questionnaire 2 weeks after the first WhatsApp message.

Intervention Group Follow-Up

Participants had to complete the "SteWARdS Antibiotic Defence" game quest and satisfaction survey and inform the study team via WhatsApp upon intervention completion. Six weeks after participants complete the intervention, a study team member sends a detailed WhatsApp message to inform them to complete the postintervention KAP questionnaire. A study team member reminded participants who did not complete the quest 2 weeks after recruitment and 2 weeks after sending the first KAP WhatsApp message.

Withdrawals and Loss to Follow-Up

Participants who became uncontactable during the study period were classified as loss to follow-up cases while those who indicated that they wished to be withdrawn from the study were considered as withdrawn cases. Withdrawn cases were asked to uninstall the app and were not further contacted.

Randomization

Eligible participants were 1:1 block randomized into the intervention or control group. Each block comprised 2 intervention and 2 control allocations. Participants determined their allocation by picking cards in the block, which was reset after all cards were drawn.

Blinding

Participants were not blinded to the intervention as the data collectors had to explain the "SteWARdS Antibiotic Defence" app to participants assigned to the intervention group. Apart from the data collectors, all other study team members (including the data analyst) were blinded to the group assignment.

Data Analyses

We initially planned to take the intention-to-treat approach in analyzing the study data but eventually took the per-protocol approach, as our app usage data showed that participants who did not complete the game quest had too few interactions with the app to derive any benefit from the intervention. We standardized the total Knowledge and Attitude-Perception scores to 100% to illustrate the pre-post changes in scores. Correct answers are coded as 1 while wrong answers are coded as 0. Similarly, the "correct" attitudes are coded as 1 while neutral and "incorrect" attitudes are coded as 0.

Chi-square tests and Mann-Whitney *U* tests were used for univariate baseline comparisons. Weighted least squares regressions (weighted on preintervention scores) were used to assess the effect of the intervention on knowledge and KAP scores. The best regression model was chosen based on the lowest Akaike Information Criterion. All statistical assumptions were checked to ensure the accuracy of analyses. STATA (version 15; StataCorp LLC) was used for all statistical analyses.

Participant feedback was analyzed qualitatively using thematic analysis. OJT telephoned participants to elaborate on any ambiguous feedback and categorized the feedback into themes. ZH reviewed and discussed the categorization with OJT until a consensus was reached.

Ethical Considerations

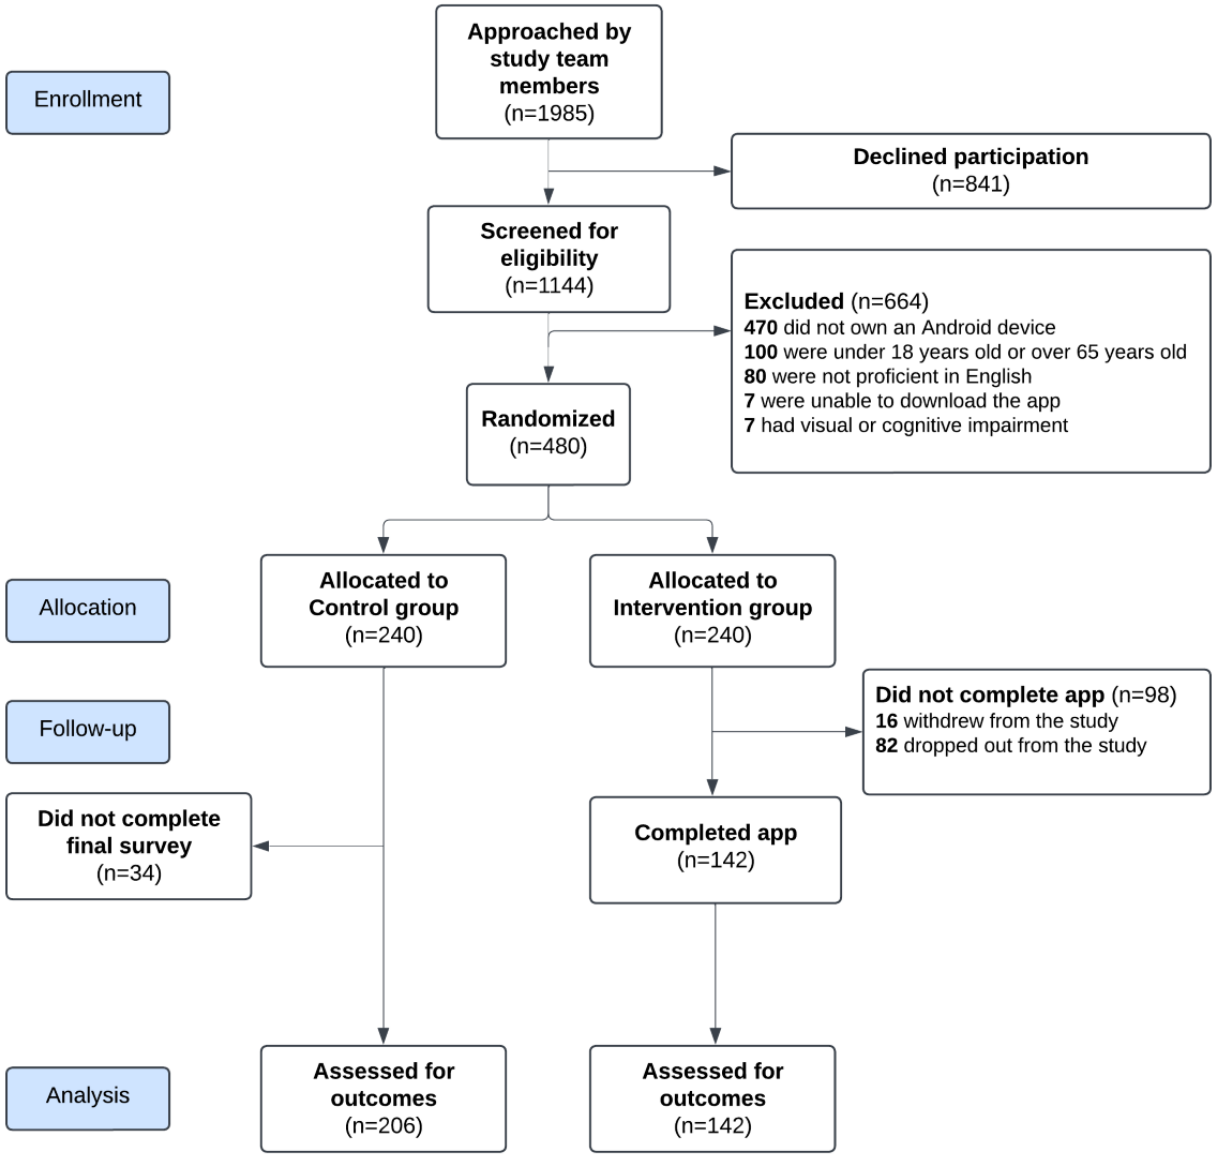
This study was approved by the National Healthcare Group Domain Specific Review Board (2022/00479) in Singapore. Informed consent was obtained from participants after the data collector had fully explained the study to them. Each participant was given a unique research ID linked to their personal details (eg, name and contact details). Only National Healthcare Group Domain Specific Review Board–approved study team members have access to participant data. All identifiable information is stored in password-protected files in the institutions' server. Data collected from the surveys and app contained only the participants' research IDs. Participants were reimbursed SGD 5 (US $3.82) for completing the baseline and demographic survey, SGD 10 (US $7.64) for completing the postintervention survey, and SGD 25 (US $19.10) for completing the app intervention and satisfaction survey (intervention group participants only).

Results

Participant Flow

We approached 1985 patients and visitors of polyclinics for 3 months, and 57.6% (1144/1985) of patients consented to take part in our study. Of these consenting participants, 41.1% (470/1144) of them did not own an Android phone, 8.7% (100/1144) did not meet our age requirements, 7.0% (80/1144) of them were not proficient in the English language, 0.6% (7/1144) of them had difficulty downloading the app, and 0.6% (7/1144) of them had visual or cognitive impairment. We block-randomized 42.0% (480/1144) of participants who were screened for eligibility into 2 study arms. Of these randomly assigned participants, 85.8% (206/240) of them in the control group and 59.1% (142/240) of them in the intervention group completed the study and had their outcomes assessed. About 40.8% (98/240) of intervention group participants did not complete the game quest (16 withdrew; 82 dropped out) in the app (CONSORT [Consolidated Standards of Reporting Trials] flowchart shown in Figure 6).

Figure 6. CONSORT (Consolidated Standards of Reporting Trials) flow diagram of a 2-arm randomized controlled trial conducted on participants recruited from government-funded primary care clinics between January 2023 and March 2023 in Singapore. A total of 1985 people were approached, 1144 were screened for eligibility, and 480 were recruited into the study and randomized equally into the control or intervention group. The outcomes of 142 intervention participants and 206 controls were eventually assessed.



Recruitment

Recruitment occurred between January 2023 and March 2023, and follow-up was completed by early June 2023. We ceased recruitment when we achieved 240 participants per arm.

Baseline Data

Table 1 shows participants' baseline characteristics. The randomization produced comparable groups as there were no significant between-group differences in participants' sociodemographic characteristics at baseline. Participants had a mean age of 36.9 (SD 12.2) years. Our participant profile fits Singapore's population profile in terms of ethnicity (252/348, 72.4% Chinese; 61/348, 17.5% Malay; and 24/348, 6.9% Indian), education level (128/348, 36.8% had tertiary education), and housing type (275/348, 79.0% residing in conventional public housing flats). There were also no significant between-group differences in the mean baseline knowledge score of 8.4/11 (SD 1.6), but the attitude-perception score was significantly higher in controls (mean 9.6, SD 2.6) than in intervention participants (mean 8.8, SD 3.0). In addition, 60.1% (209/348) of participants had no exposure to advertisements on antibiotic use at baseline.

The randomization produced comparable groups as there were no significant between-group differences in participants' sociodemographic characteristics at baseline. Our participant profile fits Singapore's population profile in terms of ethnicity and housing type.

Table 1. Baseline characteristics of the randomized controlled trial participants recruited from government-funded primary care clinics between January 2023 and March 2023 (N=348).

Baseline characteristics of respondents	All participants	Intervention group (n=142)	Control group (n=206)	*P* value
Sociodemographic factors				
Age (years), mean (SD)	36.9 (12.2)	35.9 (12.0)	37.6 (12.3)	.21
Sex, n (%)				.64
Male	181 (52.0)	76 (53.5)	105 (51.0)	
Female	167 (48.0)	66 (46.5)	101 (49.0)	
Race, n (%)				.79
Chinese	252 (72.4)	106 (74.7)	146 (70.9)	
Malay	61 (17.5)	23 (16.2)	38 (18.5)	
Indian	24 (6.9)	8 (5.6)	16 (7.8)	
Other races	11 (3.2)	5 (3.5)	6 (2.9)	
Educational level, n (%)				.24
Tertiary education[a]	128 (36.8)	47 (33.1)	81 (39.3)	
Nontertiary education	220 (63.2)	95 (66.9)	125 (60.7)	
Marital status, n (%)				.36
Married	169 (48.7)	65 (45.2)	101 (49.3)	
Unmarried	178 (51.3)	77 (54.2)	104 (50.7)	
Housing, n (%)				.98
HDB[b] 3-room flat and below	81 (23.3)	33 (23.2)	48 (23.3)	
HDB 4 or 5-room flat	194 (55.8)	80 (56.3)	114 (55.3)	
Above HDB 5-room/private property	73 (21.0)	29 (20.4)	44 (21.4)	
Knowledge, attitude, and perceptions on antibiotics and AMR[c]				
Advertisement on antibiotic use, n (%)				.34
Had seen advertisements	139 (39.9)	61 (43.0)	78 (37.9)	
Had NOT seen advertisements	209 (60.1)	81 (57.0)	128 (62.1)	
Knowledge score, mean (SD) (maximum score: 11)	8.4 (1.6)	8.5 (1.6)	8.3 (1.7)	.16
Attitude-perception score, mean (SD) (maximum score: 14)	9.3 (2.8)	8.8 (3.0)	9.6 (2.6)	.004

[a]Tertiary education: university and above.

[b]HDB flat: flats developed by Singapore's public housing authority.

[c]AMR: antimicrobial resistance.

Change in Knowledge Score

The mean standardized knowledge score improved from 77.6% at baseline to 82.4% postgame and 83.5% 6-10 weeks post intervention among intervention group participants, while controls had a modest improvement of 75.4% from baseline to 78.1% at 6-10 weeks post baseline (Figure S1 in Multimedia Appendix 1).

The multivariable regression analyses (Table 2) showed that intervention group participants had greater improvement in knowledge than controls (between-group differences: 0.58, 95% CI 0.28-0.87) after accounting for age, educational level, and exposure to advertisements on antibiotics and AMR.

Table 2. Multivariable weighted least squares regression analysis of the association between the intervention and knowledge score at 6-10 weeks postintervention.

Model variables	Outcome: 6-10 weeks of postintervention knowledge score		
	Effect size (95% CI)	*P* value	VIF[a]
Randomization group[b] (reference: control)			
Intervention	0.58 (0.28 to 0.87)[c]	<.001	1.04
Knowledge			
Baseline knowledge score	0.24 (0.17 to 0.32)[c]	<.001	1.08
Age group (years; reference: 18-25 years)			
26-35	–0.75 (–1.19 to –0.31)[c]	.001	1.91
36-50	–0.43 (–0.90 to 0.03)	.07	2.49
51-65	–0.45 (–0.99 to 0.08)	.09	2.05
Marital status (reference: not married)			
Married	–0.32 (–0.67 to 0.03)	.07	1.51
Education status (reference: nontertiary education)			
Tertiary education	0.77 (0.45 to 1.09)[c]	<.001	1.13
Advertisement on antibiotics and AMR[d] (reference: have not seen advertisements)			
Have seen advertisements	0.39 (0.09 to 0.69)[c]	.01	1.05

[a]VIF: variance inflation factor.

[b]Intervention group participants had greater improvement in knowledge than controls after accounting for age, educational level, and exposure to advertisements on antibiotics and AMR.

[c]*P*<.05.

[d]AMR: antimicrobial resistance.

Change in Attitude-Perception Score

The mean standardized attitudes-perception score improved from 62.6% at baseline to 77.7% post intervention among intervention group participants, while controls had a modest improvement of 68.9% from baseline to 71.9% post intervention (Figure S1 in Multimedia Appendix 1). The proportion of intervention group participants with the "correct" attitudes and perceptions increased for all 14 statements post intervention (Figure S2 in Multimedia Appendix 1). However, intervention group participants continue to have misconceptions about antibiotic use after completing the game quest. The proportion of participants with correct responses for the statement "I need antibiotics to recover from serious symptoms from the common cold and flu" increased from 29.6% (42/142) pre- to 46.5% (66/142) postintervention, and for "I need antibiotics if I continue to have flu symptoms after two weeks" increased from 22.5% (32/142) pre- to 38.7% (55/142) postintervention.

The multivariable regression analyses (Table 3) showed that intervention group participants had greater attitudes-perception improvement than controls (0.98 [0.44-1.52]) after accounting for marital status and ethnicity.

Table 3. Multivariable weighted least squares regression analysis of the association between the intervention and attitude-perception scores at 6-10 weeks postintervention.

Model variables	Outcome=6-10 weeks of postintervention attitude-perception score		
	Effect size (95% CI)	*P* value	VIF[a]
Randomization group[b] (reference: control)			
Intervention	0.98 (0.44 to 1.52)[c]	<.001	1.30
Attitude-perception			
Baseline attitude-perception score	0.46 (0.39 to 0.53)[c]	<.001	1.26
Education status (reference: nontertiary education)			
Tertiary education	0.56 (–0.13 to 1.26)	.11	1.67
Ethnicity (reference: Chinese)			
Malay	–2.86 (–3.56 to –2.15)[c]	<.001	1.84
Indian	–1.28 (–2.19 to –0.36)[c]	.006	1.71
Others	–0.19 (–2.10 to 1.72)	.85	1.03
Marital status (reference: not married)			
Married	–1.39 (–1.99 to –0.78)[c]	<.001	1.67

[a]VIF: variance inflation factor.

[b]Intervention group participants had better attitudes-perception improvement than controls after accounting for marital status and ethnicity.

[c]*P*<.05.

App Satisfaction

The majority of participants agreed that the "SteWARdS Antibiotic Defence" app improved their awareness on antibiotic use (135/142, 95.1%) and AMR (136/142, 95.8%). About 73.9% (105/142) of the participants agreed that the app is easy to use, 70.4% (100/142) agreed that the app was enjoyable, and 85.2% (121/142) would recommend the app to others (Table 4).

Table 4. Satisfaction in using the "SteWARdS Antibiotic Defence" app (N=142).

App satisfaction	Responses, n (%)
User experience[a]: How far would you agree that the app:	
Improved awareness on antibiotic use	135 (95.1)
Improved awareness on antimicrobial resistance	136 (95.8)
Is easy to use	105 (73.9)
Is enjoyable to use	100 (70.4)
User satisfaction	
Would recommend the app to others	121 (85.2)

[a]User experience was measured on a 5-point Likert scale. We report the proportion of respondents who agreed with the statements on user experience. The majority of participants agreed that the "SteWARdS Antibiotic Defence" app improved their awareness on antibiotic use and AMR. More than 70% agreed that the app is easy to use, enjoyable, and would recommend the app to others.

Participants who would recommend "SteWARdS Antibiotic Defence" found the app user-friendly, fun, enjoyable, and interesting. Some participants also lauded the app's unique learning modality and felt that the intervention addressed an important public health topic, raised their awareness of AMR, and improved their knowledge on appropriate antibiotic use (Table S3 in Multimedia Appendix 1).

> *It provides information about antibiotic resistance in an easy to understand, engaging way.*

> *It is much more engaging compared to reading or [looking] through long videos.*

Participants who would not recommend the app mainly had a poor user experience and were frustrated with technical difficulties in navigating the app. Some technologically astute players found the game boring, repetitive, and unfulfilling.

> *There were technical issues that made completing the game annoying.*

One participant found no value in recommending the app to friends or family member working in health care. Those who found the games difficult to play (mostly older adults) or experienced usability issues (eg, small fonts) also expressed dissatisfaction with the intervention.

Seniors may not be able to understand how to play the games.

Suggestions for App Improvement

Suggestions to improve the quality of “SteWARdS Antibiotic Defence” include the following (Table S4 in Multimedia Appendix 1):

Refining Game Mechanics

Participants pointed out that the minigames should focus on reinforcing concepts the study team intended to teach. For example, 1 minigame leans toward self-care instead of teaching about antibiotics use and AMR. Some participants also suggested improving the game’s instructional clarity, calibrating the in-game economy to optimize the game’s difficulty level, and increasing the number of interactive elements.

The upgrades in the Tower Defence Game is overpowered and makes it too easy.

Let users know how much the coins earned from “endless runner” are worth. This ties into the other game “tower defence” because you need coins to build the towers.

Enhancing the User Interface

Participants suggested having a consistent art style, larger word fonts to cater to older adults, and graphics with a closer resemblance to bacteria and viruses.

Maybe the educational message displayed before each game can be read out.

The 3D games can have better art style to match with the other 2D games and environment.

Having More App Features

Suggested app features include adding music and sound effects within the minigames, allowing players to create personal profiles, and in-app game demonstrations.

More sound effects would be nice.

Bug Fixes

Participants suggested to improve the app’s responsiveness, sensitivity, speed, and fixing the glitches.

Developer to look into the app responsiveness and the graphics.

Discussion

Main Findings

We evaluated the effectiveness of an evidence-based serious game mobile app in improving the KAP of appropriate antibiotic use and AMR among Singapore residents. To our knowledge, this is the first RCT assessing the effectiveness of a serious game mobile app intervention for public education on appropriate antibiotic use and AMR. We also assessed the effectiveness of the app in short-term knowledge retention at 6-10 weeks post intervention, which has often been overlooked. Furthermore, we assessed the app in a real-world context in the community and not in the controlled environment of an experimental setting.

We observed a statistically significant effect size of 0.58 (95% CI 0.28-0.87) in knowledge improvement, which concurs with other serious game studies on chronic disease management among young people [26] and healthy lifestyle promotion [27]. However, a similar Singapore study on dengue prevention observed significant improvements of participants’ knowledge, attitudes, and practices from baseline but no between-group mean differences [28]. The difference in observations is likely attributed to the exposure of relevant information sources among controls in the dengue study, which attenuated the effects of the app intervention. Tertiary-educated adults were positively associated with higher postintervention scores. They may fare better at learning the more difficult AMR concepts as studies have shown that AMR concepts are hard to teach. Participants with no or limited understanding of the etiology of antibiotic resistance would face difficulty connecting AMR with antibiotic misuse [29]. Furthermore, misconceptions about antibiotic use are generally hard to rectify.

We also observed a statistically significant effect size of 0.98 (95% CI 0.44-1.52) in attitude-perception improvement with the “SteWARdS Antibiotic Defence” app. Other studies have found mixed results in the effectiveness of serious games in improving the adoption of healthy behaviors, such as fruit and vegetables intake among adolescents [15]. The effectiveness of serious games in changing attitudes and perceptions are hard to measure as studies are often multifaceted. Therefore, it is essential to have well-designed interventions targeted at the correct population, well-accepted by participants, and with attainable goals for interventions to be successful. While we recruited participants between 18 and 65 years of age, the app was originally developed for young adults as this group of people was found to have the lowest knowledge in antibiotic use and AMR [7].

Our “SteWARdS Antibiotic Defence” app received an overall positive rating, but the ratings should be interpreted with caution as the satisfaction survey was only completed by participants who finished the game quest in the app. It is unclear whether participants dropped out of the intervention due to dissatisfaction with the app or a lack of time to complete the quest. Other studies assessing the effectiveness of serious games in health education have observed high satisfaction among participants [30,31]. However, there is limited evidence on the satisfaction with health education delivered via serious games in the general population and even fewer studies report participant satisfaction. Hence, the feedback and suggestions we gathered from participants are valuable in identifying population-specific shortcomings of the intervention and informing app enhancements that could increase the success of intervention scale-ups.

Despite a modest improvement in KAP scores in the intervention group, improved health literacy may not translate to desired behavioral change [13,32]. Health literacy interventions have led to improved health outcomes in some studies, but the links between health literacy improvement and behavioral change have not been established with higher-quality studies [33].

Effective interventions are also integral to attaining successful behavioral change. One way to improve the learning outcomes, suggested by our participants, is to weave the intended learning concepts into the game mechanics rather than displaying informational text boxes for players to read. Such enhancements would possibly improve user engagement and lead to better learning outcomes [34].

A few limitations exist in our study. First, measurement errors in KAP scores might occur if intervention group participants had requested their friends or family members to help with study completion. Nonetheless, controls could also have had help in completing the postintervention survey. Therefore, any bias which attenuates the intervention's true effect is likely toward the null. Second, there is a ceiling effect for participants with near-perfect baseline scores, which could attenuate the positive effects of the intervention. Third, we randomized participants prior to baseline data collection because the knowledge questions were embedded in the app. Fourth, there may be a learning effect in the intervention group as these participants completed the knowledge questionnaire 3 times. Hence, the positive effects observed in the intervention group could be a combination of the serious game and learning effect from the immediate postgame survey. Including a study group with a traditional form of learning (eg, brochures) may enable us to assess the effect of the serious game app more accurately. Finally, we included only attendees at 2 government-funded primary care clinics (polyclinics). Despite the limitations in recruitment, the sociodemographic distribution of our participants is representative of the Singaporean population. Hence, our findings are generalizable to the rest of the country.

In addition, we noticed several older adults rejecting study participation due to a lack of interest in completing the mobile app quest. Their lack of interest implies an additional effort to change their mindsets, and serious game interventions may not be the best modality for educating older adults on public health issues. Reminders were also integral in driving the app completion rate. Hence, the actual uptake rate may be lower in the population. Future research should assess the effectiveness of interventions that facilitate long-term knowledge retention and long-lasting behavioral change in antibiotic use and AMR [35].

Conclusions

Our educational serious game app improves participants' KAP on appropriate antibiotic use and AMR. Public education apps should be engaging, educational, easy to use, and have an attractive user interface. Interventions should also aim to achieve long-term knowledge retention and long-lasting behavioral change.

Acknowledgments

ZH and OJT had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. The study team would like to acknowledge Tan Soon Peng, Khoo Jin Rong, Siti Shazwani Binte Sadimin, Nur Atiqah Binte Surya Akmaja, and Karthiga Natarajan for their assistance in data collection and study administration. We would also like to thank the staff and student interns from Temasek Polytechnic's School of Engineering and School of Informatics & IT for their contribution in maintaining the "SteWARdS Antibiotic Defence" app and database during the study. This work is supported by the National Centre for Infectious Diseases (National Centre for Infectious Diseases Catalyst grant FY2022HZ).

Data Availability

Deidentified data that support the findings of this study are available on request from AC or ZH.

Disclaimer

The research presented in this paper is solely the responsibility of the authors and does not reflect the views of the funder.

Authors' Contributions

ZH codeveloped the app, conceived the manuscript, obtained the catalyst grant, analyzed the data, and drafted the manuscript. OJT administered the study, analyzed the data, and drafted the manuscript. WET provided inputs to the study design and support for running the trial. AC codeveloped the app and provided inputs to the study design of the trial. All authors critically reviewed the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Sleep games are an emerging topic in the realm of serious health game research. However, designing features that are both enjoyable and effective at engaging users, particularly university students, to develop healthy sleep habits remains a challenge.

Objective: This study aims to investigate user preferences for 3 sleep game prototypes, that is, Hero's Sleep Journey, Sleep Tamagotchi, and Sleepland, and to explore their popularity and perceived utility in promoting sleep health.

Methods: A mixed methods approach was used in this study. Quantitative and qualitative data were collected through a co-design workshop involving 47 university students. Participants were presented with storyboard cards of game features and were asked to provide an overall rating on each game, as well as ratings for individual features. They were also encouraged to provide free-form comments on the features and suggest improvements. In addition, participants were asked to express their preferences among the 3 games regarding which game they would most like to play and which one they found most useful for promoting sleep health.

Results: Surprisingly, while Hero's Sleep Journey was the most popular choice among participants, Sleep Tamagotchi was perceived as the most beneficial for improving sleep health. Relevance emerged as an overarching theme in the qualitative data analysis, with 3 interconnected dimensions: psychological relevance to users' personal lives, logical relevance to sleep health, and situational relevance to users' circumstantial context. We discussed how the 3 dimensions of relevance address the autonomy and relatedness constructs outlined in the self-determination theory and proposed 3 design recommendations.

Conclusions: Our serious sleep game prototypes demonstrated the potential to engage university students to develop healthy sleep hygiene. Future sleep game designs should aim to create a sense of relevance to users' personal lives, sleep health goals, and situational contexts. Rather than a one-size-fits-all approach, it is essential to develop a wide range of game genres and features to cater to diverse users. Aligning game features with sleep health goals and educating users on the design rationale through sleep knowledge are also important aspects. Furthermore, allowing users to customize their game experience and manage technology boundaries is necessary to nurture a sense of control and autonomy in the process of forming good sleep hygiene.

Introduction

Background

Sleep plays an important role in sustaining physical and mental health [1]. Not having enough good sleep is associated with an increased risk of cardiovascular diseases, metabolic disorders, temporary and permanent cognitive impairment, and mental health issues [2,3]. However, attaining adequate sleep is often challenging for many university students, and poor sleep quality is frequently associated with poor sleep hygiene in this population [4-7]. Sleep hygiene encompasses 4 interconnected dimensions: establishing a regular sleep-wake cycle, creating a nighttime routine, optimizing the sleep environment, and cultivating healthy daily habits [8]. Sleep research has demonstrated that behavior changes targeting sleep hygiene positively impact sleep health among clinical populations [8,9], indicating the potential application of behavior change technology for promoting healthy sleep behavior. Despite this potential, the development of such technologies in the domain of sleep health has generally been limited in focus and scope [10].

There have been previous attempts to incorporate playful elements into improving sleep hygiene to make the process more engaging and effective [11]. These efforts can be broadly categorized into tangible approaches and mobile apps. Tangible approaches use physical tools or materials, such as worksheets [12], tactile game boards [13], and aroma tokens [14]. In addition, various alarm clocks have been introduced with designs to awaken users in effective and creative ways. Examples include Ruggie (Windustries Limited), which requires users to step on it; Gun O'Clock (Bandai Namco), which necessitates shooting a target; and Clocky (CLOCKY, LLC) and the Helicopter Alarm Clock (Toyo Trading), which must be chased to deactivate. These approaches challenge users by incorporating active tasks to turn off the alarm.

With respect to mobile apps, many attempts have been made to develop various sleep games. Some focus on relaxation by integrating peaceful and calm elements within the game design (eg, Harmony [Logitech Europe SA], SpinTree 3D [Tabasco Games], and Sheep Sleep [Superpea Ltd]), while others guide users through relaxation techniques such as breathing exercises (eg, Loona [KEYi Technology Co, Ltd] and Mindllama Breathe Sleep better [Llama Luna Apps]). Certain games promote mindfulness regarding bedtime routines [15], screentime before bed [16], and daily habits related to sleep [14] or incentivize the maintenance of healthy bedtime habits (eg, Sleep Town [Seekrtech] and Pokémon Sleep [The Pokémon Company]). Despite this variety, most of these apps function as alarm clocks, offering playful methods to wake users up and regulate their sleep patterns. They typically present specific missions (eg, Early Bird Alarm Clock [ONEYEAR], Sleep as Android: Smart alarm [Urbandroid Team], AlarmClock Xtreme [Agilesoft Resource], ChallengeAlarm [Nicole Ocean], Alarmy [Delight Room Co, Ltd], and TurboAlarm [Francisco Javier Castaño Gómez]) or incorporate minigames, such as simple shooting games or puzzles, requiring players to achieve certain goals to deactivate the alarm (eg, AlarmMon [Malang Studio Co Ltd], Vmons [Vmons App], Wakey [Kanetik], AlarmBuddy [Alarm Buddy], and Unicorn Alarm [NETIGEN Apps]).

While there are numerous games and gamified apps to enhance sleep hygiene, there remains significant room for improvement. First, as noted earlier, existing solutions are primarily designed for mobile apps or custom tangible artifacts. At this point, smartwatches offer unique advantages over other types of technology, such as reduced blue light exposure, timely interventions, and the capacity to track different health indicators [17,18] and sleep metrics [19], with reasonable accuracy [20]. Nevertheless, surprisingly little work has explored the potential of smartwatch games for promoting sleep hygiene.

Second, current sleep games and gamification systems primarily target the nighttime routine and, to a lesser degree, the regularity of sleep-wake cycles and sleep environment optimization. Only 1 study has explored the design space surrounding daily activities, particularly caffeine intake, for sleep hygiene improvement [14]. Targeting daytime activities that promote better sleep represents a vast design space, including strategies, such as receiving early morning sunlight exposure, having meals early, and avoiding late naps or caffeine consumption close to bedtime [21-25]. Furthermore, it is still unclear how incorporating daily activities to improve sleep health will be received by users of sleep hygiene technologies.

Finally, most current services aim to improve sleep quality through gamified apps rather than actual games that provide a fully playful and immersive experience. The potential of games for behavior changes and persuasive technologies is well documented [26] but surprisingly underexplored in the domain of sleep health.

This Study

This work seeks to explore how smartwatch-based sleep health games are perceived by potential users and could in turn be used as effective tools for improving sleep hygiene. We achieve this by tapping into the unexplored dimensions of sleep hygiene games using a participatory design approach, aiming to provide insights and design implications that contribute to the future development of serious sleep hygiene games.

Methods

Conceptualization and Design of Smartwatch Sleep Games

Overview

In prior work, we adopted a co-design approach that gathered a cohort of university students to participate in the brainstorming and design of sleep health technologies targeted at addressing the sleep health needs of this population more accurately [4]. A total of 51 university students participated in 3 co-design workshops. Thematic analysis of the qualitative data generated 9 themes, including health tracking, sleep environment optimization, sleep literacy, community, recommendation, gamification, generative artificial intelligence, materializing sleep with learning, and personalization. For more details on the workshop and resulting initial design insights, refer to the study by Liang et al [4]. Building on these design insights and evidence-based sleep health knowledge, we developed 3 low-fidelity prototypes of smartwatch sleep games that addressed various themes identified as important by the participants of the initial workshop (Figure 1). The game features for each prototype and their designs are described in more detail in the subsequent sections.

Figure 1. Prototype mockups of the 3 smartwatch sleep games.

Hero's Sleep Journey: Power Up Hero With Your Sleep to Fight Monsters

Hero's Sleep Journey (HSJ) focuses on leveraging the powerful motivational effects of role playing and avatars [27-29]. It features a hero avatar as the main visual theme and is centered on adventure and mission completion. Users play as a hero who grows stronger through good sleep hygiene and fights monsters to protect their village. Some of the core game features are summarized in Textbox 1.

Textbox 1. Summary of core game features of Hero's Sleep Journey.

Core game features of Hero's Sleep Journey

- Regain health points through sleep: players restore their hero's vitality by ensuring adequate sleep, with an emphasis on sleep duration and quality.
- Fight monsters through healthy daily habits: players fight monsters that attack the village by performing various healthy daily habits, such as exercising, walking, stretching, and so forth. Successfully defeating monsters rewards players with in-game currency, which can be used to hire additional heroes or change avatars, as well as buy accessories and weapons that can further improve their hero's abilities.
- Complete daily sleep hygiene challenges: players can complete a small number of special challenges each day to gain unique rewards for their hero, such as extra currency, exclusive weapons or accessories not available in the shop, and stat increases that can further improve their hero's abilities. Examples of special challenges include but are not limited to walking a set amount of distance, taking a certain number of steps in an hour, or reaching a specified heart rate.

Sleep Tamagotchi: Raise Virtual Pets With Your Sleep

Sleep Tamagotchi (ST) leverages the charm of a virtual pet to engage players in improving their sleep hygiene [30,31]. The central theme involves a cute digital pet that guides users in developing and maintaining healthy sleeping habits. Some of the core game features are summarized in Textbox 2.

Textbox 2. Summary of core game features of Sleep Tamagotchi.

Core game features of Sleep Tamagotchi

- Complete daily routines with pet: players can complete various daily activities with their pet, such as stretching, walking, and exercising at appropriate times of the day. These activities are proven to benefit night sleep according to sleep science studies [6,7].
- Prompting healthy sleep practices: players will be prompted with notifications and in-game animations of their pet performing desired activities at appropriate times of day or night (eg, walking, stretching, taking a bath, getting ready for bed, and sleeping).
- Customization rewards for healthy sleep practices: players earn rewards and gifts for their pet through sleeping well, maintaining a consistent sleep schedule, and forming good sleeping habits.

Sleepland: Building Village With Your Sleep

Sleepland focuses on using the motivational power of construction games, that is, games where players combine or configure objects to organize and build things [32]. Specifically, it features building construction as its main visual theme, allowing players to create and develop their own land or town. Users are tasked with the challenge of restoring a Japanese village using their *sleep power*, which is accumulated through healthy sleep hygiene activities. Some of the core game features are summarized in Textbox 3.

Textbox 3. Summary of core game features of Sleepland.

Core game features of Sleep Tamagotchi

- Engaging game narrative: A guardian spirit visits players and asks for the player's help in fixing an old countryside village so that they can have a beautiful place to watch over and protect again. The player has daily interactions with this guardian spirit and slowly learns about the village, its people, and its history over time as they progress through the game.
- Healthy sleep hygiene rewards: When players sleep, they can meet goals and reinforce healthy behaviors to gain points. Meeting goals for the first time, such as sleeping earlier or reducing screen time, will allow them to repair the village and expand its boundaries. In addition, maintaining existing healthy sleep behaviors will reward the player with in-game currency, which can be used to build within the village and customize its look.
- Repair the village: The repair stage involves fixing habits that users want to change, such as waking up earlier, sleeping earlier, reducing screen time, or drinking more water for the first time. Meeting these goals allows users to repair places and items in the village.
- Build within the village: Players can build new habits by repeating healthy behavior over time. As players build up these new habits, they receive in-game currency that allows them to build new things within the village to customize its look, layout, and feel.

Co-Design Workshop

Participants

We distributed flyers and posters around the campus of the Kyoto University of Advanced Science (KUAS). A total of 45 participants (self-identified as female participants: n=7, 16%; and self-identified as male participants: n=38, 84%) attended the workshop. The age of the participants ranged between 18 and 35 years. In total, 9 (20%) participants had prior experience using a smartwatch or wristband for self-tracking. All participants were undergraduate or graduate students enrolled in the Faculty of Engineering at KUAS during the time of the workshop.

Workshop Flow

Before beginning the main activities of the workshop, we provided an introduction to the workshop goal as well as background information on serious games, wearable sleep-tracking technologies, and sleep hygiene. Participants were given an icebreaker activity to encourage collaboration and discussion among one another. Following the icebreaker, participants were briefed on the main findings from the initial workshop and given background information about the sleep game. They were then presented with storyboard cards depicting features from all 3 prototypes. In total, 2 examples of these storyboard cards are shown in Figures 2 and 3. Each card included 4 questions on the backside: "How useful is this feature for improving sleep?"; "Would you use this feature?"; "Could anything be improved?"; and "Free comments." The first 2 questions required participants to rate the feature on a Likert scale ranging from 1 to 4, with higher ratings indicating a more positive appraisal of the feature. The last 2 questions are open-ended. Participants formed groups of 4 to 6 people to evaluate each feature of the 3 prototypes and were encouraged to openly share their feedback within their groups. Once all features were evaluated, the cards were collected.

Figure 2. Storyboard of the friendly nudge feature in Sleep Tamagotchi.

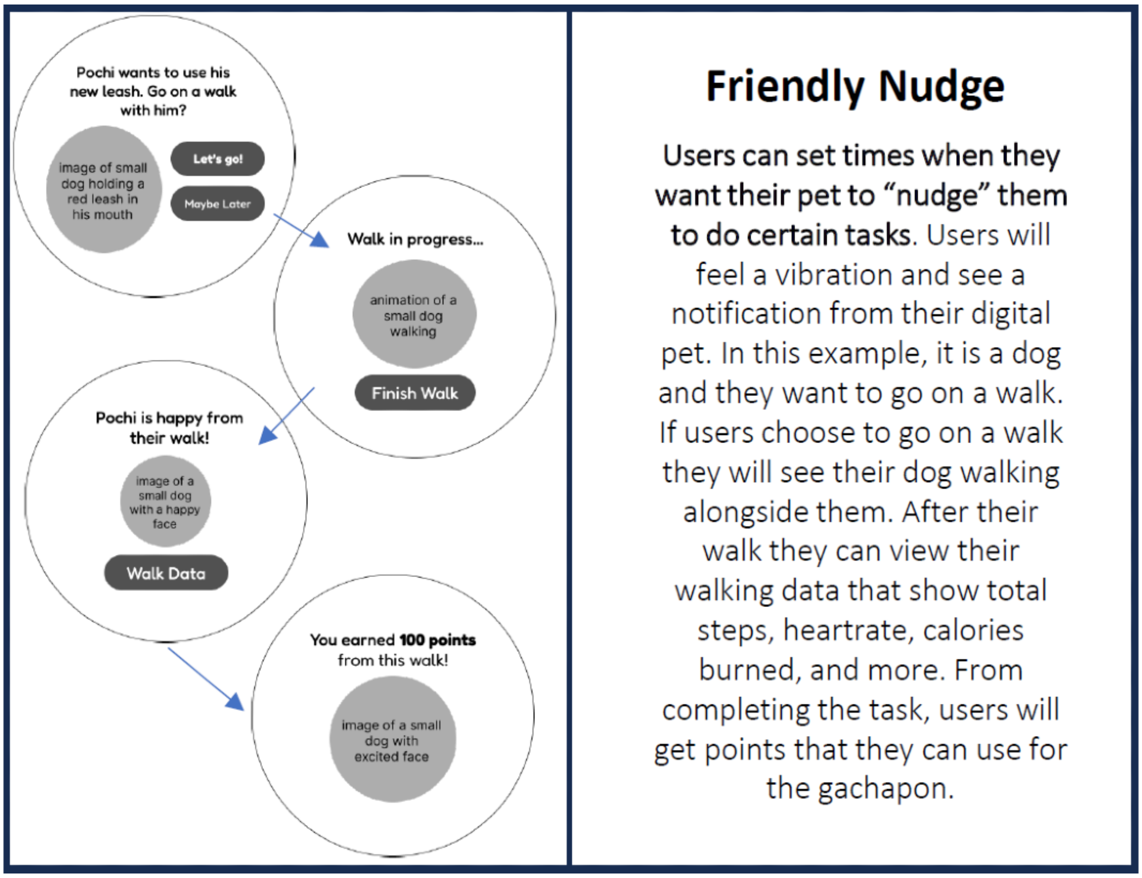

Figure 3. Storyboard of the fighting monster feature in Hero's Sleep Journey.

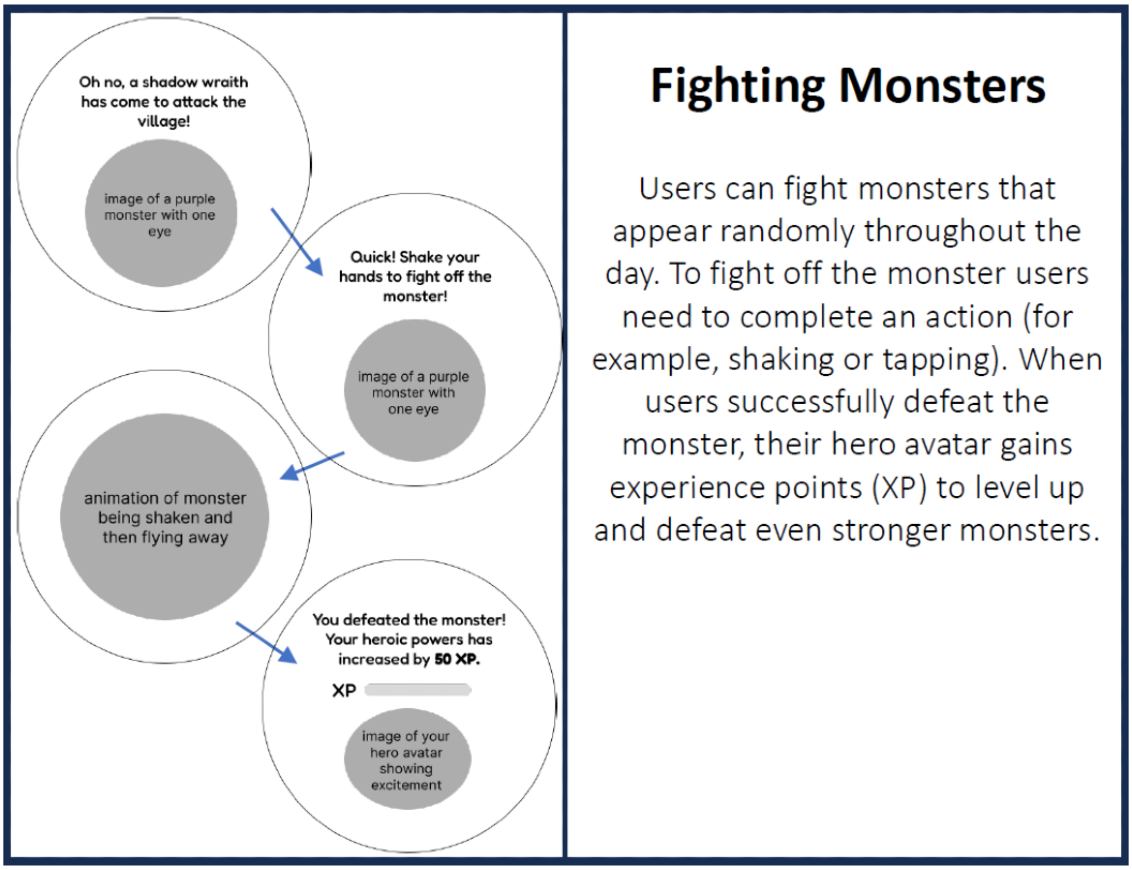


At the conclusion of the workshop, participants completed the 5-factor player traits questionnaire [33], a validated instrument with 25 items, administered in paper format. This questionnaire assessed participants' preferences for different game elements and playing styles. Using this tool provided a deeper insight into the participants' inclinations toward each sleep game. Alongside the questionnaire, participants were also surveyed about the amount of time they spent playing games per week as well as their preferences among the 3 games regarding which one they found most useful for promoting sleep health and which game they would most like to play.

Data Analysis

This study used a mixed methods approach, resulting in a comprehensive collection of both quantitative and qualitative data from the workshop. Initially, all data were collected on paper and subsequently digitalized into spreadsheets for analysis. For the quantitative data analysis, histograms were created to illustrate participants' ratings of each game's overall appraisal and individual features. The qualitative data, consisting of participants' free-form comments, were analyzed using thematic analysis. In total, 3 authors independently conducted the coding, and discrepancies were resolved through discussion. Instead of using a predefined coding schema, codes were inductive and identified iteratively by repeatedly reviewing the comments. These codes were then grouped into 8 themes, which will be detailed in the *Qualitative Findings* section.

Ethical Considerations

The study was approved by the ethics review board of Kyoto University of Advanced Science (23E04). Participants signed informed consent forms before the start of the workshop and received an Amazon gift card (approximately US $20) upon the completion of the workshop. Data were anonymized to protect the privacy of the participants.

Results

Participants

Understanding player traits is essential for designers to create games that resonate with their target audience. We received 96% (43/45) of the responses to the 5-factor player traits questionnaire. Nearly half (21/43, 49%) of the respondents primarily demonstrate the esthetics trait, highlighting their appreciation for a game's visual and auditory elements, such as graphics, sound, and art style. The second most common trait is the narrative trait (11/43, 26%), revealing their preference for complex storylines within games. In addition, 21% (9/43) demonstrated dominant social traits, reflecting their preference for social interaction during gameplay and their desire to feel connected to other players. As for game-playing hours, most respondents (31/43, 72%) reported spending a modest amount of time playing games, typically between 1 and 10 hours per week, which aligns with the global average of around 8.5 hours per week [34]. In addition, 19% (8/43) spent 11-20 hours per week, while only 7% (3/43) spent more than 21 hours per week on gaming.

Quantitative Findings

We received responses from 96% (43/45) of participants regarding their preferences for the 3 sleep game prototypes. Our results revealed a notable discrepancy between the popularity and perceived usefulness of sleep games. When asked which game prototype they would most like to use, 56% (24/43) of the respondents selected HSJ, 30% (13/43) chose ST, and only 14% (6/43) opted for Sleepland. By contrast, when asked which game prototype they found most helpful for improving sleep, 67% (29/43) identified ST, 23% (10/43) picked HSJ, and only 9% (4/43) selected Sleepland.

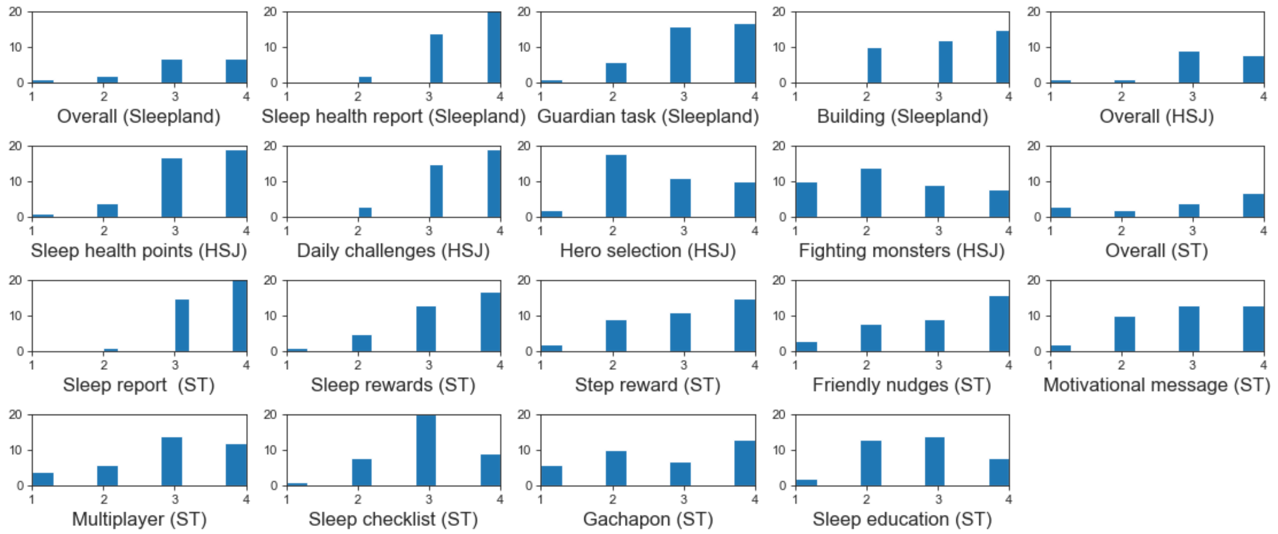
For the perceived utility of individual features, we received ratings and feedback from 91% (41/45) of participants for both Sleepland and HSJ and 84% (38/45) of participants for ST. Table 1 shows the portion of respondents who answered "yes" to the question "Would you use this feature?" The most popular features across 3 sleep games are sleep reports, sleep rewards, and daily challenges, which have a clear and direct relation to changing sleep hygiene behaviors and providing concise feedback on that progress. In contrast, the least popular features are fighting monsters and hero selection in HSJ and sleep education in ST. These features either obfuscated the focus on sleep hygiene or required extraneous amounts of effort to process.

A similar tendency was observed in the histograms of respondents' ratings for each game prototype and individual feature, as illustrated in Figure 4. Consistent with participants' willingness to use the features, the hero selection and fighting monster features of HSJ as well as the sleep checklist and sleep education features of ST received lower ratings from participants. In contrast, the sleep health report and Guardian's task features of Sleepland, the sleep health points and daily challenges features of HSJ, and the sleep report and sleep rewards features of ST received higher ratings, indicating greater appreciation for these features. Meanwhile, features such as Gachapon and motivational nudges of ST exhibited more variance in their scores.

Table 1. The proportion of respondents who answered "yes" to the question "Would you use this feature?"

Game and individual feature	Respondents, n (%)
Sleep Tamagotchi (n=38)	
Sleep report	33 (87)
Sleep rewards	32 (84)
Motivational message	27 (71)
Sleep checklist	27 (71)
Step reward	26 (68)
Friendly nudges	26 (68)
Multiplayer	25 (66)
Gachapon	24 (63)
Sleep education	19 (50)
Hero's Sleep Journey (n=41)	
Sleep health points	37 (90)
Daily challenges	34 (83)
Hero selection	26 (63)
Fighting monsters	18 (44)
Sleepland (n=41)	
Sleep health report	36 (88)
Guardian task	33 (80)
Building	31 (76)

Figure 4. Histogram of participants' ratings to the question "How useful is this feature for improving sleep health?" (1=not useful and 4=very useful). HSJ: Hero's Sleep Journey; ST: Sleep Tamagotchi.



Qualitative Findings

Thematic analysis identified 8 themes, with 2 that arose from participants' suggested improvements for each game or feature.

Game Genre Impacts the Popularity of Sleep Games

Our observations suggest that the genre of the game influences participants' perceptions of its features. Many participants who indicated their preference for HSJ were originally fans of role-playing games (RPGs), drawn to the fantasy environment embodied by the theme and storyline of the HSJ game. For instance, the participants said the following:

> *(The HSJ game) has a clear energy and having to sleep to fight is pretty cool.* [P24]

> *It's a good idea to have a role-playing game. Having a main hero character has always been the 'apple of the eye' for people in movies and games. So having a hero against a villain is a good idea for games.* [P35]

Similarly, participants who favored Sleepland were originally fond of building games, while those who chose ST felt connected to animals and pets. They said the following:

> *I love world-building games where you can create your own little corner of peace!* [P4]

> *I like gathering resources and using them to build something up, and this would be a fun way to get points and work towards a satisfying village.* [P10]

> *I really enjoy games related to pets that we have to take care of or fight for.* [P23]

Different Preferences Between Competitive and Noncompetitive Players

Another primary factor influencing participants' preferences for different sleep game prototypes was their orientation toward competitive or noncompetitive gameplay. The HSJ game distinguished itself as the most interactive game among the 3, featuring level-up mechanics and customization that appealed to competitive players. P34 noted the following:

> *The hero character is very interesting with the upgrade potential. I could make my own customizable character different from my friends.* [P34]

In addition, a few participants found HSJ useful for improving sleep due to its motivating and engaging nature. In total, 4 participants who voted for HSJ believed that the daily challenges would motivate them to "be more mindful of sleep health" and they would "try to sleep well so that the hero can win." P13 mentioned that "progress can be made much faster (in HSJ) compared to the other two (games) due to the element of competition."

Conversely, not all participants identified as competitive players. Some preferred Sleepland and ST precisely for their passive nature. Compared with HSJ, Sleepland was considered less complicated because, as P3 said, "the tasks can be automated, and it takes minimum input from the users." The pet theme of ST was also perceived as more lighthearted compared with the other 2 games, as P5 noted, "I don't think I would be a competitive sleeper, which is the requirement for Hero's Sleep Journey." Unlike HSJ, which excites players, ST causes less stress as, according to P5, "it seems like a fun app in an easygoing manner. Not too competitive. And feels like a very gently encouraging app."

Emotional Impact of Sleep Games

Participant feedback highlights the emotional impact of sleep games. Interacting with cute pets in ST seems to create an affection effect that reinforces positive behavior change by fostering a sense of companionship and mirroring behavior. Participants reported feeling connected to virtual pets, with some expressing willingness to "do anything for a cute virtual pet, even sleeping early" or "try to complete any tasks that a virtual pet gives me." Furthermore, the friendly nudge feature in ST was praised for its companionship effect, potentially enhancing users' motivation. P5 commented as follows:

> *It might be a bit boring to do walks or exercises on your own, so it would be nice to have some encouragement from a virtual pet.* [P5]

Virtual pets may also have a mirroring effect, as stated by P40:

> *When you are taking care of the animals routine, you can have a perceptive of your own routine.* [P40]

A similar effect was also noted in the HSJ game. One participant associated the healing during sleep with the healing process of the hero character, thus considering an RPG the most suited for sleep health intervention.

Nevertheless, we also observed potential negative emotions that sleep games may elicit, particularly in relation to reward features. While rewards can serve as external motivation for some participants, others expressed concerns that earning health points or completing tasks in HSJ may induce unnecessary stress. In addition, rewards based on sleep quality may inadvertently trigger rumination, since factors like the amount of deep sleep are often beyond an individual's control.

Alignment With Sleep Health Enhances Perceived Utility of Game Features

Surprisingly, the most popular game is not necessarily perceived as the most useful. While HSJ seemed to be the most popular, ST was perceived as the most useful. The primary reason for ST's perceived utility lies in its features, which are more focused on sleep health and less distractive from the sleep goal.

More than one-third (13/38, 34%) of the participants considered the ST features highly pertinent to sleep health, stating that ST "has the most sleep and helpful driven features out of the three" (P12). They acknowledged that "there are lots of features that could help me improve my sleep health even if the features or tasks might not be interesting" (P22). Sleep report and sleep education were 2 features that participants highly appraised for their potential positive impact on users' awareness of sleep health. They considered the sleep education contents useful and informative, and the sleep reports would allow users to "look back in the long run" to "analyze sleep patterns" so that "users can be in touch with this for a longer period without getting bored" (P43). These features help users stay focused on improving sleep health without overengaging with features that are not critical for sleep health. As P30 stated, "the other games will make you get distracted and prioritize your game more than your sleep."

Similarly, due to the perceived direct link to sleep, the sleep reward features in all 3 prototypes, which manifested differently as a building feature in Sleepland, a sleep health points feature in HSJ, and a sleep reward feature in ST, were highly praised by participants. In contrast, the step reward feature in ST, while also a form of reward, garnered less interest. Given the unclear relationship between step count and sleep quality improvement, participants were less inclined to engage with this feature.

Game Features Distracting From Sleep Health

We observed that some interactive features, despite being fun and engaging, were considered distracting from the goal of improving sleep health. Participants noted that the diversity of tasks in HSJ is likely to keep users engaged. P1 stated the following:

> *The range of possible tasks is the most diverse in Hero's sleep journey, so it is most likely to keep me engaged the longest.* [P1]

However, participants also acknowledged that these interactive features are not necessarily tied to improvement in sleep quality, just as one participant mentioned:

> *It looks the most fun to me. It also feels like the most interactive one. Although I don't feel like it would help improve my sleep like the other two.* [P12]

Similar complaints were noted about Sleepland by P12, "it (Sleepland) feels more like Clash of Clans than a sleep improving app."

Features Influencing Perceived Autonomy

Participants' preferences for game features were influenced by their perception of autonomy while engaging with those features. They highly valued the flexibility of tasks in Sleepland and ST, emphasizing the importance of being able to "choose their tasks" and "do them at any time" to avoid interference with their work or class schedule. In contrast, the hero selection feature in HSJ received criticism for requiring frequent user choices. Excessive customization imposed a sense of forced action that compromises autonomy. Similarly, the sleep checklist feature imposes a sense of forced action. Participants stated that they would be "too tired at the end of the day to check the list" (P12) and "people have different strategies in winding down for sleep" (P22).

The daily challenge features, including the friendly nudge feature in ST, a daily challenge feature in HSJ, and the Guardian's task feature in Sleepland, may also compromise autonomy. For example, participants found that the 10,000-step goal was too laborious and challenging to achieve, preferring apps that do not dictate their actions. P45 preferred to do things by herself, and she did not "need the app to tell me what to do." In addition, concerns were raised regarding the potential frequent notifications resulting from the daily challenge features. Participants expressed worries that these notifications could be disruptive and cause annoyance rather than motivation.

Suggested Improvements

Overview

Participants offered valuable feedback for improving the sleep games, as summarized in Textbox 4. The suggestions largely fall into 2 categories: enhancing the game experience and aligning the game with sleep health goals and outcomes. Suggestions for improvement included customization options, diverse reward structures, and integration of community features. In addition, participants emphasized the importance of aligning game features with sleep health goals, such as discouraging oversleeping and providing personalized sleep recommendations.

Textbox 4. Summary of participants' suggestions for improvement.

Suggestions for enhancing the game experience

- Avoid excessive notifications
- customization (game characters, daily challenge list, and goals)
- personalized reward (bonus rewards for streaks and higher rewards for people with a worse sleep baseline)
- community and social features
- support multisensory interaction (voice input and vibration)

Suggestions for better alignment with sleep health

- Provide personalized sleep recommendations
- align daily challenges and rewards with the day-night cycle
- discourage oversleeping

Suggestions for Enhancing Game Experience

Participants highlighted the need to maintain personal space and avoid excessive notifications, which can become intrusive and bothersome. Allowing users to customize their notification preferences, including whether and when to receive notifications, was considered essential. Customization in other areas of the game was also valued. Along the same line, daily challenges should be tailored to match a user's capability and daily routine. As P1 stated, "a nice middle ground must be found regarding the difficulty of the daily challenges so as to not demotivate the player." Diversifying game resources, such as introducing various hero and pet types and various forms of in-game currency such as gold and mana, was suggested to enhance the gaming experience. Participants also proposed the idea of assigning different heroes with unique skills that tackle a set of "daily challenges tailored to specific aspects of sleep hygiene" (P27). For example, 1 hero could "focus on exercise for better sleep," while another could "focus on sleep preparation" (P27).

Participants highly valued the sleep reward features in all 3 games but suggested that rewards should not follow a linear structure. They proposed awarding bonus points for maintaining streaks and offering higher rewards to those with a low sleep baseline as strategies to encourage consistent, healthy habits and recognize users' progress. In addition, some participants expressed interest in incorporating penalties for not adhering to good sleep schedules or neglecting daily challenges. They also appreciated the concept of progressive difficulty in the game, with the challenge levels increasing as users advanced. This approach may help maintain engagement and interest while fostering a sense of accomplishment over time.

They also advocated for more community and social features in the games, such as fostering collaboration, competition, team play, and enabling users to share or trade items with other players. For instance, 1 participant suggested allowing users to "visit and interact with other users' villages" in the Sleepland game.

Furthermore, participants valued the use of multisensory interaction. They proposed the integration of pet sounds, ringtones, and vibration patterns as effective ways to boost user engagement and immersion in the ST game.

Suggestions for Better Alignment With Sleep Health

Participants also offered a variety of suggestions to align game features with sleep health, that is, using more endogenous designs [35,36]. These proposals aim to integrate gaming experiences with healthy sleep habits and encourage users to develop better sleep practices grounded in scientific evidence in sleep research.

While recognizing the value of checking sleep statistics, participants emphasized the importance of providing personalized recommendations based on users' current sleep patterns and predicted future sleep quality. Several participants emphasized the importance of aligning daily challenges and rewards with the day-night cycle. For the Sleepland game, P35 suggested implementing a timeline for tasks, such as "sleeping only at night to gain points and exercise in the morning to earn points." P3 recommended that "sleeping during specific hours of the day should allow the hero to heal faster." To minimize distractions from the app during sleep hours, P10 proposed that "if the village is viewed during designated sleep time" in the Sleepland game, "some repairs should be undone."

Oversleeping appears to be a common issue among university students. Participants underscored the importance of discouraging oversleeping, even suggesting penalties for doing so. As P35 noted, "sleeping too much (more than 7-8 hours) should result in point deduction."

By contrast, a few participants expressed concerns about rewarding players based on sleep quality, arguing that rewards should instead focus on sleep habits and discipline, such as maintaining a consistent sleep schedule. They noted that sleep quality can be beyond a person's control, whereas habits and discipline are more manageable.

Discussion

Principal Findings

All 3 sleep games incorporate various persuasive strategies, including self-monitoring, reminders, and rewards, addressing the themes that emerged in our initial co-design workshop [4]. However, not all games or their individual features were perceived as equally useful or engaging. Our findings underscore the pivotal role of the relevance of game features in participants' perceptions of the utility of sleep games. Relevance can be broadly defined as something "important to the matter at hand." The search for relevance is a fundamental aspect of human cognition, and things are relevant to an individual when they have a positive cognitive effect [37]. The relevance of game experience has been recently explored in [38]. In the field of serious games, the importance of relevance has been studied in learning games [39,40]. Previous research has found that relevance influences motivation, adherence, and initial technology adoption. While the importance of relevance has been somewhat recognized in health games [41], no study has thoroughly explored this topic.

Through our analysis, 3 interconnected aspects of relevance emerged: relevance to users' personal experience, relevance to sleep health, and relevance to users' situational context. We mapped these 3 dimensions of relevance in sleep games to different types of relevance identified in the literature: psychological relevance, logical relevance, and situational relevance [42]. Through the lens of self-determination theory [43,44], we discuss how these dimensions of sleep game relevance can fulfill users' psychological needs, particularly autonomy and relatedness, thereby promoting healthy sleep behavior change.

Relevance of Sleep Game to Players' Personal Experience and Preferences

Overview

Participants' inclination to engage with sleep games is heavily influenced by their prior game experience and personal preferences, highlighting the importance of creating psychological relevance in the design of serious sleep games. Our findings indicate that participants preferred sleep games that aligned with their favorite game genre. For example, those fond of RPGs favored HSJ, while others attracted to pet-related themes were more inclined toward ST. Participants' preferences for sleep games were also shaped by their orientation toward competitive or noncompetitive gameplay: competitive players preferred HSJ, and noncompetitive players leaned toward ST and Sleepland.

Several participants emphasized their sense of connection to the game characters as a main reason for their willingness to engage with the game, further highlighting the importance of sleep hygiene games to create psychological relevance. In HSJ, for example, the hero healing feature serves as a metaphor for the restorative effects of sleep, framing the player's actions as instrumental in restoring the hero's vitality. Similarly, users care for virtual pets in the ST game, prompting them to reflect on their own schedules as they maintain a regular schedule for the virtual pet. This creates a digital twin effect [4], aligning with the strategy of similarity used in other health-interventional games [26]. The sense of psychological relevance reduces psychological barriers and enhances the sense of autonomy for behavior change. In contrast, the guardian's task feature in Sleepland, which involves repairing damaged villages, did not seem to foster the same association with the healing benefits of sleep for humans, possibly due to a lack of similarity and relevance between repairing a lifeless object and human recovery. The importance of establishing an emotional connection in serious games has been previously highlighted in [45-47]. Our findings contribute further evidence within the context of sleep health. Game design elements that foster psychological relevance to players' prior game experiences and personal lives, particularly those that elicit feelings of autonomy and relatedness, may be crucial to the initial adoption of sleep game technologies.

Design Recommendation 1: Diversify Game Genres and Create Relatable Characters

Sleep games need not adhere to a one-size-fits-all design. Instead, offering a variety of game genres allows users to choose those that resonate most with their preferences and personal experiences, thereby transforming the external demand for healthy sleep behavior change into a more self-determined, personally endorsed, and volitionally initiated process. Furthermore, creating game characters that users feel connected to will enhance perceptions of self-relevance and promote a sense of relatedness [48-50]. This, in turn, boosts intrinsic motivation to engage with the game and healthy behavior change.

Relevance of Sleep Game Features to Sleep Health

Overview

The second dimension of relevance for sleep games revolves around whether the game features logically contribute to improving sleep. As a form of serious game, sleep games use game design elements to influence players' behavior toward better sleep health. Aligning game design with the serious context poses a well-acknowledged challenge in serious game research [51,52], and sleep games are no exception.

Our findings indicate that perceived relevance to sleep health significantly influences the utility value of game features, which in turn leads players to feel more competent in the act of improving sleep health. Features that directly focus on sleep, such as sleep education and sleep rewards in ST, were highly regarded for their relevance and potential to improve sleep. This relevance was considered a major reason why ST could be more effective than the other 2 games. Conversely, features, such as fighting monsters in HSJ, while enjoyable, were not directly linked to sleep health and were consequently rated as the least popular among all HSJ features. Furthermore, several participants expressed concern that features irrelevant to sleep health might distract users from their sleep goals, potentially harming rather than improving sleep. This concern reflects the tension between the health care context and the entertainment nature of games highlighted in previous studies [53]. Addressing this tension requires careful alignment between the serious context and the game features following established design frameworks [41,53]. Indeed, participants made pertinent suggestions on how to better align the game design with sleep health goals, including aligning daily challenges and rewards with the day-night cycle and discouraging oversleeping.

Interestingly, we observed that the perceived utility of sleep game features does not always match their actual utility. Some features, despite having a direct positive impact on nighttime sleep supported by scientific evidence, were not perceived as relevant by many participants. Features such as the daily challenges in HSJ and friendly nudges in ST encourage users to engage in daytime activities conducive to better sleep. These activities represent meaningful behaviors for improving sleep and empower users to achieve their sleep goals. However, not all participants immediately recognized the relevance of these activities and were hesitant to engage with them. For instance, while some participants understood the connection between daytime physical activity and nighttime sleep, others did not. While goal mechanisms have been proven effective in serious games, particularly in educational settings [54], our study shows that it is equally, if not more important, to communicate the rationale behind these goals to users, particularly regarding their logical relevance to improving sleep.

We also found that perceived relevance alone is not sufficient for users to engage with a feature. Despite its perceived relevance, the sleep education feature in ST was the least popular. Instead of presenting educational content in long text, the sleep education feature could be gamified and presented in smaller chunks through gameplay, as exemplified in [55].

Design Recommendation 2: Align Game Features With Sleep Health and Help Users Understand the Rationale Behind Design

Educational content of sleep knowledge can be embedded within the game's narrative and tasks; for example, introducing a character that provides sleep tips as part of the storyline or using interactive elements, such as quizzes, minigames, and challenges that reward users with in-game benefits for learning about sleep health [55].

Relevance of Sleep Game Features to Players' Situational Context

Overview

The third dimension of relevance for sleep games involves the situational or circumstantial context of users, akin to the notion of situational relevance discussed in prior research [56]. This notion of "life context" has also become an important issue identified in recent behavior change literature [57]. A key finding of this study is that frequent game interactions during the daytime are not always welcomed, as participants' willingness to engage with those features varied across the day. While sleep games do not necessarily need to be played at night [14], it is important to maximize the situational relevance of daytime interactions to avoid compromising the sense of autonomy.

All 3 games implemented features that address daytime activities. There is a large body of evidence showing that numerous daytime activities can influence nighttime sleep [4,5], making daytime interactions a natural design target for sleep games. However, many participants expressed concerns about being disrupted by notifications irrelevant to the activities at hand, especially during classes or other busy times. Consequently, features likely to generate excessive notifications, such as friendly nudges and sleep education in ST, were rated as the least popular features among the workshop participants. Several participants mentioned that they do not need the sleep game app to dictate their actions, indicating a compromised sense of autonomy due to potentially excessive notifications.

One way to address the potential interruptions caused by excessive notifications is through boundary management [58,59], which ensures that notifications are pushed at appropriate timing and are relevant to the users' situational context. This can be achieved through direct approaches, such as user customization, or indirect approaches, such as leveraging contextual information and users' behavior patterns to determine optimal notification timing [60]. For example, many participants were reluctant to engage in sleep games immediately upon waking, as they preferred to prioritize their daily routines over gaming. This observation aligns with previous research indicating that people's acceptance of notifications varies throughout the day [61] and that they are less likely to attend to notifications in the morning compared with other times of the day [62].

Ensuring the relevance of sleep game features to users' situational context addresses their psychological needs for autonomy. Besides customizing notifications, participants expressed a desire for autonomy in completing daily challenges to gain a sense of competence. Users prefer daily challenges to be achievable rather than feeling frustrated about not being able to accomplish them. For example, instead of setting a default goal of 10,000 steps, step goals should be customizable because users may have busy schedules, prefer biking over walking, or prefer indoor exercise over outdoor walking on some days. On the basis of these findings, we propose the third design recommendation mentioned subsequently.

Design Recommendation 3: Support Boundary Management Through Manual and Automatic Customization

Allow users to choose when and how often they receive notifications. Make it possible for users to opt to receive notifications only in the morning, evening, or at specific times that suit their daily routines. Contextual information from other apps, such as calendar, GPS, and sleep profile, can be used to customize notification settings automatically, avoiding sending notifications during busy periods, meetings, or events. Providing a variety of choices and allowing users to configure a daily challenge list according to their daily schedule is another way to enhance the situational relevance of sleep game features.

Limitations

This study has several limitations. First, our participants predominantly consist of male international students enrolled in a Japanese university. As a result, the findings may not be readily applicable to other demographic groups. Second, all participants had prior experience playing video games, which could potentially limit the generalizability of our results to individuals who do not engage in gaming. Third, due to the small sample size, we were not able to quantify the associations between player traits and their preferences for sleep game features. We will expand the participant pool to include a more diverse demographic and investigate the preferences of individuals with limited or no prior gaming experience.

Conclusions

This study examined university students' preferences for 3 sleep game prototypes and their perceived utility in promoting sleep health. Results showed a notable divide between the popularity and perceived utility of the games. HSJ was favored for enjoyment, while ST was seen as more effective for improving sleep health. This highlights the potential of serious games to enhance sleep hygiene, especially when game features are perceived as relevant. Key factors influencing perceived utility include prior gameplay preferences, perceived relevance to sleep health, and avoiding excessive interactions. Our findings suggest focusing on psychological, logical, and situational relevance in game design. We recommend diversifying game genres, aligning features with sleep health, and managing technology boundaries effectively.

Acknowledgments

This study was supported by JSPS Grants-in-Aid for Early-Career Scientists (21K17670) and Kyoto University of Advanced Science (KUAS) Overseas Collaboration Grant. The authors would like to extend their gratitude to the graduate and undergraduate students at the University of California, Santa Cruz (UCSC) who assisted in prototyping the 3 sleep games, especially Bianca Villamor, Jilly Li, Mandy Cai, Bridget Ho, and Hebah Haque. The authors also thank KUAS graduate students Cleber Franca Carvalho, Kevin Kristofer Kosasih, and Prasan Priya Yapa for their help with the logistics of the co-design workshop. Finally, the author would also like to thank the workshop participants.

Abstract

Background: Digital mental health interventions could sustainably and scalably prevent and reduce loneliness in older adults. We designed an app containing 29 text-based games and a questionnaire-administering chatbot to stimulate intergenerational contact.

Objective: This study aims to evaluate the feasibility of a social gaming app in reducing loneliness among older adults by evaluating recruitment strategies, data collection procedures, and gameplay activity.

Methods: This mixed methods study recruited participants via newsletters, articles, and a social media campaign. We used semistructured interviews and descriptive analysis of questionnaire answers and game data to assess feasibility. Key measures included recruitment reach and efficiency, participant demographics, in-app activity, and app usability and engagement feedback.

Results: The social media campaign reached 192,641 potential participants, resulting in 1363 game downloads. A total of 155 participants (aged 65 years and older: n=34, 21.9% and aged less than 65 years: n=121, 78.1%) provided informed consent, yielding a conversion rate of 0.08%. The recruitment campaign focusing on distanced playful interaction had a significantly (*P*<.001) higher click-through rate (1.98%) than a campaign focusing on research participation (click-through rate=0.51%; *P*<.001). The overall conversion rate from advertisement exposure to research participation was 0.08%. Participants had a mean age of 48 (SD 16) years. The 65 years and older group averaged 70 (SD 5) years, while the less 65 years group averaged 42 (SD 12) years. Additionally, 45.2% (57/126) reported at least moderate levels of loneliness at baseline. Of the initial 554 players, 91 (16.4%) remained active after the first week, and 32 (5.8%) remained active for more than 90 days. Active participants tended to interact with those within their own age group, as indicated by a Pearson correlation of r=0.31 between the ages of the message sender and receiver. Interviews with 12 (48%) participants (aged 65-79 years; female: n=12, 83%) revealed barriers such as excessive chatbot questions and a mismatch between the target group and app design focus. Questionnaire completion rates dropped from 46% at baseline to 10% at follow-up.

Conclusions: These findings underscore the challenges of recruitment and retention for older adults in a fully digital social gaming intervention. Effective recruitment strategies and targeted app design are crucial for engagement. Based on these insights, future interventions should focus on simplified interfaces, clear guidance for gameplay, and addressing the specific needs and preferences of older adults, thereby enhancing the effectiveness of digital mental health interventions.

KEYWORDS

loneliness; digital health; serious gaming; older adults; recruitment; feasibility study

Introduction

In the Netherlands, people younger than 55 years (20%) and 95 years (62%) experience moderate to severe loneliness [1] according to the De Jong Gierveld Loneliness Scale (DJG) [2,3]. Loneliness increases with age due to social network changes, availability of family members and friends, opportunities for transportation, and health problems [4-6]. Loneliness, in turn, exacerbates these health factors [7], thus creating a negative feedback loop.

There are 2 reasons for limited robust evidence for loneliness interventions: a lack of randomized, blinded trials [8-14] and the difficulty with recruitment. Lonely participants are hard to include in studies, as people typically do not self-identify as lonely or fear the stigma of loneliness [15].

Local interventions are often not scalable without demanding vast resources and are often not transferable to other contexts [16-20]. Digital mental health interventions (DMHIs) might increase efficiency and reach, standardize data gathering, and reduce the costs of care and workforce needed [21]. Such DMHIs have been successfully used in several psychotherapeutic, cognitive remediation, and telepsychiatric interventions and applied to healthy aging and disorders such as attention-deficit/hyperactivity disorder and dementia [22]. The use of DMHIs to reduce loneliness in older adults is scarce. During the COVID-19 pandemic, DMHIs were successfully used to reduce loneliness. However, these DMHIs were not easily scalable and did not focus on strengthening the social networks of an older population [16,23,24].

Applied gaming is a type of DMHI using the idea of “serious gaming” to achieve goals other than entertainment [22]. It adds playful design and game dynamics elements to an intervention to, for example, promote engagement, enhance intervention efficiency and efficacy, and possibly induce behavioral change [25]. Social gaming, a specific form of serious gaming, stimulates the creation of friendships and social interaction [26-29] and can mitigate feelings of loneliness [29]. However, game mechanics and personal factors such as stress levels may affect individual outcomes [30,31]. For example, 1 study found that individuals playing to increase social interaction may experience less loneliness, but people playing for diversion from daily life may feel lonelier [31]. As such, social games need to be designed and evaluated purposefully, as the effect of gaming on loneliness may vary across individuals.

This study evaluated a loneliness-targeting gaming intervention co-designed with game developers, design experts, and representatives from aging communities. Our research aim was to describe the recruitment and inclusion process and search for options for improved efficiency in games for health studies.

Methods

Ethical Considerations

The local ethics committee of the Radboud University Medical Center (2020-6645) reviewed the study and judged it not to fall within the remit of the Medical Research Involving Human Subjects Act. Therefore, the ethics committee approved the study based on the Dutch Code of Conduct for Health Research and Responsible Use, the Dutch Personal Data Protection Act, and the Medical Treatment Agreement Act. Participants provided informed consent in-app before data collection. No compensation was provided to participants, and data was securely stored in a database compliant with European laws (SO 9001, 27001 and NEN 7510), ensuring privacy and confidentiality according to the Dutch Personal Data Protection Act.

Participants

The research aimed to streamline the recruitment and inclusion process and identify ways to enhance efficiency in health-related gaming studies. This study did not involve specific sample size calculations for the recruitment aim, although our original study focused on measuring social interaction through gaming. For details on the sample size calculation of the original study, see Multimedia Appendix 1 [32-34].

We recruited participants via newsletters, studies, workshops, project websites, and all project partners’ networks and social media channels (mainly through Facebook campaigns). Recruitment through the social media campaign lasted from August 2020 to February 2021 (ie, 6 months). The app remained available after the campaign ended. Recruitment efforts mainly targeted potential players aged 65 and older. However, younger players were also targeted to allow younger players to invite, assist, and play with older players. For example, we organized a gaming cocreation workshop with children and included one of the games they created in the app.

No exclusion criteria were applied to prevent in-game social network formation restrictions, allowing everyone to download the app. Participants were divided into 2 groups for analysis: older adults are those aged 65 years and older (“65+”) and younger adults are those younger than 65 years (“65–”) in accordance with the United Nations’ definition [35]. We chose 65+ as the cutoff age because this period is characterized by retirement (the average age at retirement is 65 years and 11 months [36]) and good health, often referred to as “the third age” [37]. This group is also considered well-suited for preventative measures against loneliness later in life [38].

After downloading the app, agreement to the terms of conditions was mandatory to use the app, which included sharing backend data (eg, message type and timestamp and game session information). Participants were then provided information, asked for informed consent, and administered questionnaires by a chatbot. Finally, Dutch-speaking participants 65 years or older could enroll in poststudy interviews assessing user experience regarding game and study design. For more information on participant demographics, see Multimedia Appendix 2.

Playing Together App

Development Process

The PlayingTogether ("SamenSpelen"; Games for Health) app development used an iterative design process between the research team, the game developers, and the target group (Multimedia Appendix 3).

Game Description

PlayingTogether is a photography and text-based social gaming platform on iOS and Android consisting of 29 mini-games designed to elicit personal social interaction. These games are chat groups allowing synchronous and asynchronous interaction, themed around a specific set of rules. Examples include playing Hangman ("Galgje") and exchanging photographs of objects starting with the last letter of the thing depicted in the previous photo ("Fotoslang").

User Interface (UI)

There were 2 major UI versions during this study. The first version was available at launch containing a black-and-white appearance with line art icons as game avatars. The black and white color scheme allowed less distraction regarding design and game mechanics during iterative feedback rounds with target users, as gaining feedback on these aspects was the main goal in this initial phase.

The design closely resembled commonly used messenger apps to facilitate user-friendliness, as over 70% of Dutch people aged 65-75 years used messaging apps in 2019 [39]. However, we focused game design on compatibility with all age groups to make the app more appealing to younger family members and promote inter-generational gameplay. Figures S4A-S4C in Multimedia Appendix 4 show the first version's home page, game repository, and conversational chatbot, respectively. Subsequently, according to a user voting campaign via Facebook, we introduced a new UI, as seen in Figures S4D-S4F in Multimedia Appendix 4. The updated design was developed to aim for a fun and playful feeling for all ages.

Data Collection

We collected data through semistructured interviews and the app. The app collected data through a questionnaire administering chatbot, helping to boost completion rates as participants can stay in the app to answer questionnaires in a conversational format. In addition, it provides game data by storing backend information regarding gameplay.

Recruitment Data

The numbers of impressions and clicks were stored to monitor the reach versus the effectiveness of the recruitment campaign. Impressions refer to the number of people seeing the ad, while clicks refer to the number of people clicking on the link provided within the ad.

Questionnaires

The chatbot was preprogrammed to administer 5 questionnaires at baseline. Participants started by answering a Personal Information Questionnaire (PI) containing questions regarding, for example, marital status, work status, living situation, and education. Next, a mobility score was calculated using the Life Space Assessment [40], which has been translated into several languages with acceptable validity and reliability [41,42], and more recently translated, though not yet validated, for Dutch older adults [43]. This score ranges from 0=totally bed-bound to 120=independently traveled out of town daily [44]. Next, loneliness scores were measured at baseline and repeated after 1, 2, and 3 months as the primary outcome measure by DJG, which was developed and validated in the Netherlands [2,45] and translated to several different languages later on [46]. It consists of a 6-item scale for emotional loneliness and a 5-item scale for social loneliness, with the total loneliness score being categorized into 4 levels: 0-2=not lonely, 3-8=moderately lonely, 9-10=severely lonely, and 11=very severely lonely. The Older Persons and Informal Caregivers Survey, developed and validated in the Netherlands [47,48], provided information on demographics, morbidity, quality of life, functional limitations, emotional well-being, social functioning, and health services use [47]. Finally, the Network Domain Identification and Significance (NDIS) questionnaire, developed and validated in the Netherlands [32], provided information on participants' social networks at baseline and end of participation. Participants aged 65+ had to answer all questionnaires, while younger participants only answered the PI and DJG questionnaires.

Game Data

Game data entails a session creation timestamp, a list of player IDs, session IDs, and game names. We stored message length, timestamp, sender ID, and type (text or photo) for every message sent within a session. Social network data is stored implicitly through message receivers and senders. Player IDs were linked with profile creation time at first login and, if given, their age.

Interviews

Participants who agreed to be contacted for a qualitative evaluation were asked to participate in a semistructured telephone interview in March 2021. All interviews were voice recorded and conducted by a female project member (EH) according to an interview guide (Multimedia Appendix 5) with primarily open-ended questions structured around the following main topics: barriers and facilitators regarding the app, games, and chatbot. Participants provided informed consent before their interviews, field notes were taken during the interviews, and the audio recordings were transcribed verbatim and anonymized afterward. Data saturation was reached after 12 interviews.

Analysis

Assessment of App Download Funnel

We applied A/B testing to compare social media recruitment strategies where *A* focused on participation in research and *B* focused on distanced playful interaction. Each focus was divided into 3 different emphases. For focus *A*, the emphasis was on A_1: reducing loneliness in older adults, A_2: studying the effect of gaming on valuable interpersonal contact, and A_3: the impact of gaming on well-being. Focus *B* involved the emphasis on B_1: the need to play together due to the COVID-19 pandemic, B_2: the app facilitating more family time, and B_3: encouraging play on special occasions often used for social interaction (eg, Christmas).

We used Facebook's A/B testing functionality to analyze the effectiveness of these recruitment strategies. This method randomly advertised the 2 focuses and their underlying emphases while recording their total number of impressions and the number of resulting clicks. Then, the click-through rate (CTR), that is, clicks divided by impressions, and total conversion rate (CR), that is, the total number of app downloads divided by impressions, were calculated from these numbers to measure recruitment strategy effectiveness. Finally, a *z* test for independent proportions was used to calculate whether CTRs significantly differed between advertisement focus *A* and *B*.

To assess recruitment effectiveness outside social media channels, the chatbot also asked participants how they learned about the app or study: advertisement or paper, newsletter, acquaintance, project website, social media, or other.

Assessment of In-App Participant Funnel

We assessed the total number of active profiles at critical points in the participant journey to uncover bottlenecks in app usage. This entailed evaluating the number of people who gave consent to the terms and conditions, agreed to read and provide informed consent to the questionnaire chatbot, answered the questionnaires at different time points, and sent messages.

Analysis of In-Game Collected Data

Python (Python Software Foundation) was used for a descriptive analysis of sample characteristics, usage dynamics, and social network information. The degree distributions are described using the mean, minimum, maximum, and SD. Furthermore, the median is reported with the first and third quartiles. A preliminary descriptive analysis of app effectiveness was performed by assessing DJG scores over time. Furthermore, the Pearson correlation *r* is used on message data to relate the age of the message's sender and receiver, providing an outcome between r=–1 and r=1. A value of 1 means that everyone only communicates with their own age group, –1 means that everyone avoids communicating with their own age group, and 0 implies that communication is random regarding age. When analyzing network structure, we refer to components, that is, islands of connected players in which no connections exist between players on other islands. Using these components could increase an individual's social network naturally as it provides information to introduce the individual to previously unknown friends of friends. Therefore, nonfully connected components (ie, not everyone in the component knows one another) could be used for targeted introductions and network growth.

Analysis of Interviews

The interview transcripts were coded using ATLAS.ti (ATLAS.ti Scientific Software Development GmbH) and analyzed thematically to identify relevant and overarching themes [49]. Two researchers (JJ and EH) independently coded the interviews, discussing codes and differences afterward.

Results

Overview

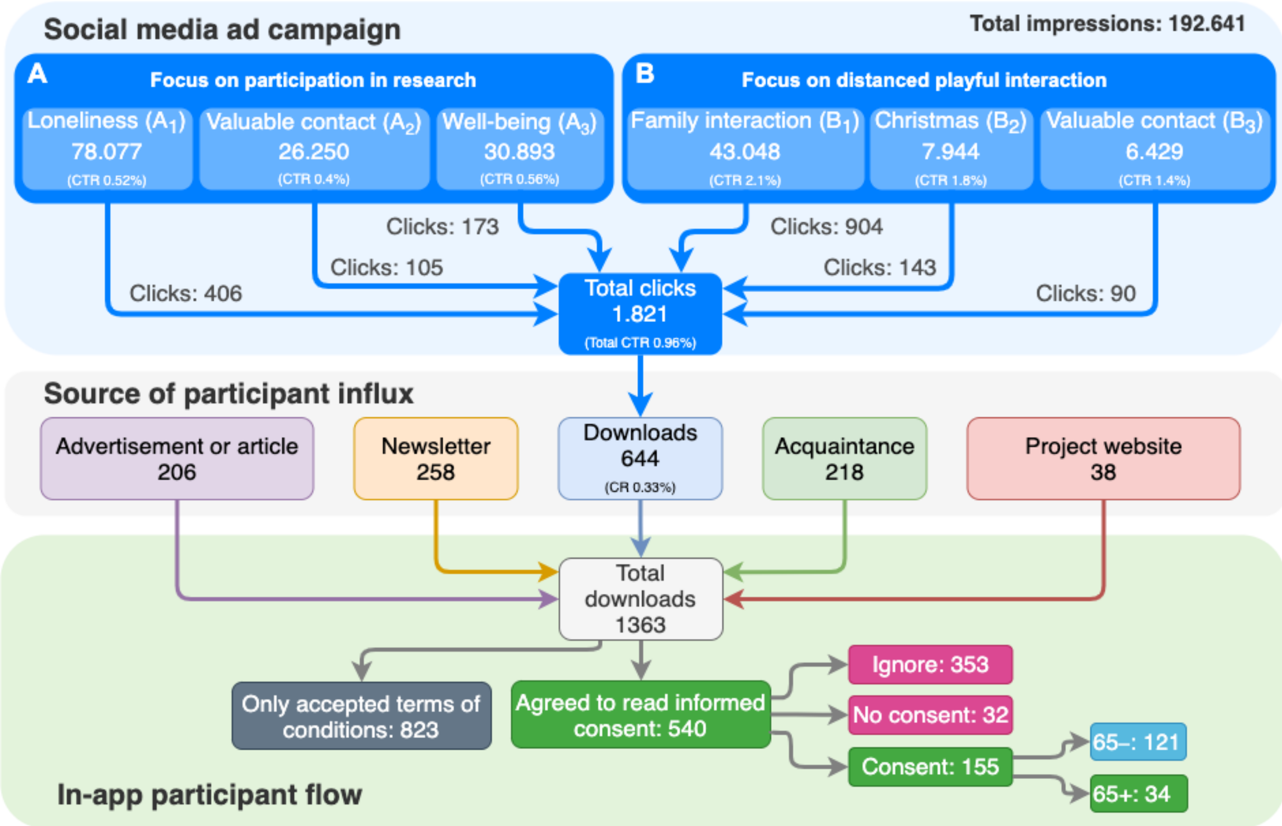
Among the 155 participants who provided informed consent, the average age for all participants was 48 (SD 16) years. The "65+" group had an average age of 70 (SD 5) years, while the "65–" group had an average age of 42 (SD 12) years. Both groups exhibited characteristics of being predominantly healthy, highly educated, married, female, living independently with others, and having children (Multimedia Appendix 2). In total, 57 out of 126 (45.2%) participants who completed the DJG questionnaire at baseline reported at least moderate levels of loneliness. The subgroup of 13 out of 27 (48.1%) participants aged 65 and older, experienced moderate loneliness, while 8 out of those 27 (30%) reported severe loneliness. Twenty-five participants gave consent to be contacted by the researchers, of whom 12 (48%; female: n=12, 83%) consented to be interviewed.

Participant Recruitment

Overview

Figure 1 depicts a higher CTR for focus (P<.001) on distanced playful interaction (CTR=1.98%) than focus *A* on research participation (CTR=0.51%). However, the reach of focus *A* was greater (70.2% of total impressions). Focus *B* generated more clicks, with 49.64% of the total number of clicks from the campaign emphasizing family interaction (B_1: CTR=2.10%, number of impressions=22.35%). The total CR of the social media campaign was 0.33%.

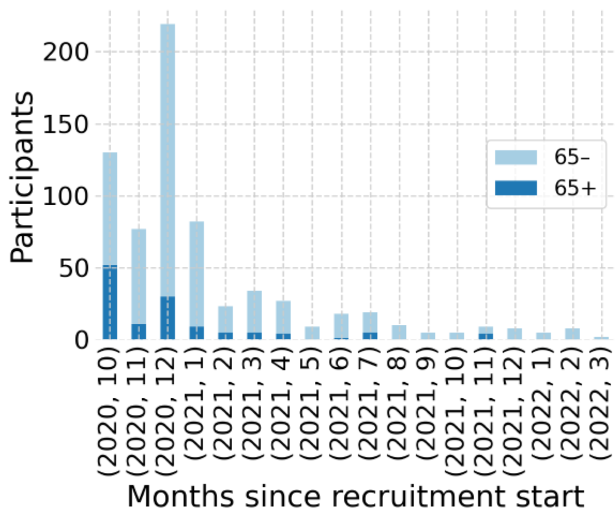
Figure 1. The flow of potential participants from ad exposure to informed consent. On the top level, the number of impressions is shown with the number of clicks and CTR per ad focus and emphasis. The middle level depicts the origin of how participants found the app. The bottom level illustrates in-app participant flow through different consent stages, ending with the number of participants 65 years or older (65+) and participants younger than 65 (65–). CTR: click-through rate.



Of the 1363 downloads, 823 participants only agreed to the mandatory terms and conditions, and 540 participants also agreed to receive research participation information, where the chatbot asked for informed consent. Of these 540 participants, 353 (65.3%) ignored the chatbot, 32 (5.9%) refused, and 155 (28.7%) gave informed consent. Among the 155 participants, 121 (78.1) were 65–, while 34 (21.9) were 65+. The total CR from advertisement exposure to research participation was 0.080% (ie, number of consent/impressions=155/192.641). As channels other than social media were also used, this total CR is an upper bound.

Regarding timing, Figure 2 shows an increase in participants at the app's launch due to initial recruitment efforts. A participant inflow peak follows due to the recruitment campaign between December 18, 2020, and January 4, 2021, followed by a decreased growth, stagnating at around 10 new participants per month. This stagnation indicates the importance of active and continuous recruitment efforts.

Figure 2. Participant influx over time per age group since the start of recruitment.



Feedback Through Qualitative Interviews

Some interviewees indicated that they did not invite someone else because the invitation process was unclear. Furthermore, some indicated that the app was not enjoyable enough to invite someone. One of the participants said:

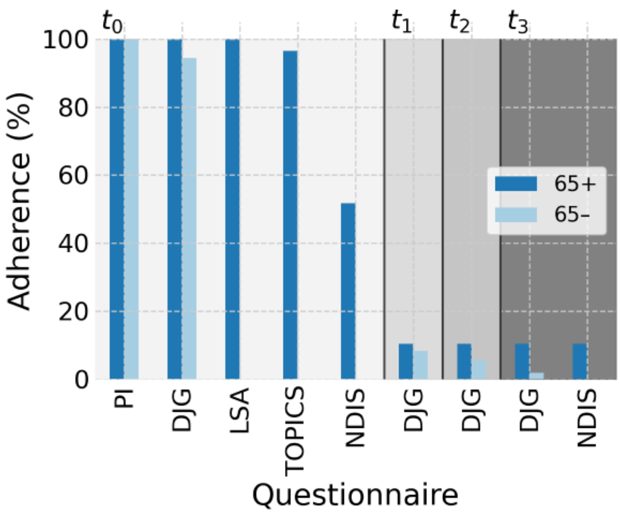
> *It was a barrier for me that I was going to involve others in something that annoyed myself.* [Participant, female, 78]

Data Collection Procedures and Intervention Acceptability

Overview

Questionnaire adherence was relatively steady for PI (N=29, N=109), DJG, and the Life Space Assessment questionnaires at baseline. However, there was a drop from 28 to 15 participants (a 46% drop) who completed the NDIS questionnaire after completion of the Older Persons and Informal Caregivers Survey questionnaire (Figure 3). During the following months, questionnaire completion rates were further reduced to 3 participants (10% relative to baseline), after which the 65+ group's completion rate remained stable while the 65– group continued to decline.

Figure 3. Questionnaire adherence compared to baseline (t0), with follow-up questionnaires each consecutive month. PI: Personal Information Questionnaire; DJG: De Jong-Gierveld Loneliness Scale; LSA: Life Space Assessment; TOPICS: The Older Persons and Informal Caregivers Survey; NDIS: Network Domain Identification and Significance.



Feedback Through Qualitative Interviews

Most interviewees expressed that the chatbot presented information pleasantly and explained the study goal well. However, to some, the chatbot felt slightly artificial, childish, or communicated too quickly. In addition, for some questions, the goal was judged unclear, so interviewees did not feel motivated to answer these questions, as 1 participant illustrated:

> *I did not exactly understand what it was about. So was that questionnaire, with all those contacts, to see if I have contacts? Or to see if I have many contacts? Or was it about finding people with whom I wanted to play a game? That was not clear.* [Participant, male, 77]

Interviewees also indicated that the questionnaires contained too many questions, making the average questionnaire duration unpleasant. One of the participants indicated:

> *I was filling out questionnaires all the time, and I didn't like that.* [Participant, male, 77]

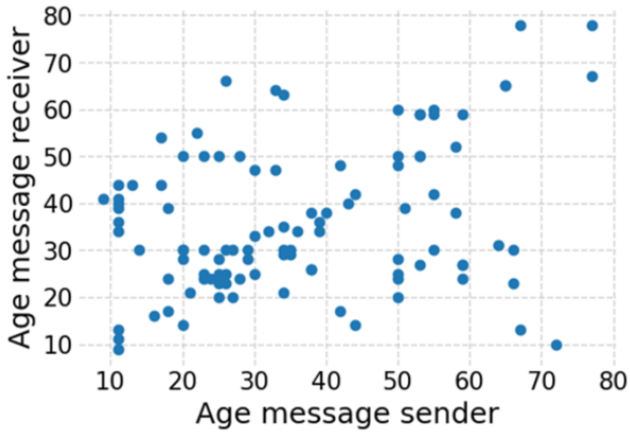
When asked how often interviewees were willing to answer questions, they indicated that monthly would be fine, provided it was not too long. Additionally, the NDIS required participants to disclose information about others, which many interviewees did not appreciate.

Participant Gameplay

Overview

Out of the initial 554 participants, 91 (16.4%) remained active after the first week, and 32 out of the 554 (5.8%) participants had more than 90 days of activity. Furthermore, assessing design choices toward intergenerational play, we found participants tended to play with players in their age stratum (*r*=0.31; Figure 4 and Multimedia Appendix 6).

Figure 4. Age of message sender and receiver. Each dot represents a message from the sender (x-axis) to the receiver (y-axis), based on their respective age.



Feedback Through Qualitative Interviews

Interviewees mentioned that the games were amusing, intuitive, and clearly explained. The games were often considered somewhat slow, old-fashioned, and childish in terms of content and appearance. Some indicated that the games should be more challenging and usually stopped playing after a few times. One of the participants mentioned:

> *Yes, I find it a bit, simple. They are party games, and there is little challenge in it.* [Participant, female, 66]

The number of games was considered enough by some and too low by others. Furthermore, interviewees mentioned not seeing the added benefit of the games in this app over established digital games. Interviewees mentioned that the games are most suitable for playing with children rather than with other adults. However, the interviewees who invited someone else generally invited a good friend or partner of the same generation.

Discussion

Principal Findings

This study investigated the recruitment and inclusion process of a serious game app to reduce loneliness in the older population. Due to the high dropout during the recruitment and onboarding process, substantial overshooting of the intended sample size was required. Of the 193,361 potential participants reached through social media, plus an unknown number through other channels, only 0.08% of participants provided informed consent, indicating significant challenges in recruitment. The A/B testing revealed that the campaign focusing on distanced playful interaction had a significantly higher CTR (1.98%) than the campaign focusing on research participation (CTR=0.51%). In-app activity analysis indicated that 16.4% of participants (n=91) remained active after the first week, but only 5.8% (n=32) stayed active for over 90 days. Interviews highlighted barriers such as excessive chatbot questions and a mismatch between the app's design and the target group's preferences. These findings underscore the difficulties in recruitment and retention.

Even though these low participation rates are considered typical in digital epidemiological research [50,51], especially in studies where enrollment is completely web-based [52], evidence for higher participation rates among older adults (though inconclusive) increased expectations [51]. Due to the nature and goal of our app, it is also possible that the stigma on loneliness [15] played a role in the low recruitment rate. Furthermore, the study's timing during the COVID-19 quarantining period made in-person recruitment strategies (eg, workshops and talks) more challenging, if not impossible.

Most growth came from social media, recruiting more than 200 people in 1 month through Facebook, suggesting participants can be reached. However, few participants completed the entire study. Additionally, when aiming to reach new participants through existing ones, the game did not result in players inviting others once they logged into the app. To that end, improvements to increase game satisfaction must be implemented. This mouth-to-mouth recruitment is considered powerful and should be prioritized [53]. One of the possibilities could be introducing a feature to recommend the game to a Facebook friend and receive in-game rewards. Another way to improve recruitment is to optimize organic user acquisition by, for example, increasing visibility at the top of distributor channel lists like the Apple App Store and Google Play Store, updating metadata often and using metadata keywords based on seasonal contexts [53-55].

After the first week post download, 16.4% of participants remained active; 5.8% remained active after the first 90 days. The questionnaire retention rate remained around 10% compared to the baseline. These retention rates comply with gaming industry standards where a 7-day retention rate of 8.6% and 30-day retention rate of 3.5% in European countries are regular among highly rated gaming apps [56]. Internet-based interventions also experience low retention rates compared to traditional interventions, especially in older populations [57-59]. However, intervention research attrition usually needs to be much lower than that of the gaming industry; attrition of 45% is already described as high [58-61]. Furthermore, player types and participation reasons play a role in retention [62], as differences could exist between players joining for gameplay versus those joining to participate in research. This mismatch between gaming and research standards might imply that initial sample sizes must be much higher than anticipated.

Data collection procedures (ie, backend data collection and chatbot) were considered pleasurable and straightforward. However, language use needs to be adapted per age category as older participants found the chatbot speaking too childlike. The chatbot's tone is essential as negative emotions regarding the chatbot might affect interaction willingness [63], possibly resulting in communication breakdown and increasing the number of missing values [64]. Furthermore, the questionnaires were considered too long and complicated. However, as the attrition rates after 1 month of play were similar between older adults and the younger group, it seems that questionnaire duration is not the only limiting factor, as the younger group did not need to answer all questionnaires. Additionally, even though interviewees preferred answering questionnaires in the app or on the computer, research shows that most older adults prefer answering questionnaires on paper or, if digitally, on the computer [65]. Therefore, our method of administering questionnaires could have been a barrier.

The games were designed to facilitate inter-generational contact, and participants confirmed they were most suited for children and older adults playing together. However, we found that most people played within their age stratum (ie, good friends and partners), corresponding with the literature suggesting that people of different ages do not uniformly intermingle [66]. This age segregation is not only a matter of preferences [66-69], but also a matter of institutional, spatial, and cultural segregation based on age [67,70-72]. Indicating that the design choices toward intergenerational gameplay did not have their intended effect and possibly even had an adverse impact as older users felt the app was too childish. However, the app is possibly only perceived as "childish" as participants did not interact with it within the context of its intergenerational intention.

Strengths and Limitations

The first strength of this study is the use of A/B testing as it helped understand recruitment through social media by providing insights into the discrepancy between the extensive reach needed and app downloads realized. Furthermore, it allowed for adjusting recruitment strategies and optimizing recruitment. A second strength is that we provide a detailed qualitative and quantitative evaluation of an innovation built with stakeholders (ie, older persons and game innovation companies), allowing for iterative analysis and improvement in a controlled and verifiable manner. A third strength regards the data collection during the COVID-19 pandemic. Loneliness has increased during COVID-19 [73,74] and many people, especially older adults, had less in-person social contact [75]. Therefore, the need for digital inclusion of older adults increased [76,77]. Furthermore, research shows that older adults use digital technology to improve social connectedness [78,79] and change how they use and adopt new technology during the COVID-19 pandemic [79]. The PlayingTogether app has the potential to fill the need for digital inclusion as it aims to make digital communication easy and accessible, possibly positively influencing some players to engage more with the game.

A first limitation is the timing of data collection during the COVID-19 pandemic as it made in-person recruitment strategies more difficult and therefore reduced inclusion numbers and lessons learned about the effectiveness of in-person recruitment strategies (eg, workshops and presentations). Consequently, recruitment shifted toward digital strategies. Though this made calculating the advertisement reach possible, it possibly caused the substantial filtering of 99.02% which is still a lower estimate as reach increases when adding unknown contributions through different channels. A second limitation is the representativeness of the target group in the in-game sample. Participants were few (ie, N=155), relatively young, highly educated, and not lonely, so the participant pool did not reflect the target group well. By campaigning toward a broad audience, we believed younger players would invite older potential participants; as lonely, more senior adults are hard to reach [80]. Though we successfully recruited a younger target group, this indirect recruitment did not occur, highlighting the difficulty of reaching a diverse group which hampers the game design process and assessment as the target group is underrepresented. A third limitation is that the app was in iterations of active development during the study, including an update on UI. This is also the case in most other eHealth innovations, as the iterations of innovation cannot wait until the end of a (slow) trial evaluation with long-term follow-up. However, making direct comparisons between players became more challenging with several app versions. Nevertheless, the interviewees' experiences did not differ between versions, indicating that the underlying problems were more profound than those covered by the updates. Finally, our intervention was designed too broad, with the intention to attract both older adults and their grandchildren. We tested game mechanics with older adults and grandchildren, but the intersection of games and questionnaires was not tested. Furthermore, the new UI, although it received the most votes in a digital campaign, was not rigorously tested by older adults and the younger generations. Therefore, the app might have felt "childish" for older adults, and too simple for younger generations, which made the app unsuccessful in connecting the different generations. This might have been overcome by more rigorous pilots and repeated tests within this intended context.

Future Directions

Based on the data and insights gained in this study, we deem the following matters important to address before further (large-scale) evaluation or implementation of social games in alleviating loneliness in older adults. First, game experiences must provide clear guidance to start and continue gameplay. One option could be to introduce volunteers scouted to keep communication energetic. They could catalyze communication and "break the ice" while monitoring participant activity so necessary changes can promptly be implemented. Second, the intervention needs a sharply defined target group that thoroughly tests the app and the intervention procedures. Our approach of using a mixed target group, comprising both older and younger generations, posed challenges in effectively engaging either demographic. Third, substantial initial recruitment investments and continuous advertisement strategies are essential for long-lasting digital effectiveness trials. Current efforts are insufficient for scaling up, as shown by a 99.92% drop from exposure to download and a 90% dropout rate after 1 month.

In-person recruitment could enhance engagement and reduce dropout rates.

There is increasing literature on digital gaming interventions and loneliness [81] and web-based interventions containing a gaming feature and loneliness [82]. However, we believe that further large-scale evaluation only becomes viable once these concerns are addressed. This study adds insights into the gap between the reach of potential participants and the actual recruitment outcome. Furthermore, we have shown how to design, develop, recruit for, and improve games for older adults and where these aspects might need to be improved for future endeavors.

Conclusions

We describe the development process and participant funnel from advertisement to app usage to provide context and guidance for future work. These stages often remain unreported even when crucial for acceptance and, thus, effectiveness. As such, this study underlines the difficulty of recruiting and retaining older adults in a social gaming intervention focused on loneliness. We showed that combining the target group with a hybrid solution to attract different generations leads to difficulty in providing a user experience where all users understand the app's intent and feel appropriately addressed. Furthermore, we have shown the discrepancy between advertisement reach and the number of included participants. This filtering process shows that casting a wide net does not necessarily result in high participation rates, indicating that expectations and recruitment strategies should be realistically assessed when initiating such interventions. More focused small-scale, in-person recruitment strategies might therefore be more effective in increasing participation and decreasing attrition.

The datasets generated and analyzed during this study are not publicly available due to privacy restrictions in accordance with the study sponsor but are available from the corresponding author upon reasonable request.

Authors' Contributions

BDLC, JHMJ, GMEEP, RC, RT, MD, and MGMOR conceptualized the trial. JHMJ, BDLC, and EJMH collected and analyzed the data. BC wrote the manuscript, to which all authors gave critical feedback. All authors approved the final draft of the manuscript.

Conflicts of Interest

RT and MD work with Games for Health, which was both a research partner and a commercial partner. Research-wise, they performed design research to explore and validate how to design for social interaction and quality contact to reduce loneliness. Commercial-wise, they investigated if and how a feasible business model could be created for this scope. This dual role was integral to the study's development and implementation, and it is disclosed to maintain transparency and integrity in reporting the research findings.

Multimedia Appendix 1
Sample size calculation.
[DOCX File , 28 KB - games_v12i1e52640_app1.docx]

Multimedia Appendix 2
Participant demographics.
[DOCX File , 299 KB - games_v12i1e52640_app2.docx]

Multimedia Appendix 3
Stages in app design process. An overview of the design process's different stages (project specification, development, and testing). We first specified a problem statement, followed by identifying the target group. Then a minimal viable product prototype was made and released, and a series of tests and feedback rounds with participants followed.
[PNG File , 454 KB - games_v12i1e52640_app3.png]

Multimedia Appendix 4
User interface of the app. Panels A, B, and C show the first user interface in gray tones. Panels D, E, and F show the user interface based on what users found most appealing through a feedback campaign. Panels A and D show the home screen with the

participants' chatgroups. Panels B and E depict the game repository screen with a short explanation of each game and a carousel through which the user can swipe for more games. Panels C and F depict the appearance of a chatgroup, in this case, that of the chatbot administering questionnaires.
[PNG File , 853 KB - games_v12i1e52640_app4.png]

Multimedia Appendix 5
Interview guide.
[DOCX File , 16 KB - games_v12i1e52640_app5.docx]

Multimedia Appendix 6
In-depth analysis of participant gameplay.
[DOCX File , 260 KB - games_v12i1e52640_app6.docx]

Abstract

Background: This study explores gamification in the design of virtual patients (VPs) to enhance the training of Swedish military medics in trauma care. The challenges related to prehospital trauma care faced on the battlefield require tailored educational tools that support military medics' education and training.

Objective: The aim of the study is to investigate how to design VPs with game elements for Swedish military medics to support learning in military trauma care. By understanding the reasoning and perceptions of military medics when interacting with VPs, this study aims to provide insights and recommendations for designing VPs with game elements that are specifically tailored to their needs.

Methods: The study involved 14 Swedish military medics of the Home Guard–National Security Forces participating in a tactical combat care course. Participants interacted with 3 different VP cases designed to simulate military trauma scenarios. Data were collected through think-aloud sessions and semistructured interviews. The data were analyzed using interaction analysis, structured by the unawareness, problem identification, explanation, and alternative strategies or solutions (uPEA) framework, and reflexive thematic analysis to explore participants' reasoning processes and perceptions and identify possible game elements to inform the VP design.

Results: Mapping the military medics' reasoning to the uPEA framework revealed that study participants became more creative after making a mistake followed by feedback and after receiving a prompt to make a new decision. The thematic analysis revealed 6 themes: *motivation, "keep on trying"*; *agency in interaction with VPs*; *realistic tactical experience*; *confidence, "I know that the knowledge I have works"*; *social influence on motivation*; and *personalized learning*. Participants suggested that game elements such as scoring; badges; virtual goods; progress bars; performance tables; content unlocking; hints; challenge; control; imposed choice; narrative; avatars; sensation; randomness; difficulty adapting; competition; leaderboards; social pressure; progression; and renovation can promote engagement, motivation, and support confidence in decision-making.

Conclusions: Gamification in the design of VPs represents a promising approach to military medical training, offering a platform for medics to practice medical and tactical decision-making in a risk-free environment. The insights gained by the study may encourage designing VPs with game elements, as well as including possibly wrong decisions, their consequences, and relevant feedback, that may support military medics' reflections and decision-making.

Introduction

Background

Virtual patients (VPs) have the potential to support the training of competencies required to operate in military settings [1]. VPs are interactive, computer-based simulations of real-life clinical scenarios designed to support health care and medical training, education, or assessment [2]. Gamification, the use of game elements in nongaming contexts [3], is gaining interest in education. Examples of game elements include scoring, avatars, badges, storytelling, and adaptive difficulty levels [4,5]. The incorporation of these elements in education has shown promise in enhancing engagement, motivation, and improving learning outcomes, particularly when these elements promote learning behaviors and attitudes [6]. Gamification appears to be at least as effective as traditional educational methods and often more effective for improving knowledge, skills, and satisfaction in health professions education [7].

Game elements can be combined with other educational methods or technologies. For instance, when gamification is combined with extended reality technologies, such as virtual reality and augmented reality, it offers a powerful approach to modern education by creating immersive and interactive learning environments that make learning more engaging and motivating. The integration of gamification with extended reality can thus transform traditional pedagogical methods, leading to more meaningful and student-centered learning [8]. Applying game elements in the design of VPs for military trauma training has the potential to provide learners with active learning opportunities to prepare for providing medical services under austere conditions [9].

In Sweden, the Home Guard–National Security Forces [10] is a military reserve force of the Swedish Armed Forces that consists mainly of local rapid response units. In addition to personnel who have completed their national service or basic military training, the Home Guard includes a large proportion of various specialists, including military medics.

The Swedish model of military prehospital emergency care has 3 levels, where the first level expects that a wounded soldier on the battlefield shall receive first aid from another soldier or a military medic as soon as possible [11]. The education and training to become a military medic requires essential skills vital to wartime scenarios, where medics are tasked with providing initial basic life support and assisting military nurses or physicians.

Prehospital trauma care on the battlefield differs significantly from that practiced in the civilian sector, particularly in terms of the types and severity of injuries encountered. Military medical personnel face additional challenges in providing care to their wounded teammates under tactical conditions. Unlike natural disasters or civilian incidents such as traffic accidents, where the immediate danger typically subsides and care can be administered in relative safety; battlefield medics might need to deliver care while under hostile fire; frequently dealing with multiple casualties; limited resources; and harsh environmental conditions such as rain, cold, and darkness.

Hemorrhage is the leading cause of preventable death in both military and civilian trauma, making the outcomes of care provided in tactical settings critically important. As gun violence rises in some European countries, injuries more commonly associated with the battlefield, such as gunshot and blast wounds, are increasingly seen in civilian life, representing a growing public health concern [12]. However, the nature of gunshot wounds caused by military ammunition often differs from those typically encountered in civilian settings, primarily due to the higher velocity and a greater kinetic energy of military rounds, which result in more extensive tissue damage [13].

Treatment guidelines developed for the civilian setting do not necessarily translate well to the battlefield. Sometimes, solutions need to be improvised [14]. Courses such as the Tactical Combat Casualty Care (TCCC) initiative are a set of evidence-based, prehospital trauma care guidelines customized for use on the battlefield. These guidelines may be used by battlefield medics, corpsmen, and pararescuemen to acquire trauma management strategies that integrate medical principles with effective small-unit tactics. The curriculum for this training outlines specific objectives, emphasizing the military medics' need to comprehend the effects of trauma on the human body, administer subsequent treatment, and deliver initial prehospital care. Following the training, military medics are expected to be able to make critical decisions on the battlefield, combining medical care with tactical decision-making [15].

While military medics across different armed forces may have varying duties and organizational structures, their exposure to handling trauma patients is limited. This challenge is further compounded by a lack of research on the learning processes and educational strategies tailored to support the training of military medics [14].

The educational value of VPs can be understood through the experiential learning theory [16], which emphasizes the importance of action and reflection in a safe environment that can tolerate errors [17,18]. VPs may offer a potential solution in preparing military medics by providing a controlled environment where they can practice their skills, make critical decisions, and learn from their mistakes without real-world consequences, ensuring they are better prepared for situations they may face in the field. The risk-free environment offered by VPs has been previously emphasized as their key characteristic in a systematic review of VP descriptions [19]. Through VP simulations, military medics can experience a breadth of scenarios, from the common to the rare and complex, ensuring they are better prepared for situations they may face in the field.

Despite the potential of VP simulations to enhance military medical training, there is a lack of studies focused on incorporating gamification into the design of VPs for military medics. This gap highlights the need to explore how to effectively integrate game elements into VP design to meet the unique demands and learning objectives of military trauma education while increasing engagement.

Aim

The aim of the study is to investigate how to design VPs with game elements for Swedish military medics to support learning in military trauma care. By understanding the reasoning and perceptions of military medics when interacting with VPs, this study aims to provide insights and recommendations for designing VPs with game elements that are specifically tailored to their needs. The study has two research questions:

1. How do Swedish military medics reason when interacting with the VPs?
2. What are the military medics' perceptions of VPs?

Methods

Study Setting and Participants

A course took place from October 21 to 28, 2023, in a military training area located in Väddö, Sweden, as part of the TCCC training for the Swedish Home Guard. The training aimed to teach Home Guard soldiers basic concepts of TCCC (as part of the TCCC Combat Lifesavers course [TCCC-CLS]) based on the published guidelines [20,21]. This was the first time the TCCC-CLS course took place for the Swedish Home Guard, using the US-standardized TCCC training guidelines and material. The course was attended by 30 participants; 14 (47%) participants were recruited to participate in the study with purposeful sampling. Participants with different professional backgrounds were included to achieve variation in the data [22]. In particular, 11 (37%) participants were soldiers of the Home Guard in Sweden with mixed backgrounds and 3 (10%) participants were course instructors.

Data Collection

The data collection took place on October 27, 2023, in Väddö, Sweden. A think-aloud method was used while each participant interacted individually with the 3 VP cases, to answer the first research question. Directly after the think-aloud sessions, each participant discussed the cases in semistructured interviews. Two authors (NS and KK) conducted think-aloud and semistructured interviews with the 14 participants.

Development of the VPs

Three VP cases were developed using the Open Labyrinth open-source system [23]. The content of the VP cases was cocreated with the support of the Home Guard of Sweden in collaboration with the instructors in combat casualty care. The content was designed first in a PowerPoint (Microsoft Corporation) format. To inform the decision points and the content of the VPs, recorded sessions took place with Home Guard members with mixed backgrounds, specifically educators with backgrounds in medicine, nursing, ambulance nursing, combat casualty care, and TCCC-CLS. The 3 cases addressed trauma management caused by gunshot and blast injuries. The cases included key medical and tactical decisions. The medical decisions concerned the use of the <c>ABCDE protocol [21] where the "c" relates to stopping the catastrophic bleeding. Because the medics learn the <c>ABCDE protocol and the military alternative "MARCH" (massive hemorrhage, airway, respirations, circulation, head injury, and hypothermia), the VPs were developed without explicitly referring to the letters of the acronyms, as these can easily be memorized without full understanding of each letter's meaning. For instance, instead of phrasing a decision alternative as "select A," the VPs listed the decision as "select to check the airway."

Design Principles

The VP cases were developed using design principles identified in the literature and the authors' own experience. Photos from exercises and educational materials of the Home Guard in Sweden, along with images generated using OpenAI's DALL-E artificial intelligence system [24], were used. A key design principle was to "emphasize a feeling of presence by keeping the patient visible." To maximize the sense of presence and not let the interaction become an overly theoretical exercise, the trauma patient was kept visible during every decision the learner made as if the patient was in front of the learner.

We aimed to emphasize the participants' control and the feeling of being in charge rather than a spectator. The interaction with the VP focused on the user's next step, enhancing emotional involvement and placing the responsibility for patient care on the learners, requiring them to act quickly and manage the visible trauma. VPs were designed to prompt learners to make decisions as if they were a military medic using first-person language, for example, "I decide to approach the injured soldier." This approach aimed to immerse the learner in the role and responsibility of a military medic. Incorrect medical decisions, such as failing to prioritize stopping catastrophic bleeding, would result in patients dying from hemorrhage. Suboptimal tactical decisions endangered the user's character, potentially resulting in injury or death.

The VPs were designed as linear scenarios [25]; if a wrong decision was made, the learner was asked to try again. By clicking "try again," the learner would be navigated back to the previous key decision node, either medical or tactical, and asked to try again. There was one possible pathway for all VPs, leading to one final case outcome.

A 2-fold scoring system was developed to gamify the VPs, awarding or deducting 10 points for every correct or incorrect medical or tactical decision. Figures S1-S3 in Multimedia Appendix 1 visualize the 3 VPs, with TKD representing tactical key decisions and MKD representing medical key decisions. Table S1 in Multimedia Appendix 1 provides an example of the key decision content of VP1.

The 3 cases were designed with varying levels of difficulty. The first case was the simplest medically, while the third was the most complex. However, the first case involved massive bleeding, making its simplicity not immediately apparent. The scenario provided hints about suspicious objects in the remote area, requiring the user to prioritize tactical safety before assisting the patient. The second case was somewhat more challenging, involving facial bleeding that needed to be controlled in a remote area with an active threat, requiring the medic to approach the patient carefully while taking cover behind stones. In the final case, the patient initially appeared to be in good condition—smiling but slightly confused—yet eventually died due to brain bleeding. In all 3 scenarios, the learner assumed the role of a military medic, tasked with aiding an injured soldier. Each case began with a critical tactical decision, where a wrong choice led to the medic's death, either from stepping on a cluster bomb or coming under enemy fire. Prioritizing safety was essential in all cases, even though it was not always immediately obvious.

Piloting the VP Cases

Two researchers, associated with Karolinska Institutet, both with civilian nursing backgrounds and specific experience with medical education, gamification, and civilian emergency and medical education, respectively, were contacted for piloting the VP cases. The 2 researchers conducted the think-aloud sessions and participated in the semistructured interviews. At the last step, they provided feedback as experts, using experience from gamification, emergency medicine, and medical education. After receiving feedback and improving the VPs, the content was validated with the Home Guard combat casualty care course leader.

Think-Aloud

Think-aloud is a technique where the participant is asked to talk-aloud while solving a problem. Participants are encouraged to verbalize their thoughts as they work through the task. Think-aloud is a method that, in principle, does not lead to much disturbance of the thought process [26]. In our study, participants were prompted to elaborate on their decision-making while playing the cases.

Interaction Analysis

Interaction analysis was used to analyze the video-recorded think-aloud sessions. Interaction analysis brings focus on the important moments in the learning activity, such as the interaction of military medics with the VPs and their reasoning while making tactical and medical key decisions. This method eliminates the researchers' bias by grounding assertions on the video-recorded sessions, making them verifiable [27].

The primary objective was to identify recurring patterns of user actions while interacting individually with the VPs. First, NS and KK reviewed the video-recorded think-aloud sessions. We observed that the participants' comments increased considerably whenever they made a mistake. Therefore, we decided to map the data from the think-aloud sessions to the unawareness, problem identification, explanation and alternative strategies or solutions (uPEA) framework to analyze how they reasoned in relation to becoming aware of problems and dealing with those, particularly after encountering consequences of wrong decisions. Our analysis followed a deductive-inductive approach to qualitative data analysis [28]. The uPEA framework has been previously used to analyze participants' reflections during post-simulation debriefings [29].

Semistructured Interviews

Semistructured interviews were conducted to understand how the military medics perceive the VPs and how game elements can inform the VP design. An interview guide with questions was developed by the first author, reviewed by 2 additional authors (AAK and KK), and the questions can be found in Table S2 in Multimedia Appendix 1.

Thematic Analysis

To analyze the semistructured interviews and identify patterns and themes in the dataset, a reflexive thematic analysis was used following the 6-step approach suggested by Braun and Clarke [30]. The thematic analysis was conducted by the first author (NS) and discussed with AAK and KK in a collaborative and reflexive manner, aiming to achieve richer interpretations of meaning. First, the transcripts were generated using the automatic transcription tool Word (Microsoft Corporation) "transcribe." NS actively revisited all interviews and recordings and went through the automatically generated transcripts to edit them and generate preliminary notes; then codes were created to encapsulate the meaning of the text. In an iterative manner, themes were actively developed and revisited to form the results and emphasize themes relevant to the research questions.

An additional round of coding was dedicated to associating the participants' statements to game elements. Using a framework by Toda et al [4] and Maheu-Cadotte et al [5], which we previously used in our research, we performed this mapping organically following a deductive-inductive approach. We actively connected phrases from participants' discussions to game elements based on our experience in gamification.

Reflexivity

The reflexive thematic analysis as outlined by Braun and Clarke [30] is a widely recognized method for identifying, analyzing, and reporting patterns (themes) within data. Their approach emphasizes the importance of the researcher's reflexivity in the analysis process. NS has a background in health informatics and an interest in educational technologies, particular VPs, and gamification. This background has been informing the way that the interview data were interpreted. KK has a background in interaction design and is a senior researcher within the field of medical education, with a particular interest in technology-enhanced learning. AAK has a background in computer science and is experienced as a researcher in topics around technology-enhanced medical education and clinical reasoning.

Ethical Considerations

Ethics approval was sought from the Swedish Ethical Review Authority (diarienr 2016/1701-31), followed by an amendment in 2020 (diarienr 2020-01660). The Swedish Ethical Review Authority exempted the study from the requirement for ethics approval, as it did not involve handling sensitive personal data, as defined by the Swedish Ethical Review Act.

The video recordings were limited to capturing the laptop screens used, demonstrating participants navigating through the

VPs with synchronized voice audio tracks of the participants. No identifiable data about the observed participants were collected. Recordings began only after each participant received oral and written information about the study. Participation could be interrupted at any time without any consequences. All study participants signed a consent form.

Results

Overview

A total of 14 military medics participated in the think-aloud and interview sessions. All participants completed the 3 VP cases. The VP cases and the nodes visited by the participants are visualized in Figures S4-S6 in Multimedia Appendix 1. Most visited nodes are visualized with dark gray ranging to light gray and white for less-visited nodes and nodes not visited at all. The number within each node shows the number of clicks per node.

Swedish Military Medics' Reasoning When Interacting With the VPs

Overview

The uPEA categories were mapped to the participants' discussions around key decisions as follows: "unawareness" was used to refer to how participants were unaware of a problem that they would subsequently encounter and become aware of. The participants could, for example, comment on the background information, text, and images seemingly unaware of any pending danger or risks just before making a mistake. "Problem" was used to refer to reflections on how the participants realize that they made a suboptimal or incorrect decision. At this point, they discover that the consequences of their decision were not the desired ones. "Explanation" was used to categorize discussions and explanations of why the problem occurred, for instance, to justify a wrong decision made by the participant. The category "alternative strategies or solutions" was used to refer to alternative decisions made after recognizing the problem and considering actions that would avoid similar issues in the future. An overview of different kinds of reflections made by the participants during the different phases is presented in Figure 1.

An example of a participant's (participant 10) reasoning, mapped to the uPEA framework, is presented in Figure 2. The example outlines the participant's reasoning process, starting with his initial unawareness of the risks as he decides to proceed toward the injured patient without hesitation. As he moves forward and steps on a mine, he realizes that he had overlooked the danger, identifying this as the problem (P, which stands for problem identification). He then provides an explanation for his mistake, attributing it to the brevity of his military training (E, which stands for explanation). Finally, he elaborates on how he would act differently in a similar situation in the future (A, which stands for alternative strategies or solutions).

The interaction analysis and the uPEA mapping allowed us to generate the following categories that bring insights about how military medics reason while interacting with the VPs.

Figure 1. An overview of different kinds of reflections observed during the different phases of the unawareness, problem identification, explanation and alternative strategies or solutions framework. VP: virtual patient.

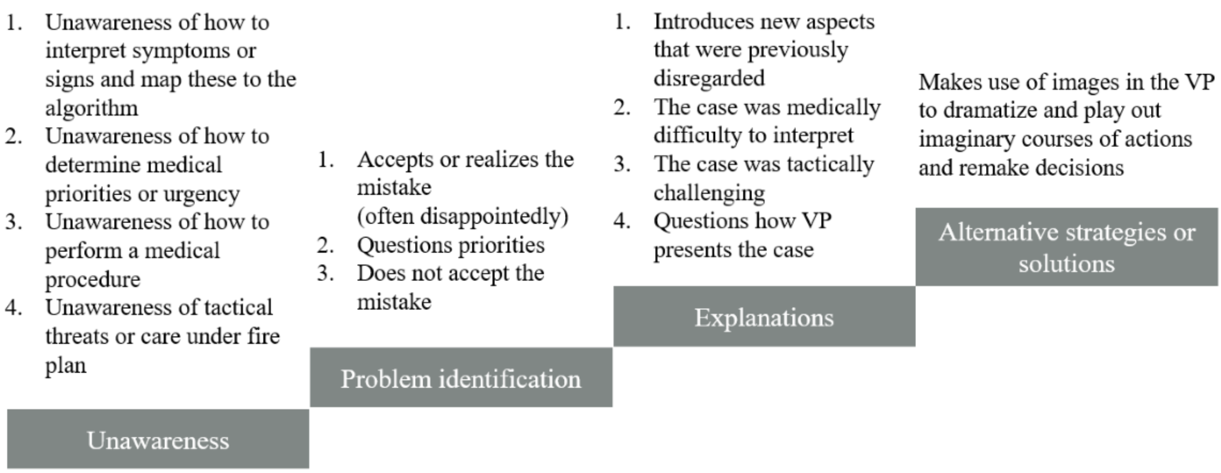

Figure 2. An example of a participant's reasoning mapped to the unawareness, problem identification, explanation and alternative strategies or solutions framework (participant 10).

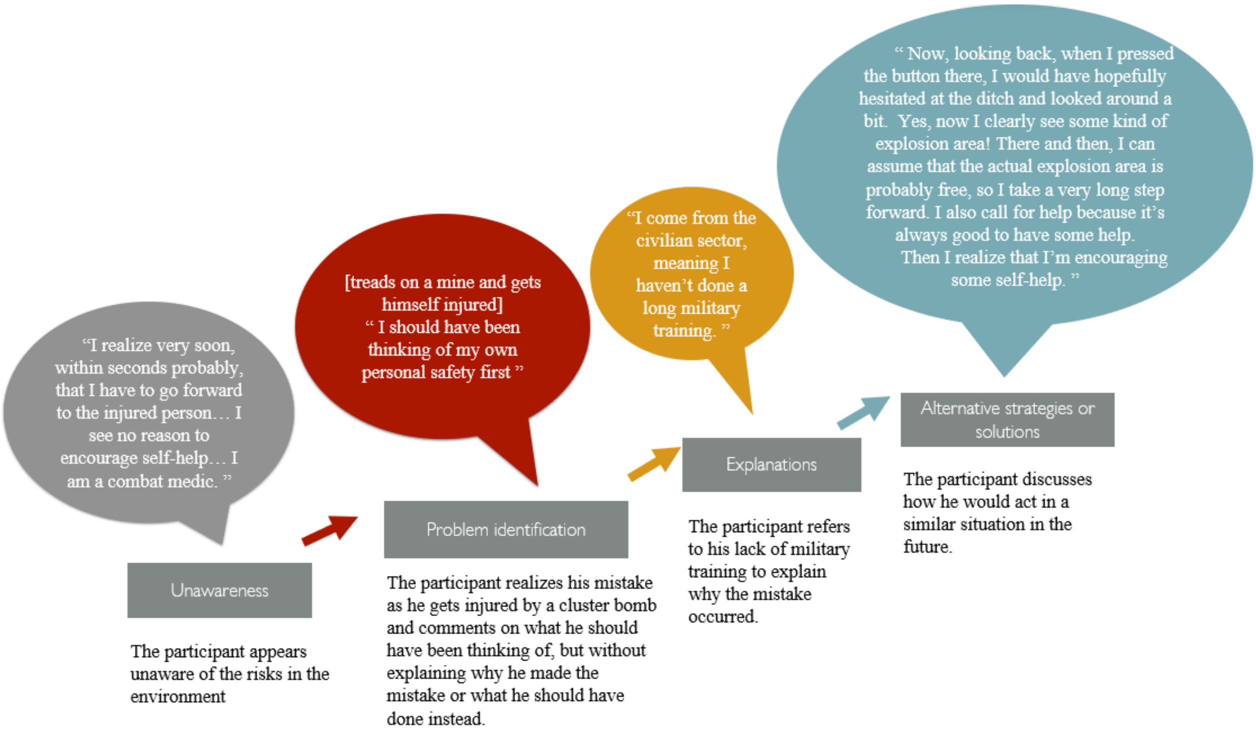

Unawareness

Overview

Participants were often unaware of factors that contributed to the error that they would later make. They seemed not to reflect on the aspects that they would later bring up as important in their explanations. For instance, participants would exclaim that they should hurry to the wounded patient without encouraging self-help because it was part of their role as a combat medic without mentioning the risks involved. Alternatively, looking at an image of a wounded patient concluded that the patient would probably not die, thus apparently unaware of the risk that the patient had latent fatal injuries. In subsequent sections, we have categorized different themes of unawareness.

Unawareness of How to Interpret Symptoms or Signs and Map These to the Algorithm

In the first VP case, the term "massive bleeding" was used, and all participants recognized the necessity to prioritize it and stop the bleeding. Thus, everyone made the correct medical decision in the first VP. However, in the second case, several military medics were confused when the term "pulsatile bleeding" was introduced instead of the usual term "catastrophic bleeding" and had difficulty mapping the <c>ABCDE algorithm to the case, even if there were hints of the necessity to prioritize to stop the bleeding. This implies that even if the participants have been trained to the protocol with clear examples of what step to prioritize, they had difficulties applying the same concept to a broader case without a clear hint referring to "catastrophic" bleeding:

> *There are many things to do, but I need to prioritize cleaning the mouth so that he can breathe. It would be good to stop the bleeding too...But it [the injury] is on the face and jaw...But there is pulsating bleeding in the injured area...It is not catastrophic bleeding. Then one could try...I am between these two [pointing at two options, to stop the bleeding vs to clean the mouth]. I will select this one thought [to clean the mouth].* [Participant 5]

Unawareness of How to Determine Medical Priorities or Urgency

In the second VP case, the patient with trauma on the face caused confusion because of the anatomical location, as the trauma was around the missing jaw. Many participants thought that they should try to free the airway and prioritize breathing instead of stopping the bleeding:

> *I will try to see whether there are things one can see [in the mouth] so that I can take them out. And then I will try to stop the bleeding, but this is after I check the airways, so this is the order I would follow...* [Participant 4]

In the third VP case, a picture of a smiling patient appears, who has internal brain bleeding. Although the case is considered medically challenging, several medics understood that there might be a head injury, even if the medical urgency was not always clear, which resulted in the patient's death:

> *I think he has a head injury. He is probably not going to die, and he doesn't seem to have anything wrong with his limbs...* [Participant 11]

Unawareness of How to Perform a Medical Procedure

While dealing with the second VP case, some participants thought that it was practically impossible to stop the bleeding around the mouth area. Therefore, they proceeded with other priorities. While the anatomical positioning of the injury might have influenced their decision-making, the practical perception of how to stop the bleeding and its feasibility was unclear to some of the participants:

> *If it is pulsatile bleeding, it is not easy to set something [means like a tourniquet] on the face. So, I will select to free the airways.* [Participant 8]

Unawareness of Tactical Threats or Care Under Fire Plan

Many medics were confused in making a decision between "directing the casualty to move to cover and apply self-aid" and "selecting to run to help the patient." Directing the casualty and encouraging self-aid is one of the priorities of the first phase of the care under fire or threat, according to the TCCC protocol. However, given the design of the VP, which presented a bleeding patient screaming for help, many medics rushed to help the bleeding patient, which resulted in stepping on a cluster bomb and injuring themselves:

> *...I am safely approaching the injured person on my knees. Securing my weapon, I realize very soon, within seconds, probably, that I have to go forward [to the injured person] because I see that he probably bleeds a lot. I see no reason to encourage self-help because he is actually an injured person, and I am a combat medic.* [Participant 10]

Problem Identification

Overview

The VPs provided feedback to the users after each correct or incorrect decision. Sometimes the feedback was just textual, but often the consequences of a decision were quite concrete, so that it was obvious to users that they had made a mistake. If a user was not careful enough and stepped on a mine, such a decision would result in an explosion injuring them, presented in an image. In this section, we describe the reactions and reflections of the participants when it became clear that they had made an incorrect decision. These varied between acceptance, acceptance with a large portion of disappointment, questioning the priorities that should be made, and not accepting the mistake.

Accepts or Realizes the Mistake (Often Disappointedly)

Some participants accepted the mistake after it became obvious to them, through experiencing the consequences or through the VP feedback. Often, realizing and accepting the mistake involved disappointment:

> *...So is it over now? [after stepping on a cluster-bomb, which resulted in an explosion].* [Participant 3]
>
> *…Oh, no! I should have been thinking of my own safety first.* [Participant 5]

Questions Priorities

Reactions to the wrong decision-making also included questioning the priorities presented in the VP. For example, questioning the priorities in the basic management plan for care under fire or threat, where instead of the tactical priority "return fire and take cover," the participants had to select "direct casualty to move to cover and apply self-aid if able or when tactically feasible, move or drag casualty to cover" because, in the case, there were no enemies presented:

> *So, isn't the first priority to kill the enemies?* [Participant 1]

Does Not Accept the Mistake

In some other cases, the participants did not accept the mistake after it became obvious to them:

> *This was wrong, ok. I need to read the text again. Aha, ok, it states that it is pulsatile bleeding. It is just that I read wrongly. Yes, I will stop the bleeding first. It is just that I read wrongly.* [Participant 2]

Explanations

Overview

After having made a mistake, the participants would often stop to reflect on why the mistake took place. Participants offered explanations to why they selected a suboptimal option, such as lack of tactical training, and they sometimes also seemed to rationalize their decisions and attribute mistakes to limitations of the VP scenarios or their interpretations. This process often involved participants justifying their actions by uncovering aspects they had not initially considered.

Introduces New Aspects That Were Previously Disregarded

> *There is no sign of threat in the picture; that's why I thought of running to help [the patient]. There can be more cluster-bombs on the way, and that's why I would follow the same pathway as him. But of course, there are risks on the way...* [Participant 3]

The Case Was Medically Difficult to Interpret

> *It was wrong, yes, but it is a bit difficult to stop the bleeding on the mouth area...That's how I thought [and skipped it]. When the patient looks like that [pointing at the picture], then I should clear the mouth because otherwise he will not have a free airway. But if it is catastrophic bleeding, then of course I will have to press [stop the bleeding] first...But the picture is limiting the understanding of how serious the catastrophic bleeding is.* [Participant 7]

The Case Was Tactically Challenging

> *I come from the civilian sector, meaning I haven't done a long military training.* [Participant 5]

Questions How the VP Presents the Case or Reality

VP limitations that were mentioned to justify wrong decision-making were the (1) picture limitations, (2) a limited number of listed alternatives to choose from, (3) a limited number of options to select at a time, and (4) limited sensory simulation (only sight is involved, and no other senses)

> *In a real situation, one receives more information. One has a smell, a taste; it is like déjà vu. I think I would perform better if I was there, and I had all these things in front of me, so I don't need to get all this information [from the VP text]. It would be a long text to give all these details, i.e. how much he is*

> *bleeding from the face...But one can't quantify that either, right?* [Participant 5]

Alternative Strategies or Solutions: Makes Use of Images in the VP to Dramatize and Play Out Imaginary Courses of Actions and Remake Decisions

At the last stage of the reasoning, some of the military medics shifted from justifying their wrong decision-making to reflecting and remaking correct decisions. Not all participants would reflect on alternative solutions and quickly just selected another VP option. However, others engaged in describing scenarios, dramatizing, and playing out imaginary courses of action that they could have chosen instead of making the error. Two examples of participants immersing themselves in the role of a military medic are presented in blockquotes later and in Figure 2. These 2 participants had previously made the wrong decision to quickly approach and help a wounded soldier, without sufficient caution, thereby becoming injured:

> *I see now that it seems to be in the picture an open territory and that it might be challenging to hide oneself. But there seem to be stones on the ground, and I can imagine that there must be somewhere a bigger stone that I can use to hide myself...If there was a lot of fire going on, I would have approached Sandstedt [the wounded soldier] carefully, ready to exchange fire. If there were enemies around, I would shoot them and prioritize that over Sandstedt, so that we avoid being two dead people.* [Participant 1]

Military Medics' Perceptions of VPs

Overview

The thematic analysis resulted in the following themes: *motivation, "keep on trying"*; *agency in interaction with VPs*; *realistic tactical experience*; *confidence, "I know that the knowledge I have works"*; *social influence on motivation*; and *personalized learning*. Within each theme, corresponding game elements were developed through the second round of coding and linked to the participants' discussions. These game elements were inspired by previous studies [4,5] and were further developed and defined based on the authors' experience. Table 1 presents a summary of the game elements mapped to the themes and defines them within the context of this study.

Table 1. Summary of defined game elements and how they map to the developed themes.

Game elements	Definitions	Themes
Scoring	Assigning points for correct actions or decisions and deducting points for incorrect ones to provide feedback and encourage improvement	1, 4, and 6
Badges	Visual symbols of achievement awarded for completing specific tasks or reaching milestones	1
Virtual goods	Digital items earned through performance that can be collected or used within the VP[a] environment	1
Progress bars	Visual indicators showing the learner's progress through tasks or learning objectives	1
Performance tables	Detailed overviews of the learner's performance across multiple tasks or criteria	1
Content unlocking	Access to new content or pathways based on the learner's performance or decisions	1
Hints	Clues provided to help learners find the correct answers without giving them away directly	1
Challenge	Elements designed to test the learner's abilities and maintain engagement	1
Avatars	Digital representations of the learners or patients within the VP environment	1 and 2
Control	The player's ability to influence the game environment and outcomes through their actions	2
Imposed choice	Providing learners with multiple decision options and requiring them to select a specific one to proceed, preventing further progress in the virtual patient scenario until the correct choice is made	2
Narrative	The structured sequence of events and choices that shape the learner's experience	2
Sensation	The use of sensory stimuli, such as visual and auditory cues, to enhance immersion	3
Randomness	Introducing unpredictable elements into the simulation to create a more realistic and challenging environment	3
Difficulty adaptation	Adjusting the level of difficulty based on the learner's performance	4 and 6
Competition	Encouraging learners to compete with each other, often through leaderboards or similar mechanisms	5
Leaderboards	Rankings that display top scores to motivate learners through competition	5
Social pressure	Influence from peers or the community that can motivate or demotivate learners	5
Renovation	Opportunities to retry decisions and improve outcomes based on feedback	6
Progression	Tracking and visualizing a learner's development and achievements over time	6

[a]VP: virtual patient.

Theme 1: Motivation, "Keep on Trying"

Motivation was a central theme in the discussion with the participants. While referring to the VPs, participants reflected on features and aspects that could enhance motivation during their interactions. Participants discussed scoring and its potential to increase motivation by encouraging continuous efforts to achieve higher scores. Participants also highlighted badges and virtual goods [5] as elements that could boost motivation and reward good performance. For instance, participants mentioned collecting stars or virtual items, such as virtual food, as incentives for performing well.

Visual progress bars [4] and performance tables [5] were suggested to visualize medical and tactical decision-making progress while interacting with the VPs. For instance, the participants suggested that virtual progress bars with color could depict correct, suboptimal, and wrong decision-making. In addition, participants suggested that branched VPs could unlock content [5] and allow them to interact through avatars [5] with different pathways depending on their decisions, enabling them to explore the consequences of their actions. Content unlocking refers to access to new content or pathways based on the learner's performance or decisions. This mechanism could motivate participants to perform actions correctly to unlock more content.

Overall, participants appreciated direct feedback after making a wrong decision. However, they suggested that feedback should provide hints [5] of the correct answer rather than giving it away directly to challenge [4] the participants and maintain their interest:

> *...Progress bars would be good to see where you are, for example, in your way. One can have one progress bar with yellow, green, and red for tactical decisions, and one can have another one yellow, green, and red for medical decisions.* [Participant 4]

> *...Say, for example, if you get a certain point, you would then be able to unlock something...You can unlock something for the avatar. It could be anything, it doesn't have to be anything that really matters, but if I succeed in this [task], then a can of Präriegryta [a stew traditionally served in the military] appears—Congratulations! You have now unlocked Präriegryta! A reward, which may have no impact whatsoever on my ability to solve upcoming tasks. I just think it would be fun, and it would make me wonder, what will happen next? The next thing could be: Here is a package of the Swedish Armed Forces' skin ointment, it's silly, but I think the human brain is wired to seek these kinds of rewards, and they don't have to have any real value...* [Participant 5]

Theme 2: Agency in Interaction With VPs

Agency in interaction with the VPs was discussed in terms of how participants navigate and interact with the VP environment. Participants highlighted the importance of having a sense of control over their actions and decisions within the VP environment. They mentioned that, in certain cases, they felt limited in their decision-making and movement within the environment.

Participants suggested that they would appreciate more freedom in decision-making and how they could move around in the environment. However, answering with just free-text answers was perceived as more challenging; participants suggested that such an option should be combined with listed decision alternatives, known as imposed choice [4]. Imposed choice refers to decisions made from a set of given options, which can help guide the learning process.

The participants also discussed the importance of narrative [4], which is the structured sequence of events and choices that shape the learner's experience. They believed that being able to navigate within the VP by making choices listed in the VPs, combined with an interactive free-text menu, would give them a feeling of freedom and help unfold the scenario.

In addition, the participants mentioned the importance of the agency provided by avatars. They believed that avatars could enhance the feeling of control over the environment, which could influence motivation positively:

> *Yes, like it's "high alert," okay? But there is always much more information available. How do we assess the threat level right now? Do we have an external barrier in the form of surveillance? Have we set up an alarm system? Is the terrain mined, or can they [the enemy] just walk in? I need to know that! Because I will behave differently based on this information...So, yes, the medical and tactical [scoring], it's the tactical I am talking about; that's where it's very difficult if I can't make entirely tactical decisions because the information isn't there. Or the options I would have liked are not there...* [Participant 1]

> *When it comes to graphics, I don't think it is so important in a way, I think that I value the autonomy of the player the most. For instance, I would like to be able to create something by myself if I can give a name to my character or give it my name.* [Participant 5]

> *[The interactive menu] gives you a bit more freedom if there is something else you would like to do, but the option is not there.* [Participant 9]

Theme 3: Realistic Tactical Experience

The significance of delivering authentic, realistic experiences through VPs was discussed by the study participants. They highlighted the importance of the tactical environment, which may influence their decision-making. This theme is closely related to theme 2 and how immersion in the virtual environment representation can support the users' sense of agency. Participants frequently mentioned the visual detection of potential threats or enemies within the VP simulation as an example of realism. Multimedia elements, such as sound, pictures, and video, can enhance the feeling of presence and improve the perception of the virtual environment. Sensation [4], which involves visual and auditory stimuli, was highlighted as crucial for improving the experience. This includes virtual worlds, virtual reality, or augmented reality to engage the senses.

Participants noted that the tactical environment is constantly changing and unpredictable, often intersecting with medical decisions. This interplay makes military medical professionals distinct from civilian ones. Therefore, participants implied that the characteristics of the tactical environment should be highly visible and emphasized in the virtual environment. They suggested using multimedia elements to enhance realism and aid in understanding the tactical environment. Randomness as a game element [4] refers to the unpredictable elements introduced into the simulation, which can create a more realistic and challenging environment. This can simulate the unpredictability of real-life scenarios, making the experience more immersive and engaging. Realistic cases were perceived to enhance engagement and influence the sense of agency in the VP interaction:

> *I know what I would do, and I know what the game [VPs] would like me to do. The more the war environment and the situation is clarified, the tighter these two become. For instance [in the last case], I didn't know if they were still shooting, and that's why I decided to run into the building. If I knew, if there were people screaming, if I knew something was happening...Now my intuition told me that the shooting had stopped, so I wanted to get into the building...It is important with sound; to be able to listen the sounds of a war, someone can hear things before they come.* [Participant 3]

> *One gets already a lot of information from the picture...[referring to the second VP]. Someone can embed videos for 5-10 seconds so one gets a better idea of the patient.* [Participant 7]

Theme 4: Confidence, "I Know That the Knowledge I Have Works"

Participants felt that high scoring could increase their confidence, encourage them to continue interacting with cases, and thus enhance learning. They reflected that their previous combat casualty care training was applicable when managing the VPs and that this was reflected in their scores. Alternatively, participants commented that they needed more practice if they did not achieve the highest scores.

Adjusting the difficulty of presented educational content based on the learners' performance scores is known as difficulty adaptation [5] of the designed cases. Participants suggested that if the tasks are too challenging, they may become discouraged by low scores. Conversely, very easy cases might not challenge learners enough. Participants thought the cases were relevant to the course content, quizzing knowledge they had received, with the first and second cases being medically easier than the third one. Participants suggested that feeling unable to solve cases due to high difficulty levels could negatively influence their motivation:

> *I learned [from the VPs] that the knowledge I got from the course works [after looking at his final score].* [Participant 5]

> *Yes, it's good [the scoring]! And it is also good to get a patient that isn't possible to save. It's good to know...that you don't [always] have a chance...that you are done. But the percentage of such cases cannot be too high, because then you will lose motivation...It's the same thing when you talk about game development: if you have too much, too difficult, then people quit. They will lose interest; you have to have some "wins" too.* [Participant 4]

Theme 5: Social Influence on Motivation

Participants mentioned that scoring could be fun and enjoyable, particularly that higher scores increased their enjoyment of interacting with the VPs. They believed that social elements, such as group competition, could be motivating. Competition [4] involves encouraging learners to compete with each other. Leaderboards [5] are rankings that display the top scores of participants, motivating learners through visible performance comparisons. Participants suggested that displaying the top 3 players' scores to everyone could act as a goal for others to achieve. However, they also thought that low scores should not be visible, as this could embarrass individuals and cause demotivation. Social pressure [4] refers to the influence from peers or the community that can either motivate or demotivate learners. In this context, participants mentioned that visible scores and rankings could exert social pressure, influencing their motivation positively or negatively. While high scores and top rankings can be motivating, low scores can create negative feelings and reduce motivation:

> *I don't think that one should have everyone's score in a list, but maybe one could have a list with the ones having the highest score, let's say Gustafsson, that has 77 points. Then I want to beat Gustafsson and get a higher score and I will keep on trying. But then on the other hand, the one who is lower on the list, if I had 26 points for example out of 100, then I wouldn't like it to be visible. Then everyone would see that I have difficulties [with the game] and then I would lose motivation...I think that it would be good if the list just showed the top 3 or 5.* [Participant 5]

Theme 6: Personalized Learning

Participants highlighted the importance of personalized learning, where feedback and progression are tailored to the individual's performance. Scoring can provide personalized feedback on the number of correct decisions made during interactions with VPs. This feedback helps learners understand their current knowledge level and identify areas needing more practice.

Progression [4] refers to tracking and visualizing a learner's development and achievements over time. Participants suggested that users could log in and interact with VPs, with the system tracking their progression. This tracking allows users to see their current knowledge level and identify areas needing more practice. Participants also suggested receiving personalized material to practice based on previous performance. This feature aligns with the game elements of scoring and progression, where specific feedback on progress influences participants' confidence levels and personalized learning paths.

Furthermore, the system could enable users to repeat specific decisions after receiving negative feedback, promoting mastery in learning by allowing users to retry and improve their scores. Renovation [4,31] allows users to face the consequences of their actions and try again once their previous actions have failed. The participants perceived positively the fact that they could have a second chance to make a new decision, after failing with the first one, because it enabled them to realize wrong decisions and improve them.

Finally, participants suggested that they would be willing to practice decision-making with a library of VPs that offer a mix of varying levels of difficulty, allowing for continuous and adaptive learning experiences:

> *I learned [from the VPs] that I need to practice more...One can complete the VP and get some form of assessment about the performance and then receive tasks to do.* [Participant 1]

> *The scoring could be a way to see how well you are doing and someone could perhaps log in and see next time maybe that there are new things and tasks to do. The scoring can provide information about whether one has improved or is at the same level, so that I think it can be a good thing and that one might get a personal login or something so that one can follow the statistics on.* [Participant 9]

> *It is very good that one is given the option to try things again after one gets to know what the problem is. Because sometimes one has been making the wrong decision and one continues in the same direction [without noticing the mistake]. Here one knows, ok this is wrong, I am going to try again and make another decision…. I think it is good to get feedback immediately after making a mistake, and then provide them again with different decision alternatives. But it should not give away the right answer, like stopping the bleeding, directly, because then it becomes too easy.* [Participant 11]

Discussion

Principal Findings

This study investigated how to design VPs with game elements for Swedish military medics. The interaction analysis of the think-aloud sessions, structured with the uPEA framework, and the thematic analysis of interviews provided insights about the participants' interactions and design preferences. The insights gained may encourage designing VPs with game elements, as well as integrating errors that may support military medics' reflections and decision-making.

Overall, the VPs were positively received and effectively highlighted problems, leading to reflection and discussion. In the first VP case, the medics were confused; they lacked awareness of possible threats posed by the tactical environment and injured themselves by rushing to help patients. A shift was noted where most medics became tactically more aware, resulting in improved tactical decisions in the second and third VP cases. It is likely that the medics realized the consequences of their wrong tactical decisions in the first VP and applied this experience in the second and third VP. This observation shows the potential of VPs as an educational aid to support learning of situational awareness. This pattern was not observed in medical decision-making due to the varied medical challenges in each case, preventing the transfer of insights from one VP to another.

While analyzing how the participants explained their mistakes, we observed that some participants showed reluctance to accept their mistakes, attributing errors to the limitations of the VPs, such as the absence of 3D pictures and audio. They emphasized the importance of authentic and realistic experiences, particularly in detecting potential threats. For instance, being able to visually detect potential threats and enemies in the VPs was frequently mentioned as an example of "realism." While the 2D pictures and lack of sound do limit the presentation of the environment, this expectation may diverge from the reality of actual military operations, where threats often may remain concealed or unexpected. This raises the question about the role of realism in educational simulations and how fidelity to real-world conditions is realized in simulations [32].

Realism, although highlighted as important by the participants, is not the overall goal of simulation. Using various techniques that enable reflection to support decision-making may be more important. A study by Massoth et al [33] observed that high-fidelity simulation led to equal or even worse performance as compared with low-fidelity simulation. A previous systematic review noted that "presenting realistic patient scenarios with a great degree of freedom cannot be an excuse for neglecting guidance in relation to learning objectives" [17]. In some cases, "departing from realism" can enhance the quality and effectiveness of training by allowing participants to have a second chance, repeat scenarios after debriefings, or slow down the deterioration of a patient to provide time for reflection [34].

Although feedback and prompts for corrective actions may reduce the "realism" of field conditions—where consequences of wrong decision-making may not come with a possibility of correction—it was perceived positively by the participants. Feedback helped them recognize poor decision-making and personalized the learning experience. Unlike dialogue-oriented VPs, which primarily simulate clinical encounters through scripted interactions, our study's VPs enabled reflection by allowing participants to analyze their decisions and learn from their mistakes.

Purposefully selected multimedia elements, such as pictures, audio, and videos, can enhance the perceived realism and participants' understanding of the tactical environment. In our study, we used the generative AI application DALL-E [24] to generate realistic patient images in various simulated contexts. Such educational use of the new generation of artificial intelligence tools in VP design has been suggested also elsewhere [35] and seems to be a viable solution to increase realism, situation awareness of the simulation, and learner emotional engagement. Emphasizing the characteristics of the military environment in simulations was perceived as important in our study, as it allows participants to practice dealing with consequences that might be challenging to face in a live simulation.

Some of the participants mentioned feeling constrained while navigating in the VPs because of the limited number of listed decision alternatives they had to choose from. An interactive menu, where one can type in keywords, or a complementary free-text box could enable participants' wish for agency in decision-making, combined with several listed decision alternatives. In addition, participants mentioned that they value the agency in the interactions with the VPs, for instance, to be able to navigate freely in a virtual environment. Avatars were discussed as a positive feature to enhance motivation and the feeling of controlling the environment.

VPs effectively highlighted errors by showing the negative consequences of suboptimal choices, scoring performance, and providing textual feedback after decisions. What initially seemed like a limitation—such as the lack of sound and videos, which might lead to an incomplete understanding of the tactical environment—actually promoted participants' imagination and creativity. Many participants progressed from recognizing errors to reflecting on explanations and considering alternative solutions. Similarly, a previous study found that facilitators helped learners shift from focusing on explanations to generating alternative solutions by dramatizing scenarios [26].

In our study, the think-aloud sessions supported this reflection. To more effectively raise users' levels of reflection, VPs could be designed to prompt learners to consider why a mistake was made and think about next steps before presenting optional paths. Reflective practice and feedback, crucial for developing expertise, have been emphasized in several studies and align well with our findings [36,37]. VPs allow users to make mistakes and receive feedback, providing valuable opportunities for reflection on decision-making. Studies suggest that feedback in VPs can positively influence learning outcomes [17,38].

The participants also argued for various game elements that they believed would enhance the learning experience by making it more enjoyable, increasing their confidence, and providing reassurance that they were making the right decisions. These elements included scoring, badges, virtual goods, progress bars, performance tables, content unlocking, hints, challenge, control, imposed choice, narrative, avatars, sensation, randomness, difficulty adaptation, competition, leaderboards, social pressure, progression, and renovation.

Feedback was suggested to be realized in the way of providing hints for the correct answer and not giving away the right answer directly. Scoring and feedback can add a personalized dimension to learning; participants suggested that they would like to have access to several short cases to be able to log in to the VP platform and receive challenges in the form of new cases to solve. Personalized feedback would allow them to train competencies based on their performance, while it would allow them to monitor their progress and understand which competencies they need to train and improve. Visual progress bars depicting progression and achievements in medical and tactical decision-making were suggested as an alternative to visualize scoring by the participant.

Scoring of the users' performance was viewed as an element that can motivate users to keep on trying to improve. Although all participants agreed that scoring is a useful feature, many of the participants had not noticed the scores in the VP cases of this study as the scores were not placed in a prominent place on the screen. Scoring has been previously used in studies in various forms, to inform the participants about their progress. In a previous study, scoring was presented in the form of a trauma score [39], tracking the management of the trauma patient. Achatz et al [40] used a similar concept, presenting scores in the form of "health points" to depict how well the patient responded to the decision-making and events taking place in the game. Participants suggested that obtaining good scores makes the learning experience enjoyable and adds confidence, as it indicates that the knowledge they acquired during their training is useful. Similarly, previous studies have demonstrated that scoring-based game mechanics effectively motivated players and enhanced their learning engagement in a Swedish emergency department game [41].

According to the study's participants, displaying the third to fifth top scores to everyone can motivate learners to compete with each other, reflecting the concept of leaderboards. However, participants also noted that displaying less successful performance in the form of low scores could undermine the learners' reputation and lead to negative feelings. Social aspects and gaming preferences may vary across different cultures and professions. Some participants suggested integrating competition into VPs to increase motivation. However, other studies have reported that stakeholders in emergency medicine believe competition is not aligned with the culture of health care professionals [41]. Future studies should therefore carefully consider the target end users when designing and implementing competition as a game element.

Participants suggested that future efforts could focus on developing a VP repository with short cases and supporting the creation of VPs tailored to different levels, roles, and experiences of Swedish Home Guard members. Such VP repositories already exist for general medicine [42], and the idea could be transferred to military medicine education. This approach could further explore the potential of accelerating the design of VPs. In addition, future research could examine whether the design principles and game elements are applicable to other military medicine professionals and across different cultural and operational contexts.

According to the literature, serious games may improve performance in life-saving interventions on the battlefield [43,44]. Future research should investigate how gamification and specific game elements can enhance learning outcomes and the long-term retention of skills and knowledge acquired through gamified VP interactions.

We acknowledge that the context and culture of Swedish military medics may not fully generalize to other military or medical training environments. Moreover, the number of participants was limited (14) and therefore caution should be taken when considering how findings may transfer to other contexts. However, it is important to note that this study is qualitative in nature, where the depth and richness of the data are prioritized over the sample size.

While the uPEA framework might suggest that mistakes were the primary focus of the interaction analysis, we used it to understand how participants became more creative and reconsidered decisions when reflecting on mistakes. These insights could inform future VP designs.

The reflexive thematic analysis followed the 6-step approach suggested by Braun and Clarke [30]. While this is an established and flexible approach, it is highly interpretive, encouraging the experiences of the researchers to influence and inform the themes. Although this subjectivity can affect the consistency and replicability of the findings, it also serves as a strength in the context of this study. Our experience and familiarity with gamification strategies allowed coding game elements and informing the developed themes within the semistructured interviews. This capability was crucial, given that the participants were not well familiar with gamification terminology and thus unable to explicitly name these elements themselves. Through the reflexive thematic analysis, our study draws out implicit references to game elements and interprets discussions around participant experiences that are aligned with gamification concepts. This approach leverages the inherent subjectivity of our analysis to produce deeper insights that might otherwise be overlooked by the use of other methodologies.

Conclusions

Gamification has the potential to enhance VP design and offer flexible learning opportunities to support the education and training of Swedish military medics. The uPEA framework provides a useful lens for understanding decision-making during interactions with VPs, helping to inform how mistakes followed by feedback in VPs can promote reflection and creativity.

Game elements may effectively leverage the potential of VPs by fostering motivation, enabling personalized learning, supporting agency, and enhancing the confidence of military medics. Emphasis may be placed on representing austere aspects and consequences of the tactical environment. Incorporating opportunities to make errors followed by direct, constructive feedback mechanisms in the VPs may further enhance learning outcomes, encouraging critical reflection and continuous improvement.

Acknowledgments

The authors would like to express their gratitude to the participants of the TCCC-CLS course for their invaluable contributions during the think-aloud sessions and interviews. Special thanks are extended to Charlotte Silén and Karl Hybinette for their efforts in testing the virtual patient cases and providing essential feedback. The authors also wish to acknowledge the support of the Home Guard of Sweden (Hemvärnet) in facilitating this study. They extend their sincere appreciation to Lukas Berg, a certified instructor in combat casualty care, for his valuable role in developing the content of the VPs. In addition, they are grateful to Martin Olsson, a course leader in the Home Guard, for his pivotal contributions to the development of the VPs and for granting us access to the course participants. This study is financially supported by the Swedish Armed Forces. The ToC image was generated with the assistance of artificial intelligence and is one of the images used within the virtual patients. The authors have reviewed and approved the final output.

Conflicts of Interest

None declared.

Abstract

Background: Attention-deficit/hyperactivity disorder (ADHD) usually begins in childhood and is often accompanied by impairments in social functioning. Virtual reality (VR) has emerged as an adjunctive tool to embed in social skills training to enhance the social skills of children with ADHD, but its effectiveness requires further investigation.

Objective: This study aims to enhance the social skills of children with ADHD by examining the feasibility and effectiveness of VR-based training in comparison to traditional social skills training.

Methods: A 3-arm randomized controlled trial was conducted with 90 children with ADHD aged 6-12 years. Participants were randomly assigned to 3 weeks of 12-session VR-based social skills training, traditional social skills training, or a waitlist control group of equivalent duration. Outcome measures included assessments by a clinical psychologist who was blinded to group assignments, the Social Skills Improvement System Rating Scale, the Behavior Rating Inventory of Executive Function, and the Simulator Sickness Questionnaire, conducted at baseline and after the intervention.

Results: The preliminary results support the feasibility and acceptability of VR training for children with ADHD aged 6-12 years. Analysis showed that the VR and traditional social skills training groups experienced a statistically significant improvement in the clinical psychologist assessment of social skills and parent-rated self-control, initiative, and emotional control after the intervention compared with baseline. The VR group performed significantly better than the traditional social skills group on social skills assessed by clinical psychologists ($F_{2,85}$=76.77; P<.001) and on parent-rated self-control ($F_{2,85}$=18.77; P<.001), initiative ($F_{2,85}$=11.93; P<.001), and emotional control ($F_{2,85}$=17.27; P<.001). No significant between-group differences were found for parent-rated cooperation and inhibition (all P>.05).

Conclusions: The findings provide preliminary evidence supporting the feasibility and superior effectiveness of VR-based social skills training compared to traditional approaches for enhancing social skills and related executive functions in children with ADHD. These results suggest that VR may be a valuable tool to embed within social skills interventions for this population. Further research is warranted to explore the long-term impacts and generalizability of these benefits.

Introduction

Overview

Attention-deficit/hyperactivity disorder (ADHD) is one of the children's most common neurobehavioral disorders [1], with a global prevalence of 5.3% [2] and a prevalence of 7.6% among children aged 3-12 years [3]. Inattention, impulsivity, and hyperactivity are the 3 main categories of ADHD symptoms, which are associated with nontypical cognitive and behavioral functioning due to their influence on the regulation of emotions and brain networks. Persistent patterns of inattention, impulsivity, and hyperactivity that interfere with daily functioning are considered ADHD [4]. Meanwhile, these symptoms may contribute to social difficulties and peer problems due to a deficit in social executive function skills [5].

Children with ADHD often experience specific social skills difficulties that can affect their interactions and relationships with others [6]. These children may struggle to think before acting, leading to impulsive behaviors that can disrupt conversations or be seen as socially inappropriate [7]. They may have difficulty considering the consequences of their actions, leading to difficulty in maintaining self-control during social interactions. They also have trouble sustaining attention during conversations and missing important details or cues [8]. They often move excessively, are restless, or have difficulty staying in a particular place, making it difficult to actively participate in group activities, take turns, or engage in cooperative play [9]. Furthermore, difficulty regulating emotions can affect social interactions in children with ADHD [10], leading to outbursts of anger, frustration, or impatience. These emotional challenges can strain relationships with peers and make it difficult to respond effectively to social situations. This persistent social impairment can lead to peer rejection and exacerbate academic failure, depression, and anxiety [11,12]; thus, addressing social impairment during childhood is critical.

Social skills training is one of the ubiquitous approaches to ameliorating social behaviors in people with ADHD. The training usually involves a combination of didactic instruction and role playing activities [13]. Effective social skills interventions offer strategies and support to help children with ADHD improve their social competence, navigate social situations better, and foster positive relationships [14]. However, this method may be restricted by time and space, and imagining actual situations during training is difficult for children with ADHD.

Virtual reality (VR)–based interventions are considered an effective alternative to traditional social skills training, providing the immersion of a digital environment and engaging users in the learning process [15]. VR can produce various scenarios that are not easily and safely operated in contrast to equivalent real-life training programs [16,17]. Typical VR-based interventions for ADHD use immersive digital environments that simulate real-world social and academic situations. For example, these interventions may place the child in a classroom setting with various auditory (eg, classmates chatting and teacher lecturing) and visual (eg, posters on walls and other students moving around) distractions [18,19]. By requiring the child to maintain focus and inhibit responses to these distractions within the VR environment, the intervention aims to improve their inhibitory control and attention regulation skills [20]. The VR setting allows the child to practice these skills in a safe, controlled space without the consequences of real-world mistakes.

Additionally, VR interventions may present the child with digital social scenarios, such as interacting with digital peers or authority figures. These scenarios allow the child to observe and practice appropriate social behaviors, like taking turns, making eye contact, and responding to social cues, which can be challenging for children with ADHD [21]. Immediate feedback and the ability to repeat scenarios within VR can help consolidate these social skills.

By incorporating these types of immersive VR environments, the interventions leverage the unique affordances of VR to target the core cognitive, behavioral, and social deficits associated with ADHD engagingly and safely. Social skills training using VR technology exists, and the efficiency of such applications has been demonstrated; however, beneficiaries are mainly those with autism spectrum disorders, schizophrenia, and intellectual disabilities [22-25]. A VR-based intervention to enhance the social interaction skills of children with ADHD is limited, and its effectiveness has not been empirically studied.

Theoretical Background

The VR-based social skills intervention is rooted in social learning theory, as developed by Bandura [26]. Social learning theory posits that individuals can acquire new behaviors, attitudes, and emotional responses by observing the actions and consequences experienced by others [27]. This observational learning process is a key mechanism by which children develop social competence and navigate complex interpersonal situations. For children with ADHD, deficits in social skills are often linked to challenges with attention, impulse control, and emotional regulation—factors that can hinder their ability to effectively observe, process, and learn from social cues and interactions [28]. The immersive nature of VR provides an ideal platform to address these challenges and leverage the principles of social learning theory [15].

Within the VR environment, children with ADHD can observe modeled social behaviors and their consequences in a safe, controlled setting. This allows them to focus on the relevant social cues and responses without the distractions or anxiety that may arise in real-world interactions [29]. The VR-based intervention can facilitate observational learning and cognitive processing of adaptive social behaviors by presenting diverse social scenarios and modeling appropriate social skills.

The VR-based intervention incorporates opportunities for active practice and role playing of these observed social skills. This aligns with Bandura's emphasis on the importance of engaging in enactive learning, where individuals have the chance to rehearse and refine new behaviors [26]. The immediate feedback and reinforcement provided within the VR environment can further support the acquisition and consolidation of social skills. Importantly, social learning theory also highlights the role of self-efficacy—an individual's belief in their ability to successfully execute a behavior [29]. By providing a supportive, scaffolded learning environment in VR, the intervention aims to enhance children's confidence and self-efficacy in navigating social situations, ultimately promoting the generalization of social skills to real-world contexts.

By incorporating social learning theory [26] into VR-based social skills training, an effective and engaging learning environment that aligns with the unique needs and challenges of children with ADHD can be provided. The VR-based approach leverages the power of observation, modeling, reinforcement, and cognitive processes to promote the acquisition and generalization of adaptive social skills, empowering children with ADHD to navigate social interactions with greater confidence and success.

Rationales of VR-Based Social Skills Training for ADHD

While traditional social skills training has been used to help children with ADHD, they may be limited by logistical constraints and difficulty simulating real-world social scenarios [13,14]. VR technology offers a promising alternative, as it can immerse participants in customizable social environments that are difficult to replicate in physical settings [15-17]. VR-based interventions have been shown to effectively target social skills deficits in populations such as autism spectrum disorder and schizophrenia [22-25].

However, research on the use of VR-based social skills training for children with ADHD is limited. A few existing studies have focused on using VR to address ADHD symptoms like inattention and impulsivity but have not specifically examined the impact on social skills [30]. Given the unique social challenges faced by this population and the potential benefits of VR-based training, there is a clear need for rigorous investigation into the feasibility and efficacy of VR-based social skills interventions for children with ADHD.

This study aims to address this gap by examining the feasibility and effectiveness of VR-based social skills training for children with ADHD, in comparison to a traditional social skills training approach and a waitlist control group. Drawing on social learning theory, the VR-based intervention is designed to leverage the immersive, engaging features of VR to enhance observational learning, skill practice, and self-efficacy in navigating social situations. Findings from this randomized controlled trial (RCT) will provide valuable insights into the potential of VR-based interventions to improve social competence in children with ADHD.

Methods

Study Design

In this study conducted at The Hong Kong Polytechnic University (ClinicalTrials.gov NCT05778526), a 3-arm RCT was implemented from November 2023 to February 2024. The participants were assigned randomly to 3 groups: the VR training group, the traditional social skills training group, and the waitlist control group, maintaining a 1:1:1 ratio. The VR training group received 12 sessions for 3 weeks, with each session lasting 20 minutes. Similarly, the traditional social skills training group also underwent 12 sessions in 3 weeks, with each session lasting 20 minutes. These intervention durations and frequencies align with the findings of a study by Willis et al [14], which reported intervention durations ranging from 2 to 12 weeks and weekly time commitments of 60-90 minutes. Therefore, the chosen intervention duration and frequency in our study are considered appropriate based on existing research. Participants randomized to the waitlist control group were offered VR training after 1 month when data were collected. The guardians of the participants were reminded to attend the training via phone in the first 4 sessions and then via WhatsApp (Meta Platforms) or WeChat (Tencent Holdings Ltd) in the fifth and eighth sessions, respectively. There were no follow-up reminders issued in the following 4 sessions. The protocol of the RCT was published [31]. The study followed the CONSORT (Consolidated Standards of Reporting Trials) guidelines (Multimedia Appendix 1).

Ethical Considerations

This study received approval from the institutional review board at The Hong Kong Polytechnic University (HSEARS20221221003) and was conducted from November 2023 to February 2024. It adhered to the principles outlined in the Declaration of Helsinki, which included ensuring participant anonymity and obtaining informed consent from the guardians of the participants. Participation was voluntary. Informed consent was obtained through a clear process, ensuring that guardians fully understood the study's purpose, procedures, and potential risks. Participants were also given the option to withdraw from the study at any time without penalty. Data collected during the study were anonymized to protect participant confidentiality.

Recruitment

Participants were recruited from the children and youth community centers through extensive advertising, including posters and advertisements on social media. A web-based registration form was created for the interested guardian to register. Interested guardians who provided written informed consent were further evaluated for inclusion and exclusion criteria.

Eligibility criteria for participants were as follows: (1) aged between 6 and 12 years; (2) Chinese ethnicity; (3) residing in Hong Kong; (4) having received a diagnosis of ADHD by Child Assessment Service in Hong Kong or via private practice; (5) stable on pharmacological and psychological treatment for ADHD 8 weeks before baseline (determined by health care professionals based on medication data and behavioral observation); (6) no initiation or change of pharmacological treatment for ADHD during the intervention period; (7) ability to read Chinese and speak and listen to Cantonese by the child and by at least one of their legal guardian; and (8) willing to provide informed consent by the participants' legal guardians.

Exclusion criteria were as follows: (1) comorbid autism; (2) mental health disorders; (3) an estimated IQ lower than 85 (using the Wechsler Intelligence Scale for Children—Fourth Edition); (4) autism spectrum disorder (previously diagnosed by health care professionals), (5) comorbid acute psychiatric disorder (previously diagnosed by health care professionals); and (6) severe physical disability (eg, blindness, deafness) or learning disability (eg, dyslexia).

Procedure and Interventions

Potential participants' guardians completed a telephone prescreening. Following consent, the guardian showed the diagnosis of ADHD of the participants and completed the baseline assessment for the participants. The randomization was conducted using a computer-generator randomizer to generate the random allocation list. The randomization was undertaken by another research assistant not directly involved in the study. A number generated by the computer will be assigned to each eligible subject who will be randomly allocated to the 3 different groups by using the number.

VR Training Group

The VR training aimed to enhance the social interaction skills of children with ADHD. Participants in this group wore a head-mounted display and 2 controllers during the training. The intervention included three real-life scenarios, including (1) a classroom and playground, (2) a mass transit railway station and carriages, and (3) a supermarket and restaurant (Multimedia Appendix 2). These scenarios were purposefully designed to simulate real-life social situations, allowing participants to practice and refine their social skills in a controlled and supportive digital environment. Gamification elements were integrated into the immersive VR training, including dynamic simulations and real-time feedback to provide immediate correction of participants' behaviors.

Each scenario contained approximately 20 or more tasks for the participants to complete. Participants underwent 1 scenario in 1 session. The sequences of the scenarios used in each session were the same for all participants. Each session lasted for a maximum of 20 minutes to ensure the concentration of the participants and prevent any physical effects [32]. The duration was adjusted subject to the emotions of the participants during the training. During the intervention, a research assistant guided the participants in completing the tasks. Multimedia Appendix 3 shows the participants conducting the intervention.

Traditional Social Skills Training Group

Participants in this group were educated in social skills through traditional methods, including role-playing activities and didactic instruction. Four modules, including (1) how to introduce yourself and basic social skills, (2) how to listen to others, (3) how to share with others, and (4) learning to know how people feel and how to empathize, were covered in the training, which has been adopted in previous studies [33]. Each participant was taught by 1 instructor. The content of the training and the duration of each session were kept similar to the VR training group.

Waitlist Control Group

Participants in this group received no training and were not allowed to change or initiate their medical treatment during the study period.

Outcome Measures

Data were collected at 2 time intervals, including baseline (T1) and immediately after the last sessions (T2) to determine the feasibility and effectiveness of the RCT.

Primary Outcome: Social Skills

The social skills of the participants were evaluated by the guardians of the participants and a clinical psychologist. The guardians rated using the Social Skills Improvement System-Rating Scales, which has been validated in children with ADHD [34]. A total of 31 items were selected from the self-control, initiative, and cooperation subscales of the Social Skills Improvement System–Parents. The clinical psychologist used a modified version of Riggio basic social skills assessment [35] to evaluate the participants. This involved a 20-minute conversation in which the clinical psychologist observed and assessed their social skills. To minimize unblinding bias during the assessment, each participant will be identified by a case number.

Secondary Outcome

Executive Functioning

The executive functioning of the participants was measured by the subscale of inhibition (16 items) and emotional control (10 items) of the Behavior Rating Inventory of Executive Function-Parents, which is useful in Chinese children with ADHD [36]. The executive functioning of the participants was evaluated by the guardians of the participants.

Motion Sickness

The motion sickness or physical discomfort of subjects using the VR was measured by the Simulator Sickness Questionnaire [37], which was administered at T2 to the participants in the VR training group only.

Satisfaction

Satisfaction with training was measured by a 7-point Likert scale administered at T2 to the VR training group.

Feasibility and Acceptability Outcomes

Feasibility was assessed through participants' retention of the intervention. The attendance of the participants during the interventions was recorded, and absence from any training session was considered nonadherence.

Justification of Sample Size

A sample size of 20 subjects per group can attain at least 80% power and 90% confidence according to the study of Whitehead et al [38]. We intended to recruit 90 participants (30 per group), assuming a conservative attrition rate of 25% to 30% [19], to reliably determine these outcomes.

Statistical Analysis

All statistical analyses were performed in the SPSS (version 28, IBM Corp) software and were 2-sided with a level of significance of $P<.05$. The data analysis complied with the principles of intention-to-treat analysis. The subjects' demographic information was summarized into categorical variables with frequency and percentage. The change between T1 and T2 of each group was tested by a 2-tailed *t* test. Analyses of covariance (adjusted for possible confounding factors) were conducted to evaluate the within-group effects and between-group effects in terms of outcomes. Effect sizes were measured by Cohen *d* and 95% CI. To assess the improvement during the intervention period among the 3 groups, *F* tests were performed on primary and secondary outcome measures at T1 and T2.

Results

Participant Characteristics

Between November 2023 and February 2024, we enrolled 108 participants in our study. However, 10 participants were excluded before randomization due to not meeting the inclusion or exclusion criteria, and 8 declined to provide written consent. Consequently, 90 participants, along with their guardians, agreed to participate in the study. These participants and their guardians agreed to join the study and were randomly assigned to the VR training (n=30), traditional social skills training (n=30), or waitlist control group (n=30). Baseline characteristics were balanced among the 3 groups without statistically significant differences (Tables 1 and 2). The mean age for the VR training, traditional social skills training, and waitlist control groups were 8.63 (SD 1.90), 8.30 (SD 1.70), and 8.67 (SD 1.45) years, respectively. All participants attended mainstream schools. Table 1 presents the participants' baseline demographic characteristics and outcome measure scores, respectively.

[a]VRT: virtual reality training.

[b]TSST: traditional social skills training

[c]WLC: waitlist control group.

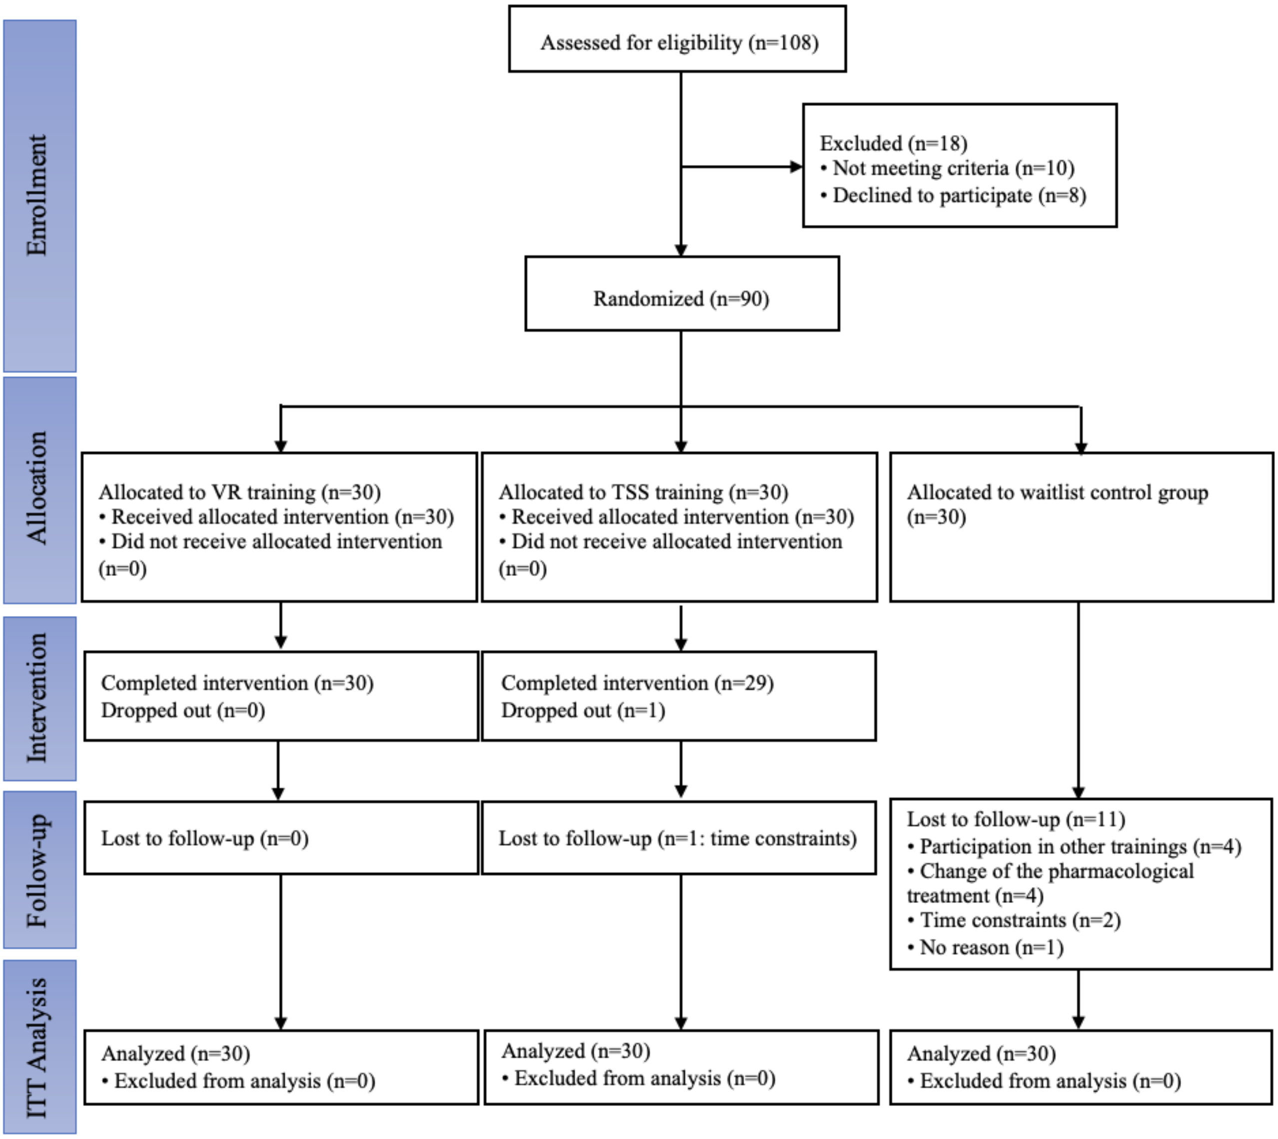
[d]Higher scores indicate better social skills.

[e]Higher scores indicate poor executive functions.

[f]Heterogeneity variance between independent groups was assessed using Levene test (*P*>.05 indicates no significant difference in variances).

During the training, all participants in the VR training group attended 12 sessions, 1 participant in the traditional social skills training group withdrew after 3 sessions due to time constraints, and 11 participants in the waitlist control group withdrew due to participation in other similar trainings, change of the pharmacological treatment, time constraints and loss to follow (Figure 1). Findings provided promising evidence of participants' acceptance of the VR training.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. ITT: intention-to-treat; TSS: traditional social skills; VR: virtual reality.



Effects of the Interventions on Outcomes

The mean scores for the clinical psychologist assessment of social skills and parent-rated executive functioning and social skills of the 3 groups at T1 and T2 are illustrated in Table 2. Significant improvements between T1 and T2 in the VR training group and the traditional social skills group in terms of clinical psychologist assessment of social skills and parent-rated self-control, initiative, and emotional control were found. Significant deterioration of parent-rated inhibition was also found. No statistically significant difference between T1 and T2 was found in the 3 groups in terms of parent-rated cooperation. In consideration of confounding variables, the assumption of normality, that is, homogeneity of variance between independent groups, was met in clinical psychologist assessments of social skills and parent-rated self-control, initiative, cooperation, and emotional control.

Clinical psychologist assessments of social skills had a statistically significant difference between groups ($F_{2,85}$=76.77; P<.001), in which the VR training group was 7.57 higher than the traditional social skills training group (d=1.50, 95% CI 0.91-2.07) and 13.70 higher than the waitlist control group (d=3.29; 95% CI 2.50-4.06).

A statistically significant difference was found between groups ($F_{2,85}$=18.77; P<.001) regarding parental ratings of self-control, with the VR training group being 1.40 higher than the traditional social skills training group (d=0.44; 95% CI –0.08 to 0.95) and 1.83 higher than the waitlist control group (d=0.44; 95% CI –0.08 to 0.95). Parent-rated initiative had a statistically significant difference between groups ($F_{2,85}$=11.93; P<.001), in which the VR training group was 0.93 higher than the traditional social skills training group (d=0.24; 95% CI –0.27 to 0.74) and 1.53 higher than the waitlist control group (d=0.40; 95% CI –0.11 to 0.91). Parent-rated cooperation had no statistically significant difference between groups.

For parent-rated emotional control, the VR training group was 1.15 lower than the traditional social skills training group (d=–0.40; 95% CI –0.91 to 0.11) and 2.80 lower than the waitlist control group (d=–0.69; 95% CI –1.20 to 0.16), and this difference was statistically significant ($F_{2,85}$=17.27; P<.001). The determination of parent-rated inhibition was not feasible due to significant heterogeneity in variance between the independent groups.

Regarding cybersickness in participants in the VR training group, no participant reported discomfort, fatigue, headache, eyestrain, nausea, difficulty concentrating, blurred vision, and dizziness during and after the training. A total of 16 participants were sweating during the VR training. All participants were satisfied with the VR training (mean 6.77, SD 0.43).

Discussion

Principal Findings

To our knowledge, this is the first RCT to evaluate the feasibility and acceptability of social skills training for children with ADHD developed through VR technology and clinically assessed by an independent clinical psychologist. Acceptance and satisfaction with the VR training by participants were high. Our findings showed that participants in the VR training and traditional social skills groups experienced significant improvements in social skills, self-control, initiative, and emotional control. Compared with the traditional social skills training group, the VR training group improved more in social skills, self-control, initiative, and emotional control. These results are preliminary; however, the results may be considered useful given their positive impact on social skills and executive function in children with ADHD.

Comparison With Prior Work

The findings match those observed in earlier studies that VR-based social skills training and traditional social skills training could improve the social skills of children, and VR-based intervention had a better performance than traditional social skills training [25,39]. The results suggest that VR-based interventions may be a promising approach for helping children with neurobiological disabilities, such as ADHD and autism spectrum disorder, acquire social skills due to the immersive and engaging nature of VR. Previous meta-analyses have shown that VR-based interventions are effective in improving cognitive function (ie, learning and attention) in children with ADHD [19,40,41], although these comparisons require caution due to the different purposes of the training and intervention protocols. The focus of our VR training program was to improve children's social skills, rather than improving their cognitive function as in previous studies.

The result of VR intervention containing significant improvement in the self-control of children with ADHD seems to accord with the study of Witowska et al [42], which suggested that VR interventions can promote sustained focus and attention, which are essential components of self-control, by presenting engaging and visually stimulating tasks. The immediate feedback loop generated by the VR system can help children with ADHD understand the relationship between their behaviors and outcomes, facilitating self-monitoring and self-regulation. VR interventions can promote self-control by reinforcing desired behaviors and highlighting the impact of impulsive or impulsive actions.

This study found that VR-based intervention could improve the initiative of children with ADHD. This may be attributable to the sense of autonomy and self-determination that VR provides, allowing children to make choices and decisions within the digital environment [43]. The opportunity to experience success and skill development through VR-based feedback and reinforcement can also boost children's confidence and willingness to initiate social interactions [39,44]. Additionally, interaction with digital characters or avatars may foster a sense of relatedness and social connectedness, encouraging children to practice and refine their social skills within the VR environment [45].

Contrary to expectations, no significant differences were found between VR training and traditional social skills training in terms of inhibition and cooperation. This differs from previous suggestions that digital classroom remediation could improve the inhibition of children with ADHD [18]. The absence of peer involvement in this study, as opposed to the successful peer interactions emphasized in prior research [46], maybe a factor contributing to the lack of differentiation between the 2 training approaches in enhancing cooperation. Further research is needed to directly compare the effects of VR-based interventions on self-control, initiative, inhibition, and cooperation across diverse populations, including children with ADHD, individuals with autism spectrum disorder, and neurotypical adults, to elucidate the specific mechanisms and contextual factors that influence the efficacy of VR-based approaches for different groups.

While the results of this study appear to be consistent with the previous studies on the positive effects of VR-based intervention on emotional control [47,48], it is important to note that the current sample of children with ADHD may respond differently to the VR intervention compared to other populations, such as individuals with autism spectrum disorder or neurotypical adults. Differences in cognitive profiles, developmental stages, and specific challenges faced by these groups could lead to variations in the effectiveness of the VR-based approach.

It was suggested that VR can evoke emotional experiences through a sense of "being there" in the digital environment [49]. VR alters individual experiences by motivating users to try new things and allowing them to alter habitual emotional responses [50]. The sample groups of previous studies were different from ours in that their participants were adults and older adults; thus, the analyses must be interpreted with caution. Further research is needed to directly compare the effects of VR-based interventions on self-control and related outcomes across diverse populations, including children with ADHD, individuals with autism spectrum disorder, and neurotypical adults. Such comparative studies would help elucidate the specific mechanisms and contextual factors that contribute to the efficacy of VR-based approaches for different groups.

An important consideration for this study is the cost-effectiveness of the VR-based social skills intervention compared to the traditional in-person approach. While a full cost-effectiveness analysis was beyond the scope of this study, we were able to gather some preliminary data on the relative costs of the 2 interventions. The VR-based intervention required 1 part-time research assistant at a rate of HK $70 (US $9) per hour to guide each participant through the digital scenarios. In contrast, the traditional in-person training involved 1 teacher with a special education background at a rate of HK $200 (US $25.74) per hour for each participant. This suggests the VR-based approach may be significantly more cost-effective, requiring less specialized personnel time per participant. Additionally, the VR equipment and software can be reused across multiple participants, whereas the in-person training requires the teacher's time for each session. This further implies the VR intervention could have lower marginal costs as the number of participants increases. While these initial cost comparisons are promising, a more rigorous cost-effectiveness analysis would be needed to fully evaluate the economic feasibility of implementing VR-based social skills training on a larger scale. Factors such as the upfront investment in VR hardware, software licensing fees, and training for research assistants would also need to be considered. Future research should explore these cost implications in more depth to comprehensively assess the economic viability of VR-based social skills interventions compared to traditional approaches.

In summary, our findings suggest that creating VR environments with different social interaction scenarios for children with ADHD may have some practical implications. VR can be particularly beneficial in improving basic social skills, self-control, initiative, and emotional control, although it was less effective in enhancing inhibition and cooperation in children with ADHD. Thus, VR may be appropriate for providing training in social skills, self-control, initiative, and emotional control. Additionally, children with ADHD reported high levels of satisfaction and motivation during short-term VR-based interventions, suggesting that VR training could be a useful first phase in assisting these children in acquiring social skills in a community setting.

Limitations

Although the effects of VR training are evident, potential limitations should be considered when interpreting the results. First, the small sample size recruited for this study may have limited the statistical power to determine differences between groups; nevertheless, this study provides important insights. Second, the design of this RCT had no follow-up period, and thus, the long-term effects after the intervention are unknown. Third, the trial was conducted with a highly specific type of population, and the results may not generalize to more complex ADHD populations. Fourth, a key limitation was that the satisfaction of the participants in the traditional social skills training group was not measured. Evaluating the participants' satisfaction, engagement, and perceptions of the traditional training approach would have provided valuable comparative insights. Without this information, it is difficult to fully assess the relative benefits and drawbacks of VR training compared to the standard intervention from the participants' perspectives. Future studies should consider incorporating participant satisfaction measures for all intervention groups to enable a more comprehensive evaluation of the different training methods. Fifth, although age differences across groups were found to be insignificant, the sample size within multiple age groups was limited, with some age groups having only 1 participant. This uneven distribution restricts our ability to conduct robust subgroup analyses to understand the differential effects of VR-based intervention versus traditional social skills training on social skills across various age groups. Given that social skills in children with ADHD are known to improve with age, this limitation highlights a significant knowledge gap in our study. Future research should aim to recruit a larger and more evenly distributed sample across different age groups to enable more detailed age-specific analyses. Finally, the sample size of this study may not provide sufficient statistical power for conducting subgroup analyses. This limitation means that our findings primarily reflect general comparisons between the intervention groups rather than nuanced insights into how different age groups respond to VR-based intervention versus traditional social skills training. Researchers should consider this limitation when interpreting our results and should design future studies with larger sample sizes to ensure adequate power for subgroup analyses.

Conclusions

This RCT investigated the feasibility and effectiveness of using VR in improving the social skills of children aged 6-12 years with ADHD. The results showed that VR training was more effective than traditional social skills training in terms of enhancing basic social skills, self-control, initiative, and emotional control. VR and traditional social skills training can enhance basic social skills, self-control, initiative, and emotional control in children with ADHD. These encouraging findings require further confirmation with large-scale interventions to determine the sustainability of the effects. Continued research in this area will contribute to the development of evidence-based practices and interventions that can ultimately improve the social outcomes and quality of life for this vulnerable population.

Abstract

Background: Adolescence is a critical developmental stage that is particularly vulnerable to the initiation of tobacco use. Despite the well-documented health risks associated with tobacco use, it remains prevalent among adolescents. Games for health are a promising strategy for tobacco prevention, using experiential and social learning theories to enhance engagement and improve behavior change.

Objective: This pilot study aims to (1) compare the social game–based program Storm-Heroes to a nonsocial program regarding adolescents' personal and social experiences and (2) examine how these experiences predict higher tobacco knowledge and perceived risks of vaping and conventional tobacco use.

Methods: In a cluster-randomized comparative design, 4 after-school sites (N=79 adolescents) were recruited in person and randomized in a single-blinded format to 1 of 2 interventions: the social game Storm-Heroes (44/79, 56%) or the nonsocial program A Smoking Prevention Interactive Experience (ASPIRE; 35/79, 44%). A study team member supervised both interventions. Data were collected at baseline, immediate follow-up, and a 1.5-month follow-up (45/74, 61% retained). Repeated measures mixed effects models were conducted.

Results: A total of 45 participants continued until the 1.5-month follow-up. Participants in the Strom-Heroes group were more likely to increase their perceived risk of vaping (B=0.40; *P*<.001), perceived risk of conventional tobacco use (B=0.35; *P*=.046), and tobacco knowledge (B=1.63; *P*<.001) than those in the control condition. The usability level of the program was related to a higher perceived risk of vaping (B=0.16; *P*=.003) and conventional tobacco use (B=0.16; *P*=.02) by follow-up. Attention to the program was also related to higher perceived risk of vaping (B=0.12; *P*=.002) and conventional tobacco use (B=0.14; *P*<.001). Distraction was not related to either perceived risk of vaping (*P*=.15) or perceived risk of conventional tobacco use (*P*=.71). In contrast, both more attention (B=0.60; *P*<.001) and less distraction (B=–0.37; *P*<.001) were related to higher tobacco knowledge.

Conclusions: The increased perceived risk of vaping and conventional tobacco among Storm-Heroes participants aligns with the program's goals of improving participants' awareness of the risks associated with tobacco use and their tobacco knowledge. However, distraction weakened the effect of the program on tobacco knowledge, indicating that emphasis needs to be placed on minimizing distraction for better outcomes. With the results of this study, researchers can work to advance the current version of Storm-Heroes and amplify engagement in the program to improve its potential for preventing adolescents' initiation of tobacco use.

KEYWORDS

tobacco prevention; vaping; combustible tobacco; risk perception; adolescent; games; social interaction

Introduction

Background

Adolescence is a critical developmental stage that is particularly vulnerable to the initiation of tobacco use [1-3]. Research indicates that exposure to nicotine during this period is associated with substantial impairments in brain growth, psychological harm, and long-term physical health outcomes [4,5]. Despite the well-known risks associated with adolescent tobacco use, the rates of use among this age group remain a concern. In 2023, approximately 28% of high-school students and 14.7% of middle-school students reported ever using a tobacco product [6,7]. Of the youth who reported ever using tobacco products, approximately 50% of them are current tobacco users [6,7]. As a result, the need for tobacco prevention is evident.

One particularly promising strategy for tobacco prevention is the application of games for health. Gameplay can include an amalgam of entertainment and education strategies to drive health behavior change [8]. On the basis of the experiential learning theory and the social learning theory, the immersive nature of gameplay facilitates a successful learning process through a playful and entertaining environment [9,10]. Game-based interventions can increase motivation, engagement, and overall sustainability of health behaviors [11]. In addition to our work, researchers have shown the success of games for health through randomized controlled trials [12-15].

Engaging gameplay has proven to be a promising avenue for tobacco prevention [16]. On the basis of a systematic review [17], most games for combustible tobacco prevention and cessation have leveraged the use of rewards and interactive activities to drive behavior change. Among these interventions, success was primarily observed in smoking cessation games rather than in prevention efforts [17,18]. In contrast, games meant for vaping or e-cigarette prevention have recently shown success. One example is a game called “Invite Only VR,” which showed improvement in e-cigarette knowledge, nicotine addiction knowledge, perceived addictiveness of e-cigarettes, and perceptions of harm [19]. In addition, 1 comprehensive game covering vaping and combustible tobacco, smokeSCREEN, improved antitobacco beliefs and tobacco knowledge [20]. These results highlight the potential success of game-based interventions.

By including various gaming elements (eg, competition, collaboration, reward, goal setting, and storytelling), games can provide flexibility in addressing different issues pertaining to tobacco use. One qualitative study for the design of tobacco prevention games examined adolescents’ gaming preferences and showcased the elements of cooperation, storytelling, and physical performance as key experiential learning elements for tobacco prevention [21]. The findings suggest that gaming elements can be combined to design an effective and engaging tool that covers the complexities of different tobacco products and addresses unique topics pertaining to this risky behavior.

A Social Game–Based Intervention

This line of research on gaming elements for tobacco prevention led to the design of a social game–based intervention, called Storm-Heroes, which is ideal for education systems (eg, schools and after-school programs). As a social game, Storm-Heroes offers adolescents the opportunity to witness and model healthy behaviors, such as rejecting tobacco, thereby promoting tobacco risk education [21]. With social gaming, Storm-Heroes relies on the social learning theory by promoting interpersonal discussions and boosting self-efficacy through the practice of skills to stay tobacco free. In addition, Storm-Heroes conveys normative feedback, influencing adolescents’ risk perceptions regarding tobacco use [21]. This aligns with the health beliefs model, which posits that psychosocial factors such as social interaction and peer pressure can promote risk perception and ultimately encourage behavior change [22]. Through these mechanisms, Storm-Heroes serves as a tool for tobacco prevention, leveraging peer influence and normative feedback to positively impact adolescents’ perceptions of tobacco use risks and improve knowledge.

Study Objectives

The purpose of this pilot study is to (1) compare the social game–based program Storm-Heroes to a nonsocial program with respect to adolescents’ personal and social experience with the program and (2) examine the role of adolescents’ experience with the program in predicting higher perceived risk of vaping, perceived risk of conventional tobacco use, and knowledge by follow-up. Table 1 clarifies the hypotheses tested in this study.

Table 1. List of hypotheses.

Types of hypothesis	Hypothesis statements
Personal experience	• Engagement with Storm-Heroes will result in higher attention, lower distraction, and higher recognition of program imagery than engagement with a nonsocial equivalent program. • Engagement with Storm-Heroes will result in perceptions of better usability, higher level of fun, better narrative quality, more enjoyment, and more creative freedom than engagement with a nonsocial equivalent program.
Social experience	• Engagement with Storm-Heroes will result in higher engagement in peer-to-peer discussions and better quality of discussions than engagement with a nonsocial equivalent program.
Tobacco-related outcomes	• Engagement with Storm-Heroes will result in improved perceived risk of vaping and higher perceived risk of conventional tobacco use (cigarettes, cigars, and little cigars) than engagement with a nonsocial equivalent program. • Engagement with Storm-Heroes will result in improved tobacco knowledge than engagement with a nonsocial equivalent program.
User experience mechanisms of change	• Personal experience factors and social interactivity will predict higher perceived risk of vaping, perceived risk of conventional tobacco use, and tobacco knowledge by follow-up while controlling for program allocation.

Methods

Study Design

To pilot-test adolescents' experience with Storm-Heroes, this study involved a 2-arm single-blinded cluster-randomized comparative trial. The pilot study was conducted in June 2021 at 4 after-school sites in Florida, and it was registered at the ClinicalTrials.gov registry, as part of a larger study (identifier: NCT02703597). Its components adhere to the CONSORT (Consolidated Standards of Reporting Trials) and CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines [23,24]. We assessed demographic information at baseline and program experience at immediate follow-up. We measured perceived risk of vaping, perceived risk of combustible tobacco use, and tobacco knowledge at baseline and 1.5-month follow-up.

A Brief Description of the Interventions

We compared Storm-Heroes with A Smoking Prevention Interactive Experience (ASPIRE), a nonsocial program that is similar to Storm-Heroes in terms of session structure and type of health content. Table 2 describes the differences and similarities in design elements for Storm-Heroes and ASPIRE. A detailed description of the intervention is provided in Multimedia Appendix 1 [25-32], which follows the Template for Intervention Description and Replication (TIDieR) checklist [33]. Multimedia Appendix 2 presents the CONSORT-EHEALTH items.

Table 2. Differences and similarities in elements for Storm-Heroes and A Smoking Prevention Interactive Experience (ASPIRE).

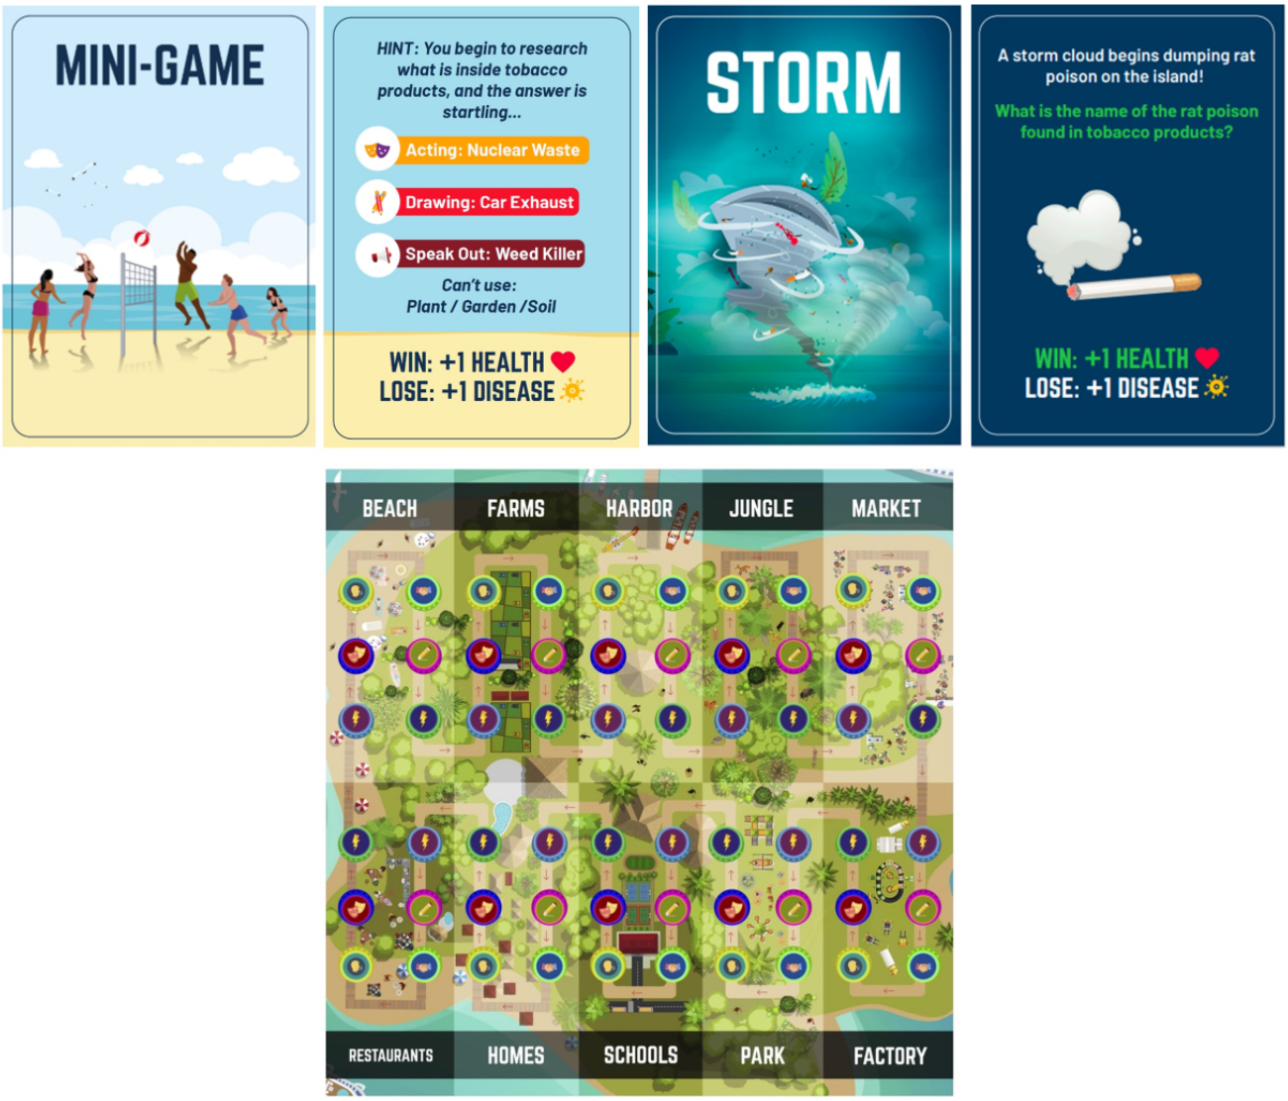
Elements	Storm-Heroes	ASPIRE	Mechanism of action
Health content based on TTM[a]	Yes	Yes	Presenting both programs with the TTM ensures that adolescents receive consistent health information and persuasive messaging based on the processes of change.
Entertainment-education videos	Yes	Yes	By leveraging narratives, these videos deliver messages that correct misconceptions about the prevalence and acceptability of tobacco use, shaping adolescents' perceptions to align with healthy norms.
Human-computer interaction	Yes	Yes	This interaction engages adolescents through a digital platform, making learning about tobacco risks engaging and interactive.
Gameplay	Yes	No	Gameplay improves engagement and provides a simulated environment where adolescents can learn through experience and build confidence.
Social interaction	Yes	No	Social interaction encourages adolescents to discuss tobacco risks and refusal skills with peers, enhancing their understanding and commitment to staying tobacco free.
Hybrid format	Yes	No	Combines online and offline activities to keep adolescents engaged and reinforce learning in various contexts.
Dosage and frequency	5 weekly sessions for 45 min each	5 weekly sessions for 45 min each	The dosage and frequency ensure that adolescents receive similar and consistent exposure for both programs.

[a]TTM: transtheoretical model.

ASPIRE is a computer-guided intervention that uses engaging videos and interactive activities across 5 sessions over 5 weeks, with each session lasting approximately 45 minutes. It aims to enhance information retention and guide adolescents toward a tobacco-free lifestyle by engaging users through text, animations, videos, and activities. ASPIRE is evidence based and tested for tobacco prevention. The intervention program is freely accessible over the web [34,35].

The Storm-Heroes intervention was developed collaboratively, involving a game designer, a research team with tobacco education expertise, and a youth design committee. Messages were designed using scientific evidence and message-framing strategies to impact tobacco risk perception, knowledge, and intention to use. The intervention aims to educate adolescents about tobacco risks, environmental consequences, and impacts on social and mental well-being, incorporating 367 unique antitobacco messages based on the transtheoretical model [36] and empowerment theory. The design process resulted in a dynamic and socially engaging educational program, Storm-Heroes, combining digital and in-person elements. It seamlessly integrates web-based components with game-based tabletop activities, including ASPIRE-derived videos and game-based social activities for group interaction (Figure 1).

Figure 1. Depiction of Storm-Heroes activities and game board.



In Storm-Heroes, adolescents engage within a narrative. They play the role of friends on an island struck by a storm bringing tobacco products, harmful chemicals, and disease. To combat the storm's effects and save their island, teams embark on quests, participating in entertainment-education videos and activities. Before engaging in the program, adolescents are grouped using a validated social network algorithm. The grouping process ensures that each participant with high intentions to use tobacco is grouped with close friends who do not intend to use tobacco, facilitating constructive support during activities. Storm-Heroes offers adolescents 5 main activities delivered on validated board game material. These include trivia with multiple-choice questions, acting where one member silently acts as others guess, drawing for guessing from sketches, speaking out for verbal clues, and teamwork scenarios presenting group dilemmas. The activities aim to engage teams in collaborative problem-solving around tobacco-related topics. Multimedia Appendix 1 describes the activities and how they are presented to players. The materials of Storm-Heroes include informative background information in game-based social activities, such as scripts and task instructions, a tabletop game board, decks for board game cards, dice, tokens, and pons. The materials can be accessed by reaching out to the researchers.

Both ASPIRE and Storm-Heroes cover a comprehensive list of health topics related to tobacco, including its composition, effects on the body and brain, environmental impact, and strategies for tobacco prevention and advocacy (Multimedia

Appendix 1). The content is structured consistently across both programs, covering aspects from understanding tobacco to building skills for a tobacco-free lifestyle and community activism.

Ethical Considerations

The institutional review board for human subject research at the University of Florida approved this study (IRB201903082). Adolescents and their parents were informed of the study's purpose and procedure. They provided written informed parental consent and written informed child assent. During data collection sessions, participants were reminded of the study purpose, procedures, risks, and that they could withdraw from the study at any time. Participants completed the surveys in a private classroom with supervision. Participants were asked to maintain the confidentiality of their own identity and the identity of other participants. Participants received up to US $50 as compensation. Data were deidentified before analysis.

Study Procedures

A total of 4 after-school sites located in Florida were randomly selected for recruitment. After approval from the program directors, a verbal announcement reached adolescents at these sites, and interested adolescents completed child assent and parental permission. For participation, adolescents needed to be aged 11 to 18 years (inclusive) and enrolled in a middle school or high school. Adolescents also needed to be comfortable using a computer and the internet.

During recruitment, adolescents and their parents were informed offline that the study aimed to improve adolescent health through an interactive program in Florida after-school sites; that the study may take approximately 2 months and 1 week; and that they will engage in activities, surveys, and interviews. The incentive was described to potential participants, and they were informed that participation is voluntary and confidential and that the data would be securely stored at the University of Florida. Recruitment and data collection took 3 months to complete.

Participants started their experience with the intervention 3 to 7 days after they completed the baseline survey. The statistical team generated the random allocation of sites to each condition. In ASPIRE and Storm-Heroes, participants used similar computers and had private classrooms for participation. A study team member was available for technical assistance and supervision. A volunteer site staff trained in youth engagement was present to ensure that participants did not deviate from the requested data collection procedures. Participants completed surveys in a supervised classroom setting immediately after the intervention and again 1.5 months later. Participants completed other survey assessments at follow-up (data not included in this paper).

Implementation of Each Intervention

Our study staff were trained to implement the program at the after-school sites. They traveled to each study site location to administer the ASPIRE and the Storm-Heroes programs. Participants were not told which intervention was of interest to the researchers. During the site visits, study staff recorded attendance, ensured that the appropriate regimen was implemented, and addressed any questions or concerns participants had during the sessions.

At each site designated to receive ASPIRE, adolescents engaged in five 1-hour sessions exclusively focused on the full ASPIRE program. This regimen was conducted similarly to previous work on ASPIRE. At each site designated to receive Storm-Heroes, participants were first organized into groups comprising 3 to 6 individuals, determined by the outcomes of the social network survey conducted at baseline. With the aid of the social network algorithm, the study team grouped each at-risk adolescent (those indicating the highest intention to use tobacco) with 2 to 5 of their closest peers exhibiting lower intention to use tobacco. Unexpectedly, it was observed that some participants were absent during certain sessions. As a result, the grouping was re-evaluated using the algorithm for the sessions when participants were absent. Within their groups, participants were instructed to engage in ASPIRE activities, followed by game-based social activities within the board game. The duration of board game play varied for each session depending on the length of the assigned ASPIRE activity.

Measures

We assessed the measures through web-based closed surveys in a classroom setting, and a study staff was available for assistance. Survey measures have been previously tested and validated. Multimedia Appendix 3 [34,37-47] includes a detailed description of the main measures, measure references, and Cronbach α values when applicable.

At baseline only, we included survey questions pertaining to potential confounders and demographic characteristics, including age, sex at birth, ethnicity, race, average grade at school, the number of detentions at school, parents' highest level of education, and perceived skills in playing board games. At baseline, we also measured the status of using vaping products, cigarettes, and cigars or little cigars using the Minnesota smoking index [37].

At both baseline and 1.5-month follow-up, we measured perceived risk of vaping, perceived risk of using conventional tobacco products (cigarettes, cigars, and little cigars), and tobacco knowledge [38,39] (Multimedia Appendix 3).

At immediate follow-up, we collected data regarding participants' experience with each of the programs using validated measures. First, to check for expected differences and similarities between the ASPIRE and the Storm-Heroes conditions, we assessed measures pertaining to key program features. We expected group differences with respect to perceived social interactivity [40] and group similarities with respect to attitude toward the program, visual esthetics, and emotional involvement [41-44]. Next, to assess engagement, we measured recognition of program imagery, attention to the program, and distraction from the program [45-47]. To capture user experience, we assessed participants' perceptions regarding the usability of the program [42,43], level of fun [41], narrative quality [42,43], program enjoyment [34], and creative freedom [42,43]. Considering the role of social interaction in the success of Storm-Heroes, we asked participants to indicate if they engaged in any discussions with their peers after the program. If they confirmed that they engaged in discussions, they were then asked to share the content of their discussion through an open-ended qualitative question. With a mixed methods approach, the qualitative responses were analyzed and coded to identify if participants discussed the program or tobacco (coded 1) or not (coded 0).

Statistical Analysis

We conducted statistical analyses using Stata (version 14; StataCorp LP). Considering cluster-randomization, we used multilevel generalized linear mixed effects models (GLMMs). For all GLMMs, we identified demographic characteristics that may need to be included in the models. In every GLMM, an after-school site was modeled as a random effect nested within the intervention condition, and the intervention condition and time (and their interaction) were modeled as fixed effects. GLMMs use maximum likelihood estimation, producing unbiased estimates when data are assumed to be not missing completely at random.

To conduct GLMMs using a target power of 0.85 and an effect size of 0.23 to perceived risk of vaping with an α value of .05, the estimated sample size was 45 participants [39]. We estimated that 75 adolescents would be needed to test the hypotheses, with an anticipated completion rate of approximately 60% (45/75). Considering the pilot nature of this study, this sample size was considered sufficient for the study of short-term secondary outcomes.

First, with GLMMs, we tested for any baseline differences between the 2 conditions with respect to demographic characteristics (eg, age, sex at birth, gender identity, grades at school, number of detentions, parental education level, and perceived skills playing board games). Second, with one-way ANOVA and chi-square tests, we examined attrition by testing differences between those retained and those lost to follow-up with respect to the outcome variables at baseline and other potential confounding factors.

Next, with GLMMs, we examined group differences for outcomes of interest. We conducted GLMMs predicting 5 types of outcomes. Manipulation check outcomes included perceived social interactivity, attitude toward the program, visual esthetics, and emotional involvement. Outcomes pertaining to participants' attention to the program included general attention, distraction from the program, and recognition of imagery from the program. Personal experience with the program included perceptions regarding program usability, level of fun, narrative quality in the program, program enjoyment, and creative freedom. Communication outcomes included engagement in discussions and quality of discussions. Tobacco-related outcomes included perceived risk of vaping, perceived risk of conventional tobacco use, and tobacco knowledge. Models predicting tobacco-related outcomes included group assignment, time, and the group-by-time interaction term as predictors. Following these models, we examined the role of attention to the program and personal experience factors in predicting tobacco-related outcomes.

For qualitative data, we conducted a thematic analysis of participants' responses to the open-ended question on engagement in discussion. We aimed to look for themes pertaining to tobacco, the program, or both. Next, we generated a binary variable that indicates if participants positively discussed tobacco or the program.

Results

Participants

In terms of demographics, the average age of the participants was 13.55 (SD 1.65) years, with 5% (40/74) of the participants aged ≤13 years, 58% (43/74) being female at birth, and most (56/72, 78%) being Black or African American. Approximately 37% (26/70) of the participants reported having at least 1 friend who vapes, and approximately 13% (9/69) of the participants reported having at least 1 friend who smokes a combustible product. Table 3 presents the demographic characteristics by group.

Table 3. Baseline participants' characteristics.

Characteristics	Total sample (N=74)	Storm-Heroes (n=39)	ASPIRE[a] (n=35)	*P* value
Age (y), n (%)				.96[b]
≤13	40 (56)	19 (49)	21 (64)

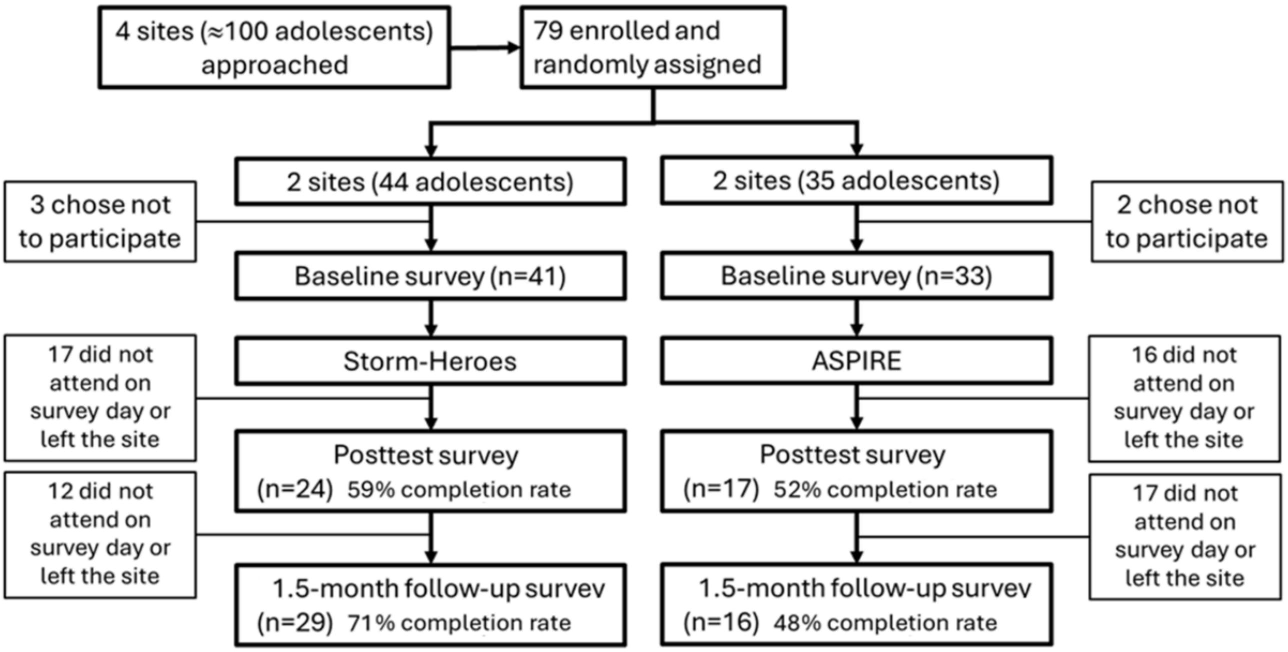
[c]Significance testing with mixed effect regression to adjust for group randomization (continuous variables).

Attrition

No harm or unintended effects occurred in this study. In this study, >100 adolescents expressed interest, and 79 enrolled, with the 4 sites randomly assigned to either Storm-Heroes or ASPIRE. In total, 94% (74/79) of the adolescents completed the baseline survey. Among baseline participants, 55% (41/74) participated in the posttest experience survey and 61% (45/74) participated in the 1.5-month follow-up survey (Figure 2). Participants who did not complete surveys had left the after-school site or did not attend the site on the day of data collection.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. Participants were allowed to participate in any survey assessment over time. ASPIRE: A Smoking Prevention Interactive Experience.



Participants in Storm-Heroes were as likely to continue to follow-up assessment as those in ASPIRE (χ^2_1=3.2; *P*=.07). There were no significant differences between participants who did and those who did not continue to the 1.5-month follow-up with respect to baseline perceived risk of vaping ($F_{1,73}$=3.74; *P*=.06), perceived risk of conventional tobacco use ($F_{1,73}$=2.43; *P*=.12), tobacco knowledge ($F_{1,58}$=2.40; *P*=.13), sex at birth (χ^2_1=0.5; *P*=.50), age ($F_{1,76}$=0.94; *P*=.34), being Black or African American (χ^2_1=2.2; *P*=.14), being Hispanic or Latinx (χ^2_1=0.1; *P*=.75), grades at school (χ^2_1=0.6; *P*=.44), parents' level of education (χ^2_1=0.2; *P*=.34), the number of friends who vape ($F_{1,68}$=0.59; *P*=.44), the number of friends who smoke ($F_{1,67}$=2.92; *P*=.09), or perceived skills in playing board games ($F_{1,70}$=0.57; *P*=.45). These data are further detailed in Multimedia Appendix 4.

Manipulation Checks

We checked to ensure that participants expressed positive attitudes toward both interventions equally. There was no significant difference between the 2 conditions with respect to attitude scores (B=0.76; *P*=.07) or visual esthetics of the program (B=1.28; *P*=.14). With both interventions being entertainment based, there was no significant difference between the conditions with respect to being emotionally involved in the content (B=0.31; *P*=.56). As expected, participants who received Storm-Heroes perceived the program to be more socially interactive than those who received ASPIRE (B=5.33; *P*=.02).

Checking for Confounders

We tested potential confounding effects of demographic characteristics. There were no significant differential effects on perceived risk of vaping as a function of perceived board game skills, race, or the number of detentions. Being younger (*P*<.001), being male (*P*=.001), being non-Hispanic (*P*=.02), having friends who vape (*P*=.001), having friends who smoke (*P*<.001), and having parents with lower education level (*P*=.04) moderated the effect of Storm-Heroes on perceived risk of vaping.

There were no significant differential effects on perceived risk of conventional tobacco use as a function of age, perceived board game skills, ethnicity, race, and number of detentions. Being male (*P*<.001), having friends who vape (*P*<.001), having friends who smoke (*P*<.001), and having parents with lower education level (*P*=.04) moderated the effect of Storm-Heroes on perceived risk of conventional tobacco use.

There were no significant differential effects on tobacco knowledge as a function of age, ethnicity, race, or the number of detentions. Having lower boardgame skills (*P*<.001), being female (*P*=.001), being non-Hispanic (*P*<.001), having friends who vape (*P*<.001), having friends who smoke (*P*=.01), and having parents with lower education level (*P*<.001) moderated the effect of Storm-Heroes on tobacco knowledge.

Personal Experience

Mixed effects models controlling for confounders showed that participants who received Storm-Heroes were significantly more likely to be distracted during the program (B=1.36; *P*=.002) and less likely to recognize images from the program (B=1.68; *P*<.001). However, they were more likely to pay attention to the program than those who received ASPIRE (B=1.30; *P*=.02). By examining the interaction between intervention groups and distraction, we found that distraction weakened the effect of Storm-Heroes on recognition of program imagery (B=–0.49; *P*=.005).

Participants who received Storm-Heroes found the program to have significantly better usability (B=0.88; *P*=.001), higher level of fun (B=4.14; *P*=.001), better narrative quality (B=2.66; *P*=.001), more enjoyment (B=2.16; *P*=.047), and more creative freedom (B=1.90; *P*=.047) than participants who received ASPIRE.

Communication Outcomes

Participants who received Storm-Heroes were significantly more likely to talk to others during the program (odds ratio [OR] 4.99, 95% CI 1.04-23.85; *P*=.04). They also experienced a better quality of peer-to-peer discussions (B=2.16; *P*=.047). According to the open-ended questions about the content of their discussions, participants who received Storm-Heroes were significantly more likely to discuss the program and the negative effects of tobacco with their peers than those who received ASPIRE (OR 5.63, 95% CI 1.25-25.29; *P*=.02). By examining the role of social interactivity, it was found that participants who found the program to be socially interactive were approximately twice as likely to talk about the program and the negative effects of tobacco (OR 1.98, 95% CI 1.28-3.07; *P*=.002).

Tobacco-Related Outcomes

Mixed effects models indicated that group allocation by time was significantly related to perceived risk of vaping (group-by-time: B=0.35; *P*=.001; Figure 3A). Participants who received Storm-Heroes were significantly more likely to exhibit a higher perceived risk of vaping at follow-up than participants who received ASPIRE, controlling for perceived risk of vaping at baseline (B=0.40; *P*=.02; Table 4).

Figure 3. Adjusted predictions of condition-by-time. Coefficients and *P* values show significance of the group-by-time interaction effect. Perceived risk measures can range between 1 and 4, while tobacco knowledge can range between 0 and 22. ASPIRE: A Smoking Prevention Interactive Experience.

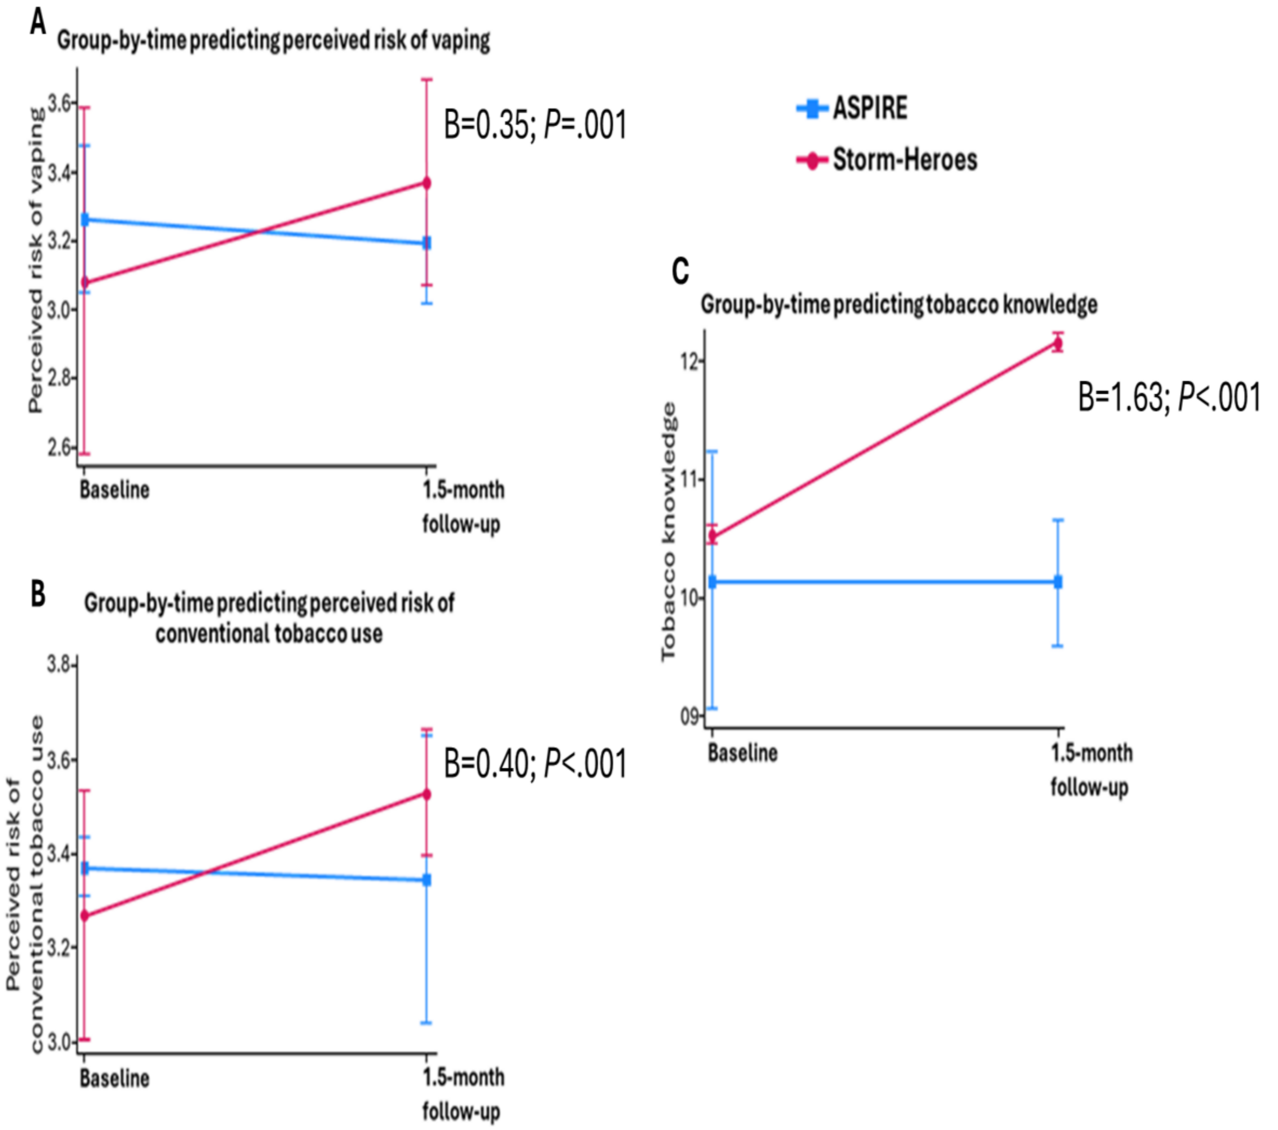


Table 4. Multilevel models predicting the perceived risk and tobacco knowledge.

	Model 1: predicting the perceived risk of vaping at follow-up (n=42)		Model 2: predicting the perceived risk of conventional tobacco use at follow-up (n=42)		Model 3: predicting tobacco knowledge at follow-up (n=19)	
	B (SE)	*P* value	B (SE)	*P* value	B (SE)	*P* value
Receiving Storm-Heroes	0.40 (0.17)	.02	0.35 (0.18)	.046	1.75 (0.56)	.002
Perceived risk of vaping at baseline	0.60 (0.17)	<.001	—[a]	—	—	—
Perceived risk of conventional tobacco use at baseline	—	—	0.68 (0.19)	<.001	—	—
Tobacco knowledge at baseline	—	—	—	—	0.53 (0.21)	.01
Number of detentions	–0.44 (0.31)	.16	–0.28 (0.15)	.06	—	—
Average grades at school	—	—	—	—	0.93 (0.21)	<.001
Parents' level of education	—	—	—	—	0.76 (1.84)	.68

[a]Not available; the models were fitted based on identified key covariates.

Participants in the Storm-Heroes condition were significantly more likely to exhibit an increase in perceived risk of conventional tobacco than participants in the ASPIRE condition (group-by-time: B=0.40; *P*<.001; Figure 3B). Participants in the Storm-Heroes condition were significantly more likely to exhibit higher perceived risk of conventional tobacco use at follow-up than participants in the ASPIRE condition, controlling for perceived risk of conventional tobacco at baseline (B=0.35; *P*=.046; Table 4).

Participants in the Storm-Heroes condition were significantly more likely to exhibit an increase in tobacco knowledge than participants in the ASPIRE condition (group-by-time: B=1.63; *P*<.001; Figure 3C). Participants in the Storm-Heroes condition were significantly more likely to exhibit higher tobacco knowledge at follow-up than participants in the ASPIRE condition, controlling for tobacco knowledge at baseline (B=0.53; *P*=.01; Table 4).

Experience Factors Predicting Tobacco-Related Outcomes

Controlling for group allocation, the results showed that the usability level of the program was related to a higher perceived risk of vaping (B=0.16; *P*=.003) and conventional tobacco use (B=0.16; *P*=.02) by follow-up. Attention to the program was also related to higher perceived risk of vaping (B=0.12; *P*=.002) and conventional tobacco (B=0.14; *P*<.001). Distraction was not related to either perceived risk of vaping (*P*=.15) or perceived risk of conventional tobacco use (*P*=.71). In contrast, both more attention (B=0.60; *P*<.001) and less distraction (B=–0.37; *P*<.001) were related to higher tobacco knowledge. A follow-up exploratory analysis of moderation indicated that distraction weakened the effect of receiving Storm-Heroes on tobacco knowledge by follow-up (group-by-distraction: B=–6.67; *P*<.001).

Discussion

Principal Findings and Comparison to Prior Work

This paper describes a pilot cluster-randomized comparative trial examining the short-term effectiveness of Storm-Heroes, a social game–based intervention, in improving secondary tobacco-related outcomes, including perceived risk of tobacco use and tobacco knowledge. The paper also presents results from adolescents' experience with the intervention and its prediction of such outcomes. We hypothesized that adolescents' engagement with Storm-Heroes would result in (1) better quality of program experience; (2) improved perceived risk of vaping and conventional tobacco use; and (3) improved tobacco knowledge compared with the engagement in ASPIRE, a nonsocial, non–game-based equivalent program.

The increased perceived risk of vaping and conventional tobacco among Storm-Heroes participants aligns with the program's goals of improving participants' awareness of the risks associated with tobacco use. With antitobacco messages designed to communicate tobacco risk, Storm-Heroes may have effectively presented the severity of tobacco-related harm. The comprehensive content in Storm-Heroes is designed with key risk communication strategies, including emotionally involving gain-framed and loss-framed messages that cover the psychological, physiological, medical, and environmental consequences of tobacco use [25]. In addition, along with other theoretical frameworks, the program design is grounded in the health belief model and empowerment theory, promoting perceived susceptibility [48] and self-efficacy [49,50]. The game-based social activities in Storm-Heroes allow adolescents to engage in interactive learning experiences that empower them to recognize and internalize the harms of tobacco, motivating them toward tobacco-free lifestyles [21].

The Storm-Heroes group showed a significant increase in tobacco knowledge scores from baseline to 1.5-month follow-up. Knowledge gained among Storm-Heroes participants compared to ASPIRE participants may be the outcome of both exposure to information within the program and increased motivation to seek information elsewhere (eg, from school teachers, the internet, etc). First, by integrating multimedia resources and a proactive learning approach, Storm-Heroes aimed to equip adolescents with comprehensive knowledge. As supported by previous research [25], the program's tobacco education content was carefully designed to cover several key topics (Multimedia

Appendix 1) and promote a holistic understanding of information from a wide array of tobacco products [25]. In addition, the gameplay aspect of Storm-Heroes encourages structured information retention that can support knowledge gain. Second, gameplay and other entertainment-based programming have been shown to stimulate interest in understanding health issues and ultimately promote health information seeking beyond the content of a program [12,51,52]. This information-seeking behavior may ultimately contribute to increased knowledge. In addition to the tobacco-related outcomes, we identified user experience differences between the 2 programs.

In the context of program experience, our results indicate that participants expressed similar positive attitudes toward both programs, with no significant difference in attitude scores or perceived visual esthetics. Emotional involvement in the content was also similar between the 2 groups. However, Storm-Heroes was perceived as more socially interactive than ASPIRE. Supportive of previous research, the similar attitude toward both interventions suggests that entertainment-based approaches, regardless of social interactivity, can effectively engage adolescents. However, Storm-Heroes was perceived as more socially interactive than ASPIRE, which aligns with previous findings indicating that interactive elements enhance program appeal [21,53,54]. As supported by the social learning theory and a systematic review of tobacco education programs, incorporating social features into interventions can promote health behavior change by fostering a sense of peer support for adolescents [55]. Our results suggest that while entertainment-based approaches effectively engage adolescents, perceived social interactivity of Storm-Heroes may play a unique role in its success.

Our results further indicated that participants in the Storm-Heroes program were more likely to engage in conversations with others during the program and experienced better-quality peer-to-peer discussions compared to those in the ASPIRE program. They were more likely to discuss the program and the harm of tobacco use. This suggests that Storm-Heroes may have included strategies that successfully encourage healthy dialogues among participants. Theoretical frameworks such as the extended elaboration likelihood model [56] support the ability of entertainment-based programming to promote healthy interpersonal discussions. This has been particularly evident when it comes to sensitive health topics such as contraceptive use, organ donation, and underage tobacco use [52,57-59]. Our results show that participants who found the program to be socially interactive were more likely to engage in healthy discussions. In line with the social learning theory, social interaction can facilitate social modeling and promote healthy learning [60,61]. Future research could further investigate the mechanisms that allow Storm-Heroes to drive these communication outcomes.

Participants who received Storm-Heroes were more likely to be distracted during the program and less likely to recall images from it. Nevertheless, they were more attentive overall compared to ASPIRE recipients. While Storm-Heroes led to more distractions and lower image recall, its higher attention levels imply deeper engagement despite potential distractions. However, the challenge lies in balancing engagement with lower distractions, as distractions may undermine the program's effectiveness. While distraction did not significantly impact perceived risk of vaping or conventional tobacco use, it was negatively associated with tobacco knowledge, thereby hindering adolescents' learning and retention of information. Future research should focus on implementation strategies to minimize distraction for Storm-Heroes. For example, using a flipped classroom approach can allow adolescents to receive tobacco-related information at home through entertaining videos and engage in social activities in class to practice what they learned [62]. This implementation strategy can reduce cognitive load, thereby optimizing engagement without compromising health education [63].

The findings support the original mechanisms of action outlined in Table 2. The significant increase in attention among participants who received Storm-Heroes highlights the effectiveness of using engaging and interactive elements such as gameplay and social interaction. Despite an increase in distraction and a lower recognition of program imagery, participants who received Storm-Heroes reported higher levels of usability, fun, narrative quality, enjoyment, and creative freedom compared to those who received ASPIRE. These factors likely contributed to enhanced perceived risk and knowledge, as suggested by the mechanisms of action. The enjoyment and narrative quality could have facilitated social interactions and discussions about tobacco, while the creative freedom and program interactivity bolstered participants' engagement and practice of tobacco-free skills. Although distraction diminished the program's impact on recognizing program imagery, the overall roles of positive reception and attention underscore the potential of Storm-Heroes to effectively leverage the social learning theory and the health belief model to promote tobacco prevention among adolescents. Considering the pilot nature of this study, we invite researchers in games for health to further explore these mechanisms.

This study advances our understanding of how game-based approaches that leverage social elements can be strategically applied to address adolescent tobacco use. While existing research has highlighted the potential role of personal engagement in games in driving health outcomes [20,64], this study distinguishes itself by focusing on social gameplay. The study specifically examines the comparative effectiveness of a socially interactive game versus a nonsocial program. By integrating social interactivity with tobacco prevention strategies, the research provides new insights into how interactive elements can enhance engagement and improve outcomes such as tobacco knowledge and perceived risks.

Unlike previous studies [26,65], which have broadly addressed game-based learning, our study delves into the unique role of multiplayer gameplay and its impact on adolescent tobacco prevention. The findings underscore the unique role of social games in fostering meaningful peer-to-peer discussions and elevating tobacco risk awareness among adolescents. Moreover, while previous research highlighted the need to boost engagement by lowering the negative effect of social influence [26,65], this study demonstrates that multiplayer gameplay can be affected by distractions, and minimizing these distractions can optimize the educational impact of social games.

Limitations

First, this study ended with a relatively low retention rate (45/74, 61%). By the time this study reached 1.5-month follow-up, adolescents were at a transition out of the after-school summer period, entering the fall semester, and ultimately, several of them were not available to continue in the study. In addition, several participants had to leave early during the data collection at the 1.5-month follow-up, which led to a low sample of participants who completed the knowledge index. This low retention rate could have influenced the study's results by reducing the generalizability and statistical power. While our use of repeated measures mixed effects modeling allowed us to account for missing data, future studies could mitigate this limitation by planning data collection at more stable periods, such as during school class sessions, and by enrolling a larger initial sample size to account for potential dropouts.

Second, although this study showed a change in short-term outcomes (ie, tobacco risk perception and knowledge), we did not examine a long-term change in tobacco use behavior. It must be noted, though, that this early pilot trial was meant to test the potential for adolescents' experience with Strom-Heroes to drive risk perception and knowledge. The lack of long-term behavioral data may limit the ability to draw conclusions about the program's effectiveness in reducing actual tobacco use over time. To address this, future research should include longer follow-up periods and assess behavioral outcomes to provide a more comprehensive evaluation of the program's impact.

Third, this study did not examine the specific types of discussions adolescents engaged in during their interactions. Without a detailed analysis of the content of these discussions, it is not possible to investigate how the program influences communication behaviors or the outcomes of these discussions. Future studies could enhance the research by incorporating qualitative methods, such as focus groups or interviews, to explore the content and context of these discussions, thereby providing deeper insights into the program's impact on social interactions.

Fourth, from an implementation perspective, the study required staff members to deliver the program to each classroom and moderate the sessions. This approach may limit the program's scalability and dissemination potential. The reliance on staff for program delivery could also introduce variability in implementation quality. To improve this, future efforts should consider adapting the procedures to allow teachers to deliver the program. This would not only facilitate broader reach but also create a more sustainable implementation model. Using Proctor's Framework for Implementation Outcomes, future studies could evaluate the program by assessing teachers' adherence to key steps, the quality of their engagement, their satisfaction, and the perceived feasibility of the program.

Implications

The results of this study suggest that Storm-Heroes can be a promising intervention for tobacco prevention. Nevertheless, we must further examine strategies that may allow us to minimize distractions while maximizing engagement to boost the success of this intervention. Once the design of this program is clear, it becomes possible to further investigate its success by examining its long-term effects on actual tobacco use. In addition, promoting peer-to-peer interactions can improve the impact of such interventions by facilitating knowledge dissemination and perceived tobacco risks. In the long run, going beyond these short-term outcomes, randomized trials with longitudinal data collection can provide valuable insights into the success of Storm-Heroes in preventing actual initiation of tobacco use and identify the factors that may promote long-term prevention outcomes. Future researchers can work to identify the specific program components and delivery methods that contribute to enhancing adolescents' experience and improving tobacco-related outcomes. In addition, by identifying effective components responsible for an improved program experience, we can design novel interventions that can be tailored to target specific groups of adolescents and address their unique needs concerning different tobacco products.

Abstract

Background: In recent years, the integration of technology in education has revolutionized traditional learning paradigms. Digital literacy, a crucial skill in the 21st century, has become a vital aspect of modern education, enabling students to navigate, critically assess, and effectively use digital tools. As educators strive to boost engagement and learning outcomes, gamification has appeared as an auspicious pedagogical approach. By applying game mechanics to nongame contexts, gamification seeks to create a more immersive and digital learning experience.

Objective: This research paper aims to investigate the impact and acceptance of gamification by learners in a digital literacy course at the undergraduate level.

Methods: In a pre-post intervention study, 168 undergraduate students were randomly assigned either to the experimental group (gamification based) or control group (conventional) learning condition. Both groups of participants learned the same topics in digital literacy.

Results: Empirical findings showed that participants from the experimental group had better academic performance in digital literacy than those who were not exposed to the game-based learning environment. The participants' prior experience with gamification was not found to be a significant predictor of their acceptance of gamification in a digital literacy course.

Conclusions: The study provides evidence supporting the potential benefits of gamification in enhancing digital literacy education and opens the door for further exploration and implementation of gamified learning approaches in higher education settings.

KEYWORDS

gamification; games; technology integration; information literacy; technology acceptance

Introduction

Background

In today's interconnected world, the demand for digital literacy has intensified across academic, professional, and personal domains. Digital literacy is a set of skills essential for 21st century individuals to use digital tools to support the achievement of goals in their life situations [1,2]. It has become not only a key factor in enabling participation in education and employment but also a means of interacting with the world. It encompasses the ability to access, analyze, evaluate, and create information using various digital applications. In the context of undergraduate education, cultivating digital literacy is essential for students to excel in their studies, conduct research, and adapt to the demands of the workforce in the information era. As universities strive to equip their students with these vital skills, innovative teaching approaches that enhance engagement and knowledge retention are warranted [3].

At the same time, incorporating gamification into pedagogical approaches has gained considerable attention [4,5]. The term gamification first appeared in 2008 and received growing significance since the 2010s [6]. In general, gamification refers to a process of augmenting services with (motivational) affordances to raise gameful experiences and promote behavioral outcomes [7]. In contrast to games, gamification is described by its serious purpose. It involves applying game design elements and mechanics in nongame contexts to enhance user engagement, motivation, and learning outcomes. According to Trinidad et al [8], gamification has swiftly appeared as one of the preferred persuasive technologies widely used with the aim of stimulating a positive change in the user's behavior through game-like elements in nongame contexts. Likewise, Krath et al [6] argued that gamification is a great way to demonstrate goals and their germaneness, push users through directed tracks, provide users instant feedback, strengthen good performance, and streamline content to manageable tasks. It leverages the intrinsic motivational elements found in games to create a positive and engaging learning environment. Hamari et al [7] suggest that gamification has beneficial impacts; however, these effects greatly rely on the context in which it is used as well as on the individuals who practice it. Similar to this, Huang et al [9] argue that it can be difficult for educational academics and practitioners to decide when and how to apply gamification design elements.

Given the significant traction gained by gamification in recent years, several state-of-the-art gamified solutions and approaches have been developed and tested [10]. One widely used example of gamification for education is Kahoot. Kahoot! is a game-based learning platform that allows educators to create and deliver quizzes in a game format [11]. It incorporates leaderboards, points, and real-time feedback to create a competitive and engaging learning environment. Research indicates that Kahoot! enhances student participation and knowledge retention [12]. Similarly, Duolingo is a language-learning platform that uses gamification to teach foreign languages. It uses elements such as skill trees, streaks, and in-game currency to motivate learners. Studies have found that Duolingo is effective in improving language proficiency and maintaining learner interest [13].

Gamification is significantly correlated with game-based learning. Game-based learning is defined as the achievement of distinct learning objectives through game content and play and augmenting learning by including problem-solving spaces and challenges that offer learners, who are also players, with a feeling of achievement [6]. By incorporating game design elements such as points, badges, levels, leaderboards, and immediate feedback, gamified learning experiences can stimulate students' curiosity and foster a sense of accomplishment [5,14]. Through gamification, educators aim to increase student motivation, participation, and knowledge retention by transforming learning from a passive experience into an active and enjoyable process [15,16]. Hamari and Homner have also recognized it as a promising method for instructional contexts for its motivational power [7]. The application of gamification has been successful in various educational contexts [9], including language learning [17,18], mathematics [19,20], and computer programming [21]. Its use in nongame contexts is associated with impacts on motivation, behavior (eg, academic achievement and engagement), and cognitive learning [6]. All of this demonstrates the potential of gamification to augment a digital literacy learning experience as well.

Even though recent research has made significant strides in this area, additional information about the integration of game aspects into educational materials is still required. Particularly, there is a dearth of coherent understanding on its use in the subject area of digital literacy. Particularly, there is a need to explore how adult learners perceive and accept gamification in the context of a digital literacy course at the undergraduate level in Saudi Arabia. By investigating the impact and acceptance of gamification in a digital literacy course at the undergraduate level, this research aims to shed light on its efficacy and potential for cultivating essential digital literacy. Addressing this gap in knowledge will provide valuable insights into the factors that influence Saudi students' acceptance of gamification and the impact it has on their learning experience, thereby enabling educators and course designers to make informed decisions regarding the effective implementation of gamification strategies.

In the next section, we discuss the theoretical foundations for this study that helped us formulate our research questions and hypotheses.

Theoretical Framework

In recent years, scientific papers have progressively investigated the use of different theoretical foundations such as motivation, behavior, and learning theories to explain the effects of certain gamification elements [6]. The theoretical footings of this study align with 2 pronounced frameworks in the field of education and technology: the self-determination theory (SDT) and the technology acceptance model (TAM). These theoretical foundations provide a comprehensive lens through which to understand the impact and acceptance of gamification in the context of digital literacy education at the undergraduate level. A brief overview of these theories and justification how they are aligned with this study is provided in the following sections.

Self-Determination Theory

Developed by Deci and Ryan, the SDT posits that individuals have innate psychological needs for autonomy, competence, and relatedness, which serve as essential motivators for behavior and engagement [22]. In the context of education, SDT suggests that learners are more likely to be intrinsically motivated and experience greater satisfaction and well-being when their psychological needs for autonomy, competence, and relatedness are supported [22].

The integration of gamification in educational settings can be viewed through the lens of the SDT, as it has the potential to fulfill learners' psychological needs helping them experience intrinsic motivation, which drives them to engage in activities for the sheer enjoyment and interest in the task itself [22]. By providing learners with autonomy through choice and control over their learning paths, gamified experiences empower students to take ownership of their learning. Further, the challenge-based nature of game-based experiences foster feelings of competence as learners strive to achieve goals and overcome obstacles within the game environment. In addition, the social elements inherent in many gamified platforms facilitate a sense of relatedness by promoting collaboration, competition, and community among learners [6].

SDT is one of the well-known theories in the context of gamification. In the context of this study, the impact of gamification on learning outcomes can be better understood in terms of its alignment with the principles of SDT. Accordingly, by leveraging game mechanics to enhance autonomy, competence, and relatedness, gamification has the potential to promote intrinsic motivation and engagement [7] among undergraduate students in a digital literacy course.

Technology Acceptance Model

A popular framework for evaluating people's attitudes and behavioral intentions toward embracing new technologies is Davis's TAM [23]. According to TAM, perceived usefulness and perceived ease of use are key determinants of any individual's intention to use a technology, which eventually influences his or her actual usage behavior. Perceived usefulness refers to the extent to which a person believes that using a particular technology will enhance their performance or productivity, while perceived ease of use pertains to the degree of effort required to use the technology effectively [24].

TAM has been extensively used in the context of educational technology to examine learners' attitudes and behaviors toward various digital tools and platforms. Researchers can learn more about the elements influencing students' acceptance and engagement with these technologies by evaluating how useful and simple they believe gamified learning environments to be [24,25]. In this study, TAM provides a theoretical framework for understanding learners' acceptance of gamification in a digital literacy course. By investigating the perceived usefulness and ease of use of gamified learning experiences, the study seeks to elucidate the factors that contribute to students' willingness to engage with and embrace gamification as a pedagogical approach.

By integrating the SDT and TAM frameworks into the research design and analysis, this study aims to provide a comprehensive understanding of the impact and acceptance of gamification by learners in a digital literacy course at the undergraduate level. In aligning our research design with the constructs of SDT, we focused on measuring students' intrinsic motivation and perceived autonomy in the learning process. Similarly, the TAM informed our analysis of students' acceptance of gamified learning tools, focusing on perceived ease of use and usefulness as key determinants. Furthermore, in interpreting our findings, we draw on both frameworks to discuss theoretical and practical implications of the study.

Research Gap and Rationale

The growing significance of digital literacy in the modern world necessitates effective and engaging teaching strategies. Gamification has arisen as an encouraging approach that leverages the power of games to enhance learning experiences. While gamification shows promise as an innovative pedagogical approach, its impact and acceptance specifically in the context of digital literacy courses at the undergraduate level remain relatively unexplored. Existing research primarily focuses on the effects of gamification in K-12 education or specialized domains [6,26,27]. For example, Dehghanzadeh et al [25] concentrated on gamification-supported learning in K-12 settings, and Tan et al [27] described several mathematics gamification instances to enrich algebra teaching at school levels. Thus, there is a need to delve into the unique challenges and opportunities of implementing gamification in higher education, particularly in digital literacy courses. By investigating the impact of gamification on learning outcomes, the study can offer insights into the effectiveness of this approach in improving digital literacy among undergraduate students. Moreover, understanding students' perceptions and acceptance of gamification can provide crucial feedback for educators and instructional designers to refine gamified learning experiences in digital literacy courses. The study's outcomes may also inform policy decisions regarding the integration of gamification and technology in higher education curricula, paving the way for more engaging and effective teaching practices in the digital age.

Research Questions

This study seeks to contribute to the existing body of knowledge by examining the following research questions:

1. What is the impact of gamification on the learning outcomes of students in a digital literacy course at the undergraduate level?
2. What factors affect the acceptance of learners toward gamified learning experiences in a digital literacy course?
3. How does learners' prior experience with gamified learning environments affect their acceptance of gamification in a digital literacy course at the undergraduate level?

Based on the above research questions, the following hypotheses are proposed:

- H1: Gamification has a significant positive effect on learning outcomes of students in a digital literacy course at the undergraduate level.
- H2: Age and the major of students' degree programs are significant factors influencing learners' acceptance of gamification in a digital literacy class.
- H3: Learners' prior experience with gamified learning environments has a significant effect on their acceptance of gamification in a digital literacy course.

Methods

Participants

Using convenience sampling, this study involved a diverse group of 168 undergraduate students enrolled in a digital literacy course at a Saudi university. While convenience sampling may not provide a representative sample of the population, it is the most practical in small-scale studies or when studying hard-to-reach populations [28]. Likewise, this study justifies this approach by emphasizing the need to assess the initial impact of a specific pedagogical approach in a real-world setting before considering broader applications or generalizations. All of these participants were native Arabic speakers. The students' age ranged from 18 to 22 years with an average of 20.6 years.

Intervention students participated in the 16-week digital literacy course. The course is offered to the students enrolled in various undergraduate programs. The participants were distributed into 2 groups for a true experimental design [29,30]. There were 84 students in the experimental group and 84 in the control group. Participants in this study were randomly assigned to either the control group or the experimental group using a computerized randomization procedure.

The process of randomization of the participants into the 2 groups started with the creation of a list of all participating students, including their names and class roll numbers. A random number generator was used to create a sequence of random numbers corresponding to the total number of participants (N=168). This sequence was generated using a computer software program designed for randomization to eliminate any potential bias. The first 84 numbers in the sequence were assigned to the experimental group, and the remaining 84 numbers were assigned to the control group. The allocation process was conducted by a researcher who was not involved in the instructional process to ensure blinding. This helped minimize any potential bias in group assignment. This approach ensured that each participant had an equal chance of being placed in either group, thereby minimizing potential biases and confounding variables. By implementing random assignment, the study aimed to create comparable groups, ensuring that any observed differences in digital literacy skills and engagement could be attributed to the gamified intervention rather than to pre-existing differences between the participants.

Experiment Process

The teaching process took place partially in a lecture room and a computer lab. The duration of each lesson was 1 hour. The whole experiment lasted for 16 weeks. In order to ensure that participants in the experimental (game-based) and control groups (nongame based or conventional) had the same knowledge, participants in both groups were asked to appear in a pretest. All the participants in both groups received teaching through conventional teaching methods until week 10 of the semester. However, the experimental and control groups were taught using 2 diverse teaching methods over the next 6 weeks (weeks 11 - 16). During these 6 weeks, the participants in the experimental group experienced gamification to facilitate their learning of the topics taught during this period (see Figure 1 and Figure 2 to view the snapshots of one of the games used to teach cybersecurity), while the participants in the control group continued their learning of the same topics through conventional teaching methods.

After the 16-week teaching-learning process, both groups took an achievement test for the full term with some questions dedicated to assessing the topics covered in weeks 11-16 (the intervention time when the 2 groups of participants were taught using different teaching strategies, ie, game based and conventional). At the same time, a survey questionnaire was administered in the experimental group to assess their acceptability of gamification to support their learning in a digital literacy course (see Figure 3 for the graphical flow of the experimental process of this study). The study was authorized by the ethics committee of the corresponding author's university. All the participants provided written informed consent before their participation in the study, and they did not receive any monetary or other sort of compensation.

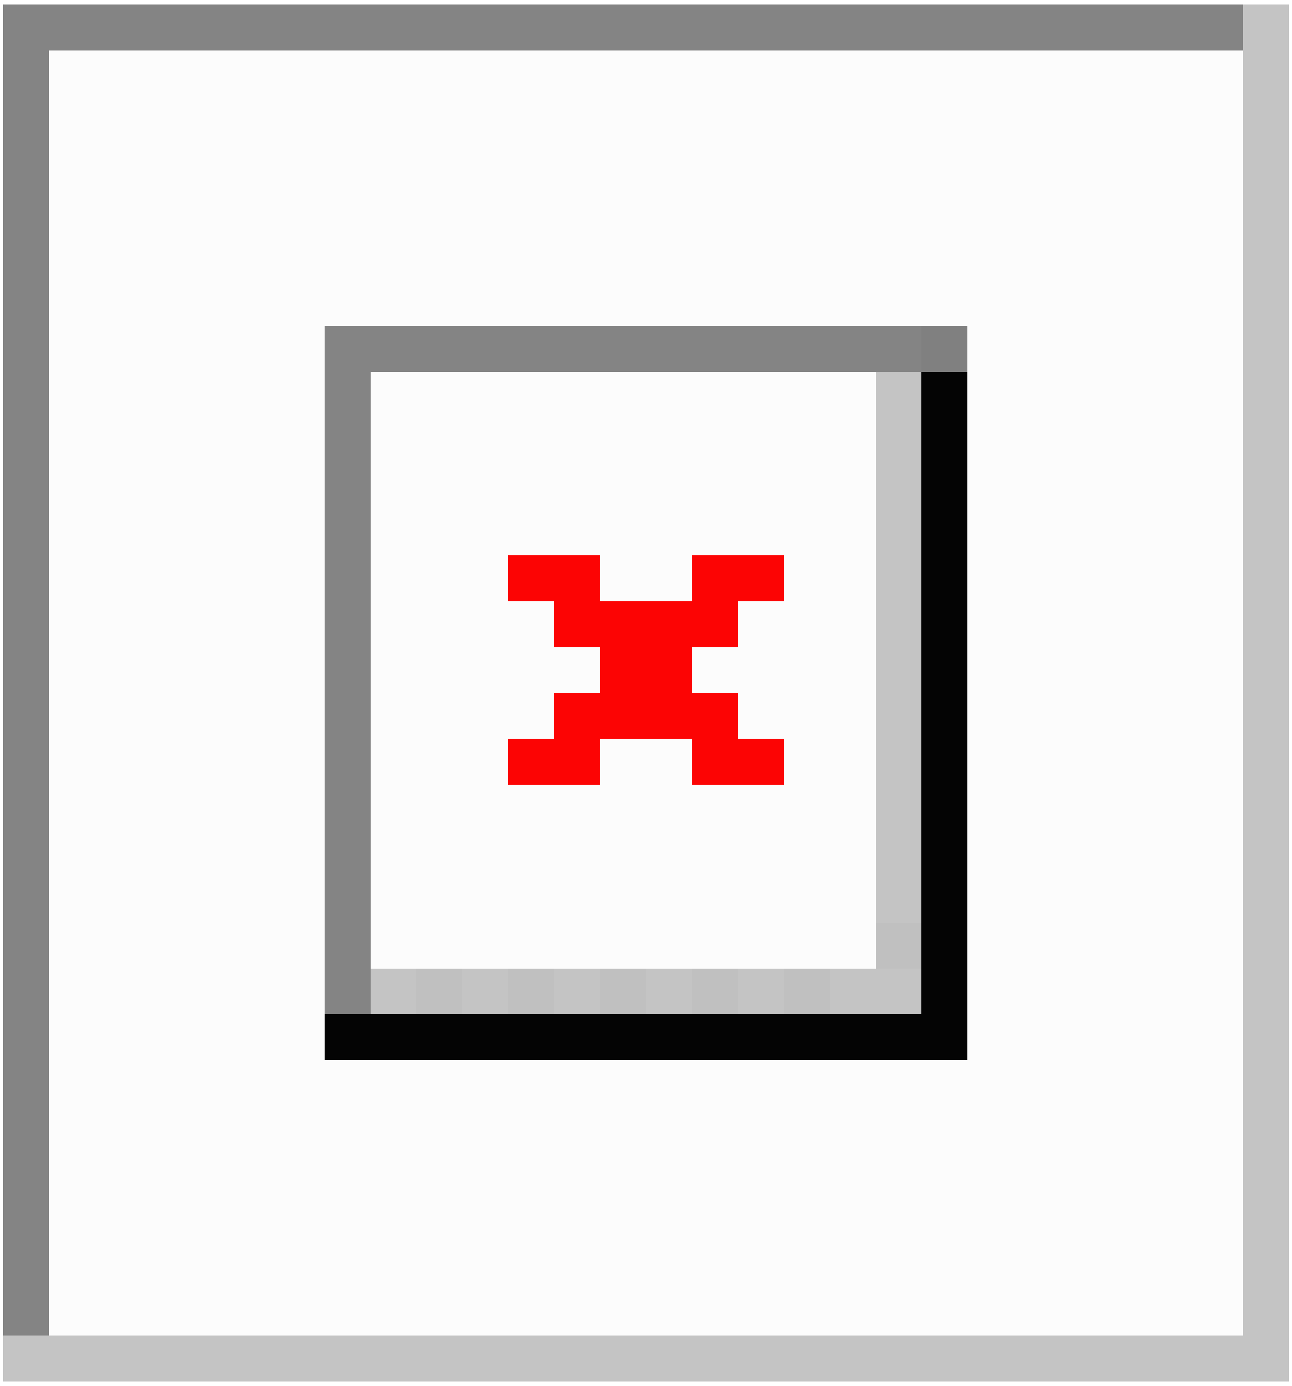

Figure 3. Experiment process.

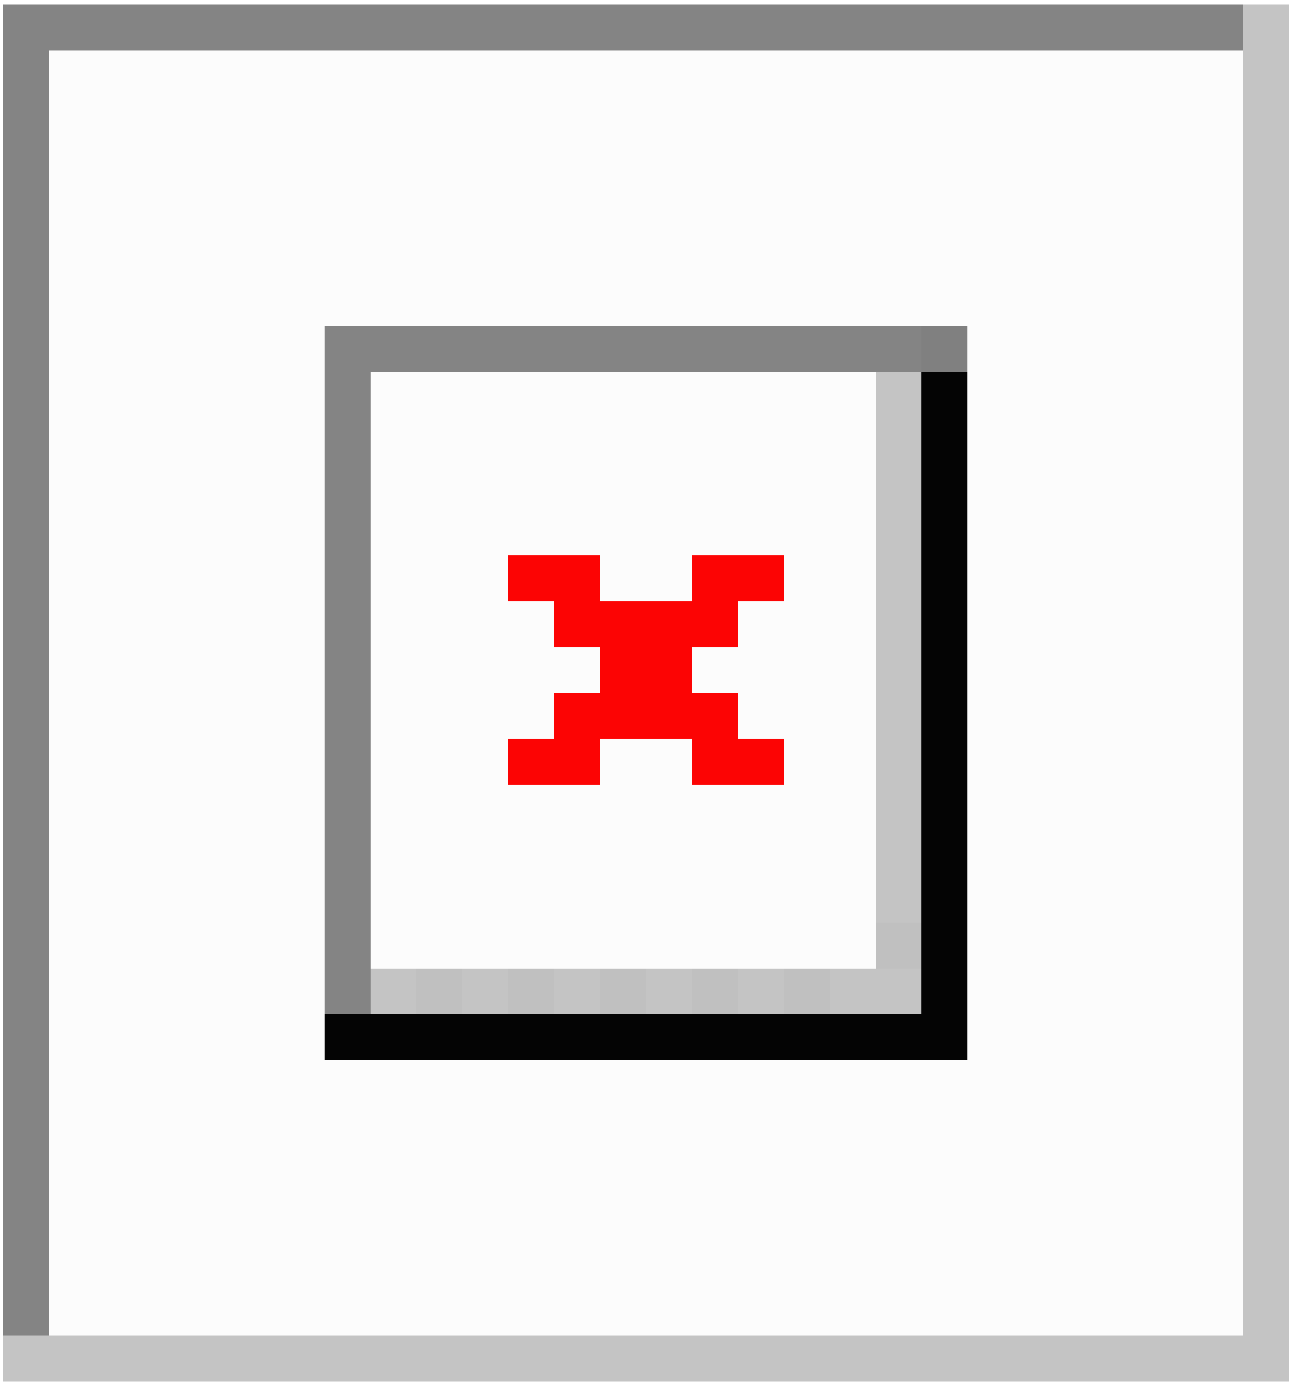

Game Application and Elements

The experimental group was introduced to NOVA Labs, a digital platform that engages learners in games and interactives that foster authentic scientific exploration. This platform incorporated several gamification elements to enhance students' engagement and motivation:

1. Points system: Each task or activity within the course was assigned a point value. Students accumulated points for every completed activity, which contributed to their overall score and ranking on the leaderboard.
2. Badges: Students could earn badges for completing various tasks and reaching milestones. For instance, badges were awarded for completing weekly assignments on time, achieving high scores on quizzes, and participating in group discussions and collaborative projects.
3. Leaderboards: A dynamic leaderboard was displayed within the application, showcasing the top performers in the class. This element fostered a sense of competition and encouraged students to improve their performance to climb the ranks.
4. Challenges and quests: The course content was structured into thematic challenges and quests. Each week, students embarked on a new quest, which consisted of a series of tasks and activities related to the week's learning objectives. Completing a quest unlocked new content and additional rewards.

The application supporting these gamification elements was user-friendly and accessible through both desktop and mobile devices. It featured an intuitive interface that guided students through their learning journey. Key functionalities included:

1. Dashboard: A personalized dashboard where students could track their progress, view earned badges, and see their current standing on the leaderboard.
2. Interactive lessons: Multimedia-rich lessons incorporating videos, interactive simulations, and practice exercises.
3. Real-time feedback: Immediate feedback on quizzes and assignments to help students identify areas for improvement.
4. Collaboration tools: Features enabling group work and peer-to-peer interactions, such as discussion forums and collaborative project spaces.

Data Collection Tools

The study mainly used quantitative data collection methods. The data were collected through three tools: (1) pretest, (2) posttest, and (3) achievement. The aim of the pretest of academic achievement was to check if participants in the experimental and control groups fulfilled the same minimum criteria of prior knowledge and skills in digital literacy. While the purpose of the posttest was to assess participants' assessment of digital literacy taught throughout the semester and to investigate whether there were differences between the 2 groups (experimental and control) using different teaching approaches, that is, game based and conventional, during weeks 11 - 16 of the semester. These tests were developed by the instructor of the course and were validated by 2 senior professors of digital literacy with more than 10 years' experience of teaching courses in the area of digital literacy.

The survey questionnaire used in this study was administered to the participants in the experimental group only. It was aimed to measure participants' perceptions of gamification regarding their perceived usefulness, ease of use, and their intension to use gamification in future. This was modified from a scale developed by Ghani et al [30]. It consisted of 20 items such as "The educational digital game will improve my learning performance," "I find the educational digital game is easy to use," and "Studying using the educational digital game is a good idea." (see Multimedia Appendix 1). The responses for the items were scored on a 5-point scale, with 1, 2, 3, 4, and 5 representing "strongly disagree," "disagree," "neutral," "agree," and "strongly agree," respectively. The internal consistency of the scale was found to be acceptable with a Cronbach α value of 0.81 [31].

Data Analysis

All data preprocessing and analyses were conducted using SPSS (version 21; IBM Corp). Statistical assumptions for parametric tests were checked and confirmed before running the main analyses [31]. Data analysis included descriptive statistics and inferential analysis including independent sample *t* test, 1-way between-subject ANOVA, and linear regression. Prior to conducting inferential statistical analyses, we tested for the assumptions underlying each statistical test. For the independent sample *t* test and ANOVA, we assessed the normality of data distribution using the Shapiro-Wilk test and ensured homogeneity of variances through Levene test. Additionally, the assumptions of linearity, independence of residuals, and homoscedasticity were confirmed for regression analysis. Moreover, Cronbach α was assessed to check the reliability of the instruments used.

Ethical Considerations

This randomized controlled trial study was approved by the standing committee for Scientific Research Ethics of King Saud University (approval KSU-HE-22 - 871). However, the trial was not registered by a clinical trial registration organization as it did not involve an explicit medical treatment.

Results

This study primarily aimed to investigate the impact of gamification on students' learning outcomes in a digital literacy course and to understand their perceptions and acceptance of gamification for their learning. The main results of this study are presented question-wise in the following sections.

Impact of Gamification on Learning Outcomes

Our first question was focused on investigating whether there was any significant impact of the gamified learning experience on students' learning outcomes. In specific terms, we wanted to check if there were significant differences in the academic achievement between the students who were taught using the gamified learning approach and those who were taught using conventional teaching methods in a digital literacy course at the undergraduate level. This question was analyzed using two main variables: (1) students' scores in the achievement test conducted at the end of the term as dependent variable in the analysis and (2) students' group (control and experimental) as an independent variable in the analysis. The dependent variable was measured on a scale with quantitative values ranging from 0 to 25, while the independent variable was recorded as a nominal variable with only 2 possible values: 1 representing the control group and 2 representing the experimental group.

The results of an independent-sample *t* test indicated that there was significant differences in students' academic performance between those who were taught using conventional teaching methods (median 15.87, SD 2.15) and those whose learning was supported with gamification (mean 21.00, SD 1.88) in a digital literacy class (t_{166}=−16.435; *P*=.001; Table 1). In simpler words, the experimental group performed better than the control group in the academic achievement test that was conducted as a summative assessment in the class. Overall, this finding suggests that the use of the gamification approach in the teaching of digital literacy proves to be an effective instructional approach at the undergraduate level.

Table . Independent *t* test results to test the impact of gamification.

		Participants, n (%)	Mean (SD)	*t* test (*df*)	*P* value
Group				–16.435 (166)	.001
	Control	84 (50)	15.87 (2.15)		
	Experimental	84 (50)	21.00 (1.88)		

Acceptance of Gamification by the Students

The second research question proposed in this study seeks to find the factors that influence the acceptance of students toward gamified learning experiences in a digital literacy course. Students' acceptance of a gamified learning experience was measured in terms of their attitude toward gamification for learning digital literacy. This variable was measured through Likert scale (ordinal type variables) items and was computed by taking the average of all items within the scale. Overall, the results indicated that the participants reported a high level of satisfaction (mean 3.857, SD 0.61) with their gamified learning experience in a digital literacy course. Regarding the factors influencing the acceptance of gamification by the students, we tested factors including age and the major of their degrees. Depending on the nature of variables, that is, scale variables and nominal variables with more than 2 levels, we used different statistical tests for the analysis of this research question.

The results of simple linear regression and 1-way between-subject ANOVA revealed that the major of the degree program was not a significant factor for participants' acceptance of gamification in a digital literacy class (P=.06). Similarly, a simple linear regression analysis did not find age as a significant predictor of acceptance of gamification (P=.06). All in all, these results suggest that neither age nor major of degree are factors for participants' high level of acceptance of gamified learning. The participants in this study showed a positive attitude toward the acceptance of gamification in a digital literacy course regardless of their age or the academic discipline of their degrees.

Effect of Learners' Prior Experience With Gamification

In the third question of the study, we were interested to confirm if participants' prior experience with gamification affects their reported acceptance of gamified learning for a digital literacy course. For the analysis of this question, participants' acceptance score served as the dependent variable, which was measured as a scale type variable, while their prior experience served as the independent variable, which was measured as a nominal variable with three levels: "no experience," "little experience," and "extended experience." About one-third of the participants (n=26, 31%) had no prior experience of gamification. A total of 33 (39.3%) the participants reported that they had little experience of using games for learning. Likewise, 29.8% (n=25) of the participants had extended prior experience of gamification.

Since the levels of the independent variable were more than two, a 1-way between-subject ANOVA was chosen for the analysis of this question. The ANOVA results showed that there was no statistically significant difference in participants' acceptance of gamified learning for the digital literacy course in respect to their prior experience of gamification ($F_{2,81}$=1.319; P=.27; Table 2 for details). Since the main result of the ANOVA analysis was found to be nonsignificant, further post hoc analysis was not needed. These results suggested that regardless of the participants' differences in their prior experience of gamification (some were not exposed to this teaching strategy, while some were experienced with it), their current level of acceptance for the gamified learning experience of digital literacy was almost similar.

Table . ANOVA results showing the influence of prior experience of gamification.

		Sum of squares (*df*)	Mean square	*F* test (*df*)	*P* value
Analyses				1.319 (2,81)	.27
	Between groups	0.974 (2)	0.487		
	Within groups	29.914 (81)	0.369		
Total		30.888 (83)	—[a]	—	—

[a]Not applicable.

Discussion

Principal Results

The ultimate goal of the study was to investigate the impact and acceptance of gamification in a digital literacy course at the undergraduate level. To achieve this goal, we addressed 3 research questions. The findings of these questions are discussed below.

For RQ1, we found that there was a significant difference in academic performance between students who were taught using conventional teaching methods and those who experienced gamified learning. Specifically, the experimental group, which was exposed to gamification, achieved a higher mean score (21.00) compared to the control group (mean 15.87), which received traditional teaching methods. This finding supports the notion that gamification can be an effective educational tool to enhance learning outcomes [32]. This finding has practical implications for educators and instructional designers. By implementing the game-based elements into the learning environment, instructors can potentially construct a more engaging and satisfying learning environment for learners [33]. Gamification techniques, such as scoring, badges, leaderboards, and interactive challenges, may foster a sense of competition, achievement, and enjoyment, helping to achieve better learning outcomes.

The data for this study show a high level of satisfaction (mean 3.857) with the gamified learning experience in a digital literacy course. The mean value being close to the upper end of the Likert scale (5) suggests that students generally had a positive attitude toward gamification as a learning approach. Our results are not different to the results of other studies that provide evidence for learners' higher level of satisfaction with gamified learning [34-38]. This positive attitude is a promising indicator of the potential effectiveness of gamification in enhancing student engagement and motivation.

The study findings demonstrate that age is not a significant factor influencing students' acceptance of gamified learning experiences. In this context, it means that students across different age groups showed similar levels of acceptance toward gamification. Although this finding suggests that gamified learning experiences can be suitable for a diverse range of age groups within the undergraduate level, it is important to acknowledge that the limited age range (18-22 years) of the participants in this study restricts our ability to draw strong conclusions about the impact of age on gamification acceptance. In addition, the finding of this study about age is different from what is suggested by Denden et al [38]. They found that "age" moderates the relationship between their experience of participating in a gamification program and perceived self-efficacy, such that it exerts a greater influence on older people.

Further, we found that the major of degree programs does not significantly impact students' acceptance of gamification in a digital literacy course. In other words, regardless of their academic disciplines, students were similarly receptive to the gamified learning approach. This result is encouraging, as it suggests that gamification can be applied in various subject areas without compromising its acceptance among students.

The nonsignificant effects of age and the major of degree on students' acceptance of gamified learning experiences have practical implications. It indicates that gamification has broad applicability and can be effectively integrated into digital literacy courses, irrespective of students' demographic characteristics or academic backgrounds. Educators can use gamification as a versatile tool to enhance student engagement and motivation across diverse student populations.

Lastly, we found that the participants had varying levels of prior experience with gamification. However, there was no statistically significant difference in participants' acceptance of gamified learning based on their prior experience with gamification. The 1-way between-subject ANOVA did not show any significant effect of prior experience (with 3 levels: no experience, little experience, and extended experience) on participants' acceptance scores. In other words, whether participants had no exposure to gamification or considerable experience with it, their acceptance of gamified learning in a digital literacy course remained similar. It suggests that even students who have never been exposed to gamified learning strategies can still embrace and appreciate the approach. Additionally, students with previous experience with gamification did not necessarily have a more positive attitude toward it compared to their peers who had no experience. This implies that the effectiveness and acceptance of gamified learning can extend to a wide range of students with different levels of exposure to gamification.

Limitations

While this study contributes valuable insights into the impact and acceptance of gamification in a digital literacy course at the undergraduate level, it is essential to acknowledge certain limitations. First, the research was conducted in a specific educational context, which may restrict the generalizability of the findings to other disciplines or educational levels. The use of convenience sampling, while practical for this study, further constrains the diversity of the participant pool. This sampling technique can lead to selection bias, as the sample may not be representative of the larger population. Future studies should aim to replicate this research with more diverse populations to explore the potential differences in gamification acceptance across various demographic and cultural groups.

The participant group, consisting of 168 native Arab speakers aged between 18 and 22 years from a single university, represents a fairly homogenous demographic. This homogeneity, while facilitating a focused analysis within this specific context, limits the broader applicability of our results. Another critical limitation arising from this homogeneity is the reduced variability in cultural background and academic exposure. Given the relatively homogeneous nature of our sample, caution should be exercised in extrapolating our conclusions to populations with greater age diversity or differing backgrounds. Future research endeavors should strive to recruit participants from a wider age spectrum to better understand the influence of age on acceptance of gamification in educational contexts. Additionally, exploring cultural and contextual factors beyond age could provide further insights into the acceptance and effectiveness of gamified learning experiences across diverse learner populations.

In addition, the study focused on a single course, and the participants were from a particular institution, which may limit the diversity of the sample. Additionally, the self-reported nature of some data, such as prior experience and acceptance scores, may have introduced response bias. Future research could address these limitations by conducting similar investigations in diverse educational settings with larger and more representative samples. Future studies could also explore the long-term effects of gamified learning experiences on students' retention of knowledge, skill development, and continued motivation in subsequent courses or academic years. Longitudinal research can offer deeper insights into the sustained benefits of gamification in educational settings.

Conclusions

In conclusion, this study sheds light on the impact and acceptance of gamification in a digital literacy course at the undergraduate level. The findings of our study have both theoretical and practical implications. The research reveals that gamified learning experiences positively influence students' academic performance, leading to higher achievement compared to conventional teaching methods. This study also demonstrates that the students' level of acceptability for gamified learning is not affected by prior experience of gamification. Educators and instructional designers can leverage the insights gained from this study to create more engaging and effective learning environments that foster student motivation and satisfaction. As the educational landscape continues to evolve, the integration of gamification into pedagogical practices stands as a promising approach to enriching the learning experiences of students in digital literacy courses and beyond.

Abstract

Background: Effective interprofessional teamwork is vital for ensuring high-quality patient care, especially in emergency medicine. However, interprofessional education often fails to facilitate meaningful interaction among health care disciplines. It is therefore imperative to afford early opportunities for cultivating interprofessional teamwork skills. While in-person simulation-based training has been shown to improve performance, this is resource-intensive, especially if it involves multiple professions. Virtual reality (VR)–based training is an innovative instructional approach that demands fewer resources and offers the flexibility of location-independent learning.

Objective: This study aimed to develop and evaluate the acceptance, learning outcome, and feasibility of an interprofessional team (INTEAM) training course that included a VR simulation of a neurological emergency case.

Methods: This 1-group study used a pre- and posttest design to evaluate the 2-hour INTEAM training course for nursing and medical students. The course included an e-learning part, VR simulation, and debriefing. The main learning objectives were derived from the entrustable professional activity 6, namely to handle a common problem in emergency medicine (headache due to subarachnoid hemorrhage and epileptic seizure) that requires interprofessional collaboration, including a structured handover. We used validated and self-constructed questionnaires, pre- and posttests, and open questions to assess the acceptance, learning outcome, and feasibility of the course.

Results: The data of 42 students (21 nursing and 21 medical students) were analyzed and showed good usability in the System Usability Scale (median 72.5, IQR 65 - 80). The perception of usefulness (median 6, IQR 5.8 - 6.9) and ease of use (median 5.9, IQR 5.1 - 6.3) was good among all students. There was a significant increase in the handover performance from pre- (median 8, IQR 6 - 9) to posttraining (median 8, IQR 7 - 9; z=−2.01; P=.045; r=0.33) and of the confidence in caring for patients with seizures (median 3, IQR 2 - 3 and median 3.5, IQR 3 - 4, respectively; z=−3.8; P<.001; r=0.60). In 67% (14/21) of the simulations, technical issues occurred, but all simulations could be carried out completely.

Conclusions: The new INTEAM training course was well received by nursing and medical students. The handover skills and confidence in caring for patients with seizures were improved after the course. Despite technical challenges with the VR simulations, none required termination, and this demonstrates that our approach is feasible. These promising results encourage the use of VR simulations for team training in the education of nursing and medical students.

Introduction

In all branches of medicine, seamless collaboration between health care professionals, such as physicians and nurses, is essential in achieving optimal patient care and a high level of patient safety [1-3]. This need is particularly pronounced in emergency medicine, where rapid and coordinated teamwork is critical to managing life-threatening situations [2]. Although teamwork is so important for patient outcomes, there is hardly any time to practice this during work [4], especially in the emergency department. One way to counteract this is to integrate interprofessional education (IPE) into the curriculum of health professionals [2,5-7]. IPE involves students from at least 2 different health care professions, who must learn to understand their respective roles and responsibilities and practice their communication skills and thereby enhance their ability to work seamlessly together in real emergency situations [4,7-10].

The importance of IPE during undergraduate studies is widely recognized, and efforts are underway worldwide to integrate this into health care education [4,11-13]. In Switzerland, for example, the Federal Law on Health Professions requires "familiarity with the interaction between different health professions" as a necessary expertise for graduates [14]. Consequently, Swiss nursing education has made progress in promoting interprofessional collaboration through joint educational activities involving diverse professions, such as midwives, nutritionists, and physiotherapists [15]. In Swiss medical education, the importance of interprofessional work has also been recognized, as is seen in its inclusion in the medical licensing examination. However, it has not been consistently integrated into the curriculum [16]. Previous interprofessional courses have faced challenges and some have been discontinued, in part due to the COVID-19 pandemic [17,18]. As a result, there remains a lack of interaction between nursing and medical students. Addressing this issue is critical given the lifelong collaboration between these professions in the medical field.

To foster interprofessional collaboration and enhance student teamwork skills, team training is an effective approach, as evidenced by numerous reviews [5-7,19]. Team training is commonly conducted through real-life simulations, "a technique...to replace or amplify real experiences with guided experiences, often immersive in nature, that evoke or replicate substantial aspects of the real world in a fully interactive fashion" [20]. Such simulations are frequently carried out in simulation centers, although these require substantial resources, and this limits their accessibility [6,21]. Virtual reality (VR)–based training is an innovative and resource-efficient alternative, which offers immersive experiences that simulate real-world scenarios [22,23]. Current research suggests that VR simulations are at least as effective as real-life simulations and offer advantages such as reduced costs, accessibility, and the ability to practice challenging scenarios [24-28].

Our objective was therefore to develop and evaluate an interprofessional team (INTEAM) training course for students that uses a VR simulation to provide them with an authentic training experience of handling an emergency case, coupled to interprofessional communication. We now report the development, content, and evaluation of the INTEAM training course "Patient handover and headache." We specifically aimed to assess the acceptance (usability, VR-induced sickness, sense of presence, workload, user satisfaction, and technology acceptance) of the VR simulation among nursing and medical students, with comparisons between study programs and genders; its learning outcome among nursing and medical students, including comparisons between study programs; and its feasibility.

Methods

Study Design and Setting

In this evaluation study, a 1-group pre- and posttest design was used. Data collection took place in May 2023 digitally and in a training facility of the University Hospital of Bern, Switzerland.

Beyond the reported data, additional data on the validation of the TEAM (Team Emergency Assessment Measure) instrument [29] collected during the project was reported elsewhere [30]. The data presented in the 2 papers do not overlap, with the exception of demographic information.

Ethical Considerations

The local ethics committee (Kantonale Ethikkommission Bern) deemed our study to be exempt from full ethical approval, as it is not covered by the Human Research Act (BASEC-Nr: Req-2023 - 00208).

Participants and Eligibility Criteria

The study population was a convenience sample of adult (≥18 years of age) final-year medical students of the University of Bern and adult (≥18 years of age) final-year bachelor nursing students of Bern University of Applied Sciences. The project was presented to them by their teachers. Students could volunteer for the course at their university (nursing) or enroll themselves through the course portal (medicine) as one of several optional courses in the spring semester. No compensation was provided. Written informed consent for study participation and publication of study results was obtained from each student.

Exclusion criteria included unwillingness to participate or give informed consent. Students experiencing epilepsy or other sensitivity to flashing light were also excluded.

Training Course

Overview

The development of the INTEAM training course in emergency medicine involved experts from various disciplines, including emergency physicians, nurses, medical educators, and psychologists, who determined the learning objectives based on the entrustable professional activity (EPA) and designed the course content and material and the VR case scenario. Given the course's focus on EPA 6—"Recognize a patient requiring urgent/emergency care, initiate evaluation and management" [16]—the team specifically selected a common emergency medical scenario that required seamless interprofessional collaboration, including 2 structured handovers.

To reduce the time needed for the on-site training, we decided to include an e-learning part that had to be accomplished at home in preparation of the on-site part. The e-learning part aimed at refreshing the major contents of the simulation (headache with red flags, epileptic seizure, and the handover tool "Introduction, Situation, Background, Assessment, and Recommendation" [ISBAR] [31-33]), which had already been covered by the respective curricula.

The on-site part was scheduled for 3 consecutive days, with each day consisting of 3 separate 3-hour time slots. Per slot, 6 students were invited (3 nursing and 3 medical students), as we had 3 rooms and 3 moderators available. Upon arrival, students were given a prebriefing and an orientation tour to introduce them to the upcoming VR simulation. In the VR simulation, the nursing and medical students had the opportunity to practice their future role as nurses or physicians, including their teamwork, as interprofessional pairs in a specific emergency situation. After the simulation, students participated in a debriefing to reflect on their experience and learning points.

e-Learning

Students received a link to the e-learning part approximately 1 week before the on-site session. The e-learning part consisted of 2 videos of 10 minutes each. In the first video, an emergency physician and an advanced practice nurse—with the support of a facilitator—gave an overview of headaches and epileptic seizures (ie, clinical manifestation, diagnostics, and therapy) and shared their best practices. In the second video, the same team presented the dos and don'ts of handovers and emphasized the ISBAR handover tool together with a typical demonstration. Students were also pointed to a written summary of the presentation, further examples, and background material.

VR Simulation

Development

The interdisciplinary author team developed the simulation case, with input from a company for immersive technologies in the health care sector (StellDirVor GmbH). The implementation in VR was carried out by the VR medical simulation company SimX.

The case displayed a male, 56-year-old patient initially presenting to the emergency department with a thunderclap headache and subtle neurological findings and then progressing to a generalized tonic-clonic epileptic seizure due to subarachnoid hemorrhage. The developers carefully considered the main learning objectives (following EPA 6): emergency management of a patient with thunderclap headache and epileptic seizure (including history taking); physical (including neurological) examination; use of the ABCDE (Airway, Breathing, Circulation, Disability, Exposure) approach [34] in the emergency setting; drug therapy; and conducting a structured handover using ISBAR.

Technical Details and Simulation Setup

The VR simulation setup consisted of the application of a fully immersive semiautomated supervised-learning VR training scenario using a Meta Quest 2 VR headset with Elite Straps with built-in battery, touch controllers (Meta Platforms, Inc), and noise-canceling headphones (JBL Tune 760NC). The VR simulation was controlled by a moderator using an OMEN Gaming Laptop by HP (HP Development Company), giving the appropriate prerecorded verbal responses and initiating the appropriate physiological patient response. There were 3 moderators (2 medical students and 1 PhD student with a background in nursing) and a coordinator (PhD student with a background in psychology) who received training from the study team for approximately 5 hours in the emergency scenario and the technical setup. We deliberately selected students as moderators, in concordance with the principles of peer-tutor teaching. The coordinator also served as a substitute moderator and was familiar with the VR system to help the moderators troubleshoot technical issues.

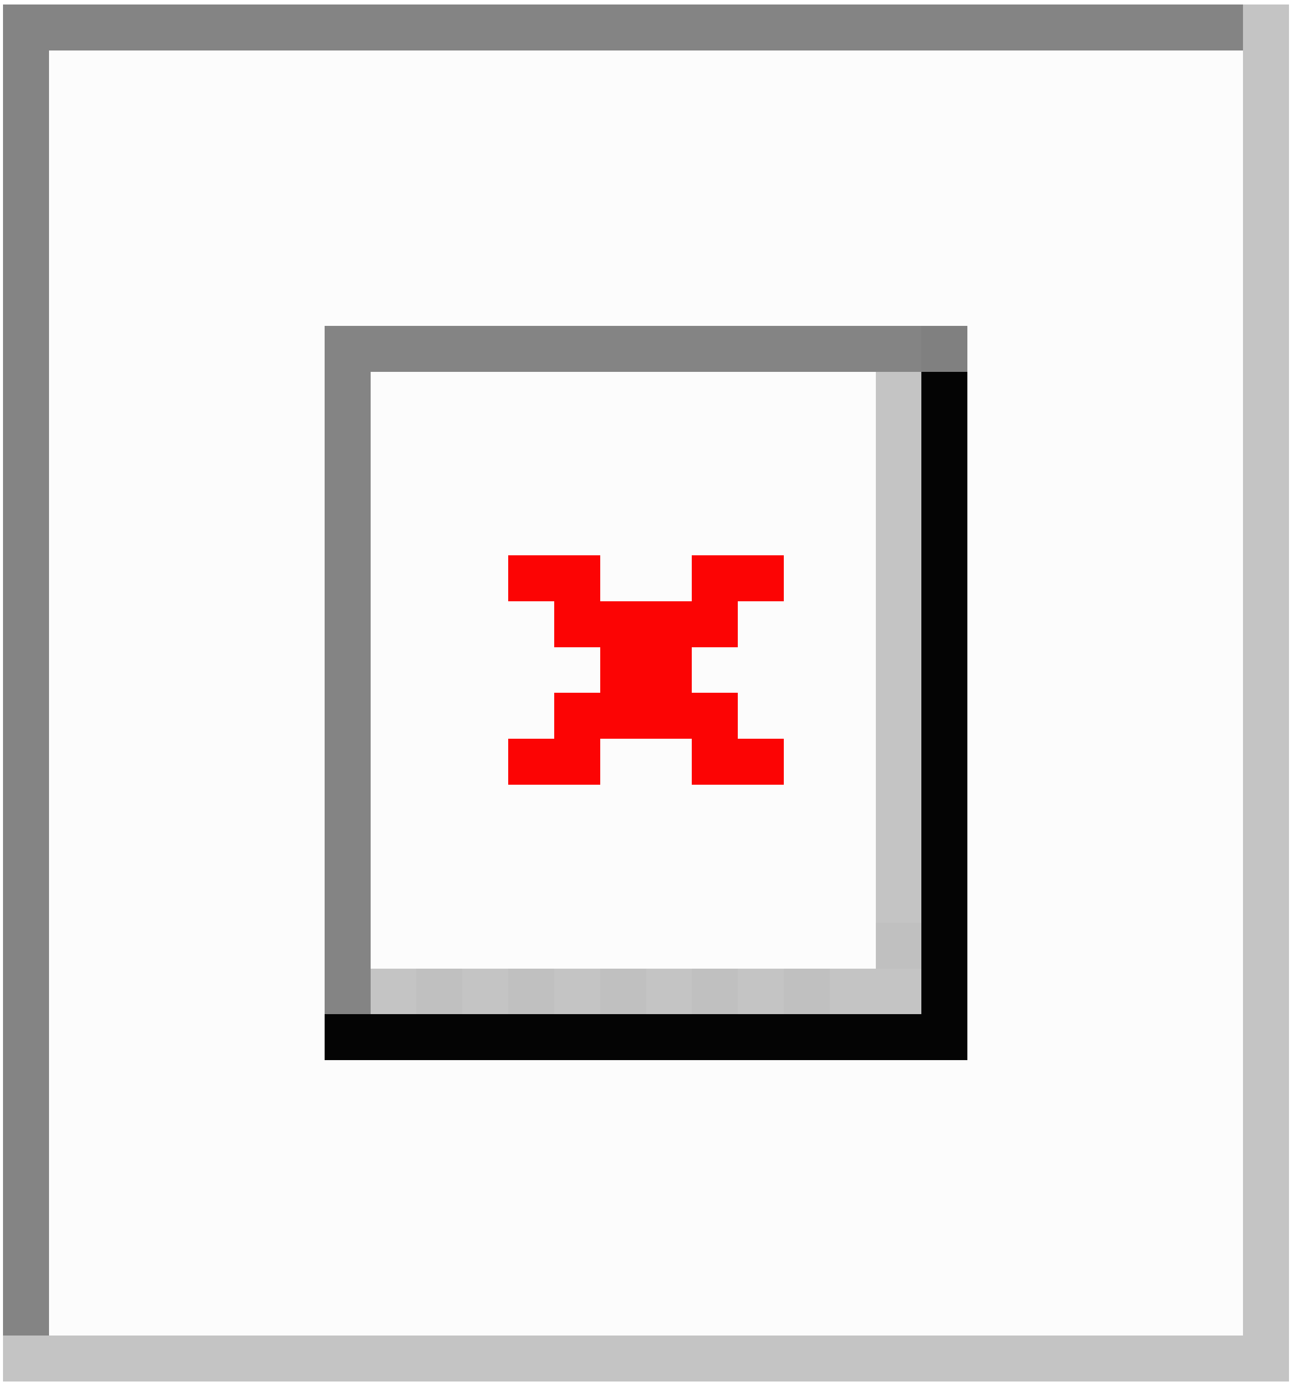
Prebriefing

At the beginning of the on-site part, we conducted a prebriefing with all 6 students to communicate the key aspects, including safety guidelines for the VR experience. We emphasized the importance of creating a safe learning environment and assured students that their performance would only be analyzed for study purposes and in pseudonymized form. We also made clear that the main aim of the course was not to assess their clinical skills but rather to explore the use of VR and an interprofessional course as an effective learning tool.

Orientation Tour

After the prebriefing, students were randomly assigned to pairs of a nursing and a medical student. Each pair was accompanied to a separate room by one of the moderators. Prior to the VR simulation, the student pairs were guided through the VR environment by the moderator in a standardized procedure. During this orientation tour, the team could familiarize themselves with their virtual surroundings and practice how to interact with the virtual environment. They were informed that their teammates' avatars would just be displayed as heads and hands in VR (Figure 1) due to the technical setup of the simulation software. The students were also instructed to speak in standard German, without using dialects, but the patient would respond in English.

Figure 1. Participants in the VR simulation (**A**) in the real training room and (**B**) in the VR patient room. The circles illustrate the corresponding avatars. VR: virtual reality.



Content of VR Simulation

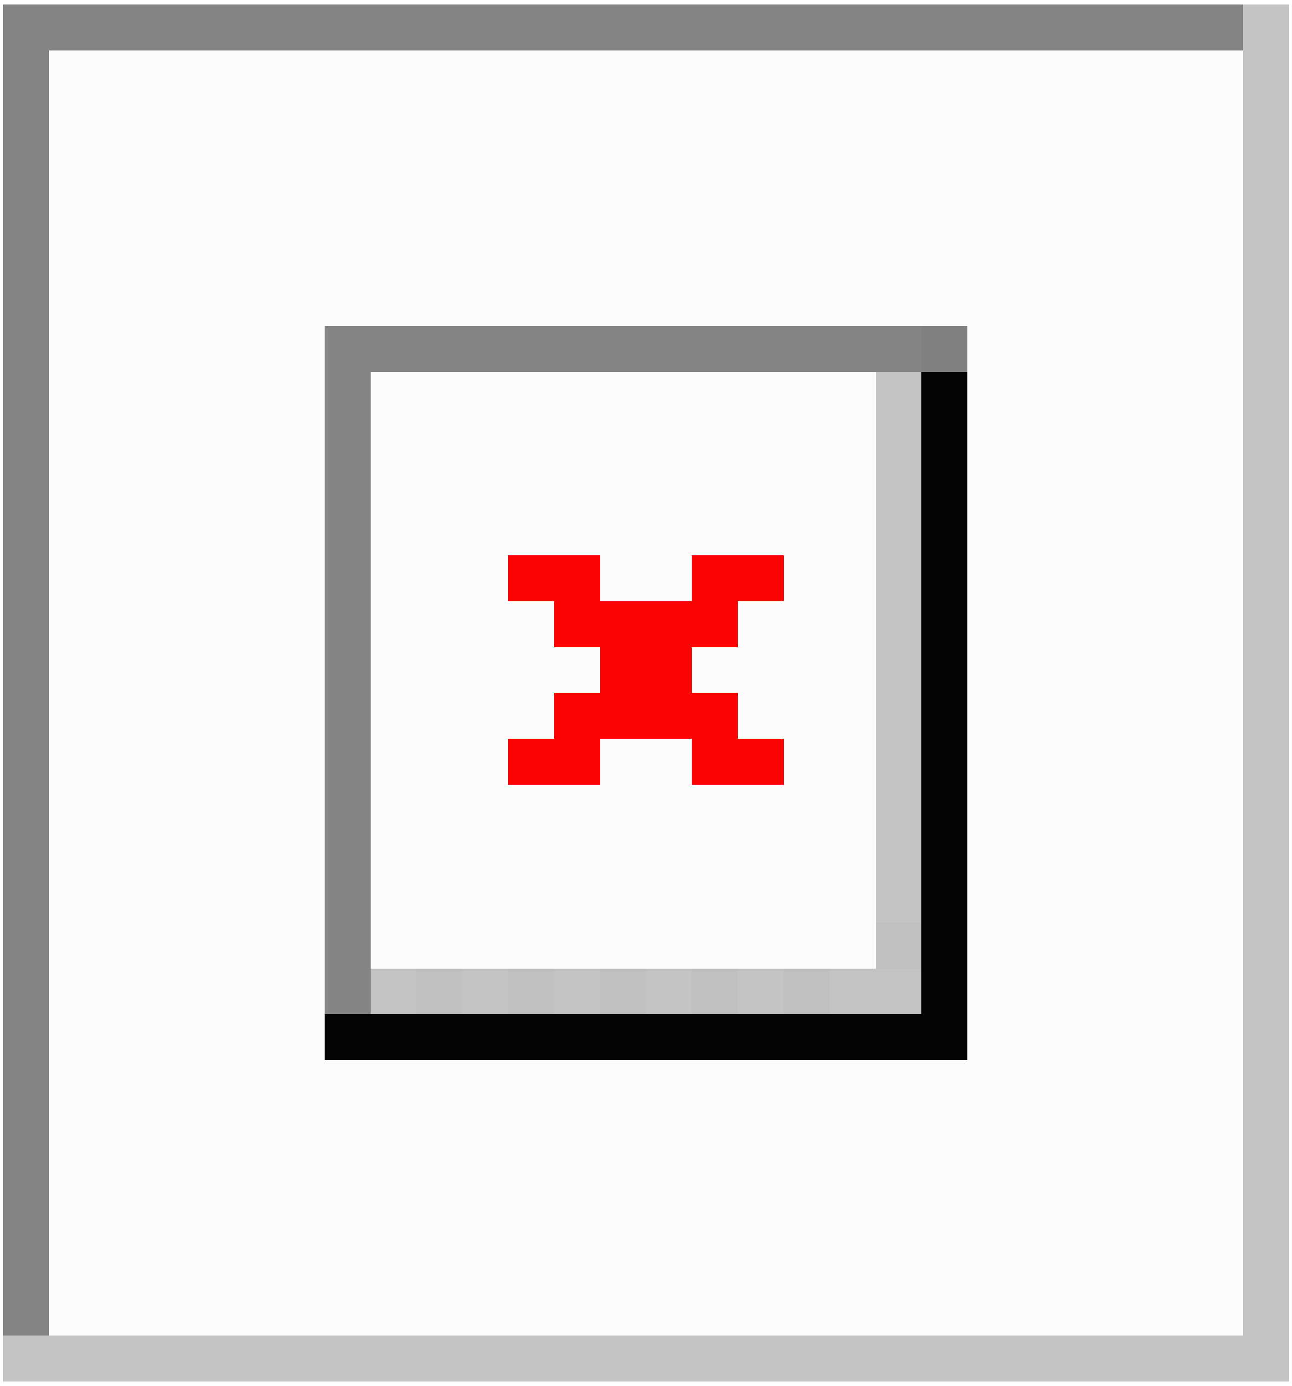
Before entering the virtual patient room, the nursing student received a brief written instruction from the moderator:

> *You are a nurse working in a local hospital. You are called to a room in the emergency department to see a new patient. The patient has walked in on his own and has not yet been seen by a physician. Please perform the initial assessment. The physician will soon come to support you. The physician on duty will knock on the door and then support you.*

The student nurse then started to take the history and examination of the patient who presented with a severe headache and who was accompanied by his wife (nurse assessment, Figure 2). In the meantime, the medical student stayed in the same (physical) room, but was unable to watch or listen to the nurse-patient interaction, and also received written instructions:

> *You are a physician working in a regional hospital. You are called to see a new walk-in patient in the emergency department. The nurse is already there and asks for your assistance. If you hear the knock [of the moderator], you can enter and introduce yourself to the nurse. If you don't get a handover from the nurse, ask for one.*

Figure 2. Virtual reality simulation scenario.



The medical student entered the VR simulation after 5 minutes, and the first handover from the nursing student to the medical student took place. The team was then able to continue taking the history and physical (including neurological) examination (team assessment). After 9 minutes (in total), the patient had an epileptic seizure, which required emergency care such as placing him in a stable side position and administering oxygen and medications. The seizure lasted until it was treated with benzodiazepine or anticonvulsants or ceased spontaneously without treatment at minute 17. After the seizure, the patient was unresponsive for 3 minutes (postictal), after which his cognitive state gradually improved. During this phase (team treatment), the students were able to order further diagnostics and call the attending physician. The VR simulation ended with either a self-initiated handover to the attending physician or a moderator-triggered handover at minute 23 via telephone.

Debriefing

The 30-minute lasting debriefing was conducted after the VR simulation by the moderators according to a debriefing guideline. The guideline was developed from an expert in simulation training (TCS) following the 3D Model of Debriefing [35] and included 4 subjects: defusing (How did it go? How did it feel?); discovering, including medical aspects (What was the medical problem? What did you do?); handover (Did you get all the information? What were the problems?); and deepening (What have you learned for the interprofessional teamwork?

What will you take with you to the next emergency handover?). The debriefing session was neither recorded nor analyzed.

Data Collection

Overview

Before and after the VR simulation, we administered questionnaires as outlined in Table 1. The self-constructed questionnaires can be found in Multimedia Appendix 1.

Table . Overview of all questionnaires.

Category and variable measured		Questionnaire	Point in time
Baseline			
	Age, gender, study program, prior medical education (eg, health care assistant), previous experience with VR[a] simulation and gaming, previous communication training	Self-constructed questionnaire (digital)	Baseline (approximately 2 weeks before the on-site part)
	Visual aid	Self-constructed questionnaire	Presimulation
	Acquaintance	Self-constructed questionnaire	Postsimulation
Acceptance			
	Usability	System Usability Scale [36]	Postsimulation
	VR-induced sickness	Simulator Sickness Questionnaire [37]	Postsimulation
	Sense of presence	Slater, Usoh, and Steed [38]	Postsimulation
	Subjective workload	NASA-Task Load Index [39]	Postsimulation
	User satisfaction	User Satisfaction Evaluation Questionnaire [40]	Postsimulation
	Technology acceptance	Fast Form-Technology Acceptance Model [41]	Postsimulation
Learning outcomes			
	Handover skills	Clinical case vignette 1 and 2 (digital) and rated with Handover Assessment Tool [42]	Baseline and postdebriefing
	Confidence	Self-constructed questionnaire	Baseline and postdebriefing
	Perceived effectiveness	Training Evaluation Inventory [43]	Postsimulation
Feasibility			
	Duration, technical problems, attendance of on-site part	Self-constructed questionnaire (moderator)	On-site part
	Evaluation of the e-learning, VR simulation, and debriefing regarding the achievement of the learning objectives, grade, and suggestions for improvement	Self-constructed questionnaire	Postdebriefing
	Overall comments (regarding feasibility)	Free text	Postdebriefing

[a]VR: virtual reality.

Baseline Data

All students had to fill in a web-based questionnaire via SosciSurvey before starting the INTEAM training course. The link to the questionnaire was sent to students approximately 2 weeks before the on-site session and 1 week before the e-learning. It included questions about sociodemographic factors (age, gender, study program, and prior medical education), previous experience with VR simulation and gaming, and previous communication training (in hours). The use of visual aids was assessed in a survey right before the VR simulation. The students were also asked whether they knew their assigned team partner.

Acceptance

The following questionnaires were completed by the students immediately after the VR simulation.

Usability was assessed using the System Usability Scale (SUS) [36], which consisted of 10 questions to be rated on a 5-point

Likert scale, ranging from 1=strongly disagree to 5=strongly agree. Ratings were then converted so that the resulting SUS score ranges from 0 to 100, with scores lower than 50 being regarded as concerning [36,44].

VR-induced sickness was assessed with the Simulator Sickness Questionnaire (SSQ) [37], where the students had to rate 16 symptoms (eg, nausea and headache) on a 4-point Likert scale from 0=none to 3=severe. Ratings were then converted into 3 subscores and a total score. A total SSQ score above 20 is an indicator of a poor simulator according to Stanney et al [45].

Sense of presence in the virtual world was assessed using the 6-item questionnaire developed by Slater, Usoh, and Steed [38,46], using a semantic differential scale (eg, 1=being elsewhere and 7=sense of being in the virtual environment), with a mean score of 7 representing the strongest sense of presence.

Perceived subjective workload was assessed using the NASA (National Aeronautics and Space Administration)–Task Load Index (NASA-TLX) [39]. The NASA-TLX was calculated by weighting 6 dimensions (mental demand, physical demand, temporal demand, performance, effort, and frustration) assigned by the respondent, with each dimension's rating, and summing these weighted values. The calculated total score can range from 0 to 100, with higher scores indicating more perceived subjective workload.

User satisfaction was assessed using the User Satisfaction Evaluation Questionnaire [40], comprising 6 questions with a 5-point Likert scale from 1=not at all to 5=very much. The total score can range from 6=poor satisfaction to 30=excellent satisfaction.

Technology acceptance was measured using the Fast Form-Technology Acceptance Model (FF-TAM) [41,47], comprising 12 items scored on a 7-point semantic differential scale (eg, 1=ineffective and 7=effective). The FF-TAM mean score ranges from 1 to 7. Higher scores reflect an increased likelihood of technology acceptance based on the subscales usefulness (items 1 - 6) and ease of use (items 7 - 12).

Learning Outcome

As one of the learning objectives was to practice a structured handover using ISBAR, handover skills were assessed with a pre- and posttest to assess the training's learning outcome. The pretest took place as part of the web-based questionnaire mentioned earlier prior to the commencement of the e-learning. For this, students were given 4 minutes to read a clinical case vignette (case 1) and take notes. The screen then automatically showed the next page, where they were instructed to record a verbal, structured handover of the case within 1 minute. The posttest took place after the debriefing, following the same procedure as in the pretest, now with a different clinical case vignette (case 2; Multimedia Appendix 2). Both handovers were transcribed and assessed by 1 trained rater (ANN) using the Handover Assessment Tool (HAT) [42], which was adapted for our study purposes (Multimedia Appendix 3). The tool comprises 12 items and follows the ISBAR framework, resulting in a total score of 0 - 12 points, with higher values indicating better adherence to the ISBAR framework. To capture the perceived learning outcome, confidence was assessed at baseline in the web-based survey and after the INTEAM training course using a self-constructed 4-item questionnaire ("rate your confidence when (1) caring for a patient with a seizure, (2) making a structured handover of an emergency patient, (3) recognizing when to call for help in an emergency situation, and (4) working with a person from another profession") on a 5-point Likert scale (1=very low to 5=very high). The confidence items were based on items from Kolbe et al [12] and have already been tested in a study by Birrenbach et al [48] as well as in the pilot.

In addition, the perceived effectiveness of the VR simulation was measured immediately after the simulation using the Training Evaluation Inventory [43], which consists of 17 statements regarding 5 subscores: subjective enjoyment, perceived usefulness, perceived difficulty, subjective knowledge gain, and attitude toward the training, scored on a 5-point Likert scale ranging from 1=strongly disagree to 5=strongly agree.

Feasibility

To assess the feasibility of the training, notes were taken by the moderator on the duration of the orientation and the VR simulation as well as on any technical problems or other comments regarding the on-site part. The notes of all training were summarized and analyzed descriptively.

The students also evaluated the e-learning, the VR simulation, and the debriefing separately after the debriefing session by answering 3 questions: "How well did this part contribute to achieving the learning objectives?" (1=not at all to 6=very well), "What grade would you give this part?" (1=worst to 6=best), and "Do you have any suggestions for improvement?" (free text). Students were also asked to write down their most important learning experience during the course (free text). There was also space for overall comments regarding feasibility (free text). The free-text responses were coded by one of the authors (ANN), then summarized, and analyzed descriptively.

Statistical Analysis

The data were analyzed using SPSS (version 28.0; IBM Corp) and stored in pseudonymized form. Only the data of complete teams were analyzed. Descriptive statistics, the Mann-Whitney *U* test, and the Fisher exact test were used to compare the baseline characteristics between groups.

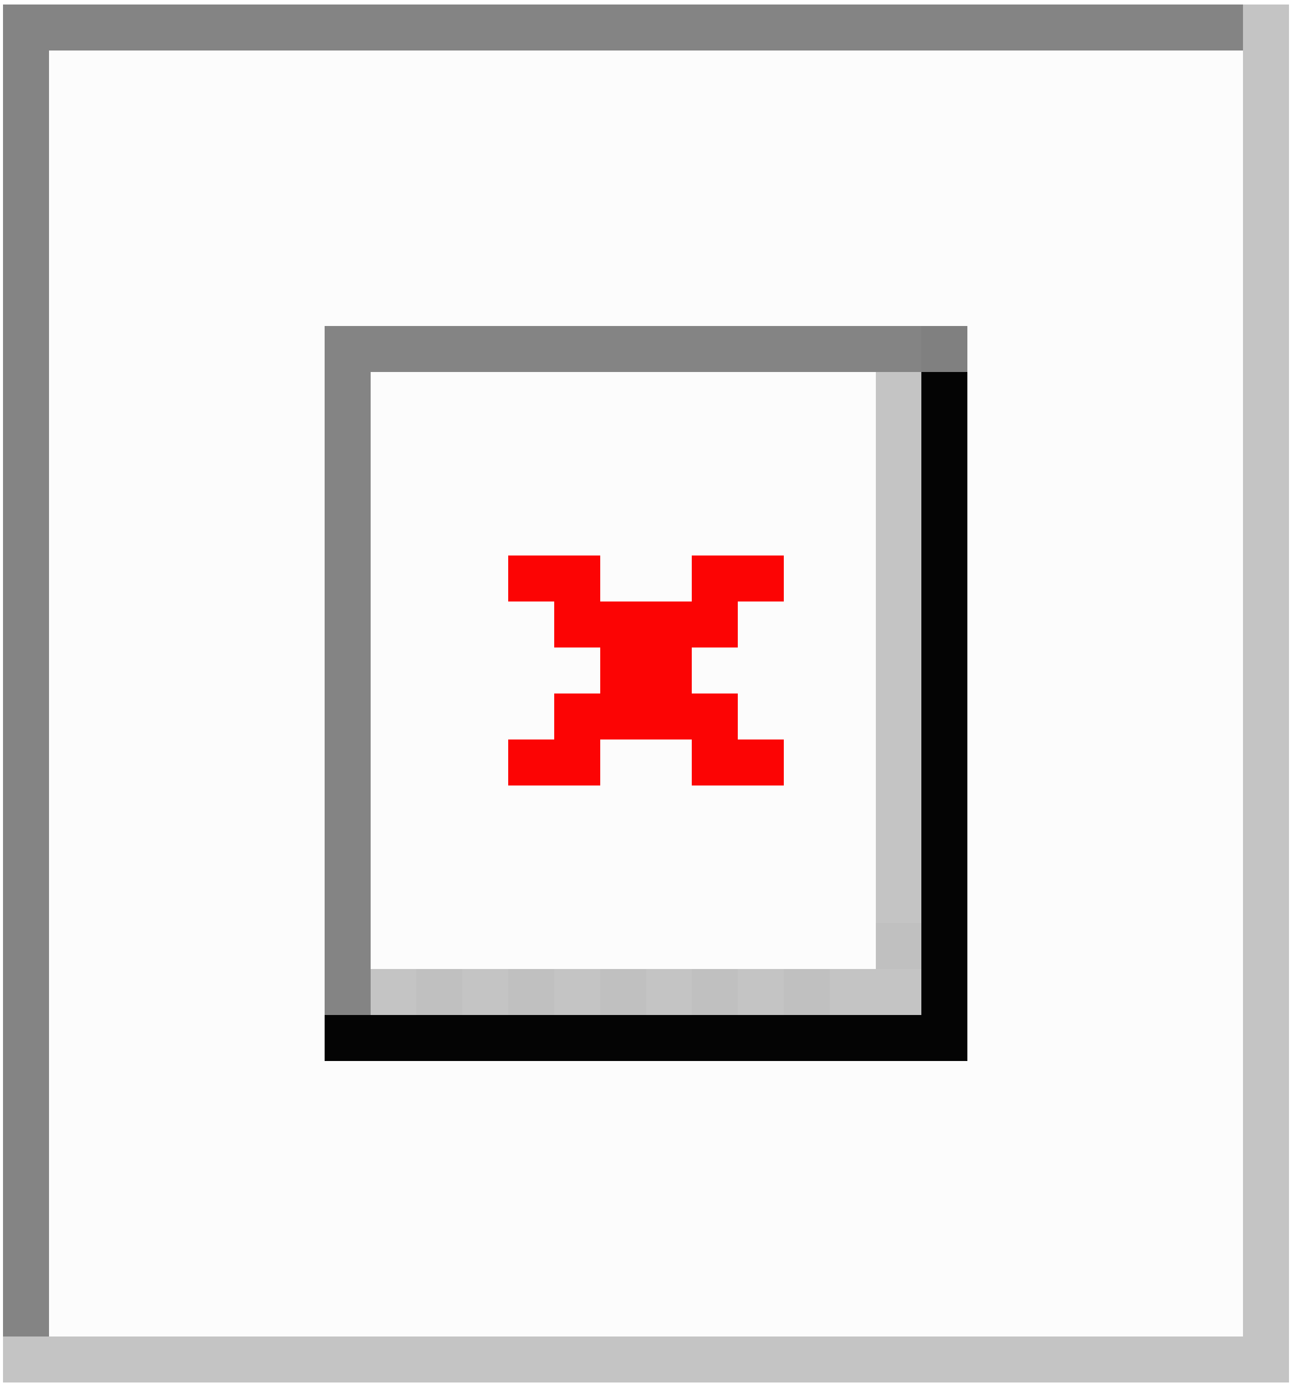
Wilcoxon signed rank tests were performed for pre- and postsimulation comparisons (ie, handover skills and confidence). The Mann-Whitney *U* test was used to compare the questionnaire results of medical with those of nursing students and of women with those of men. A P value of <.05 was considered statistically significant.

Results

Overview

As shown in Figure 3, 54 students enrolled in the course. Among them, 46 completed the e-learning part. Due to no-shows, 4 students had no team partner for the VR simulation. In these cases, the nonpaired students were still invited to conduct the simulation in a modified manner (shorter, moderator as a partner) but excluded from the evaluation. The final sample thus comprised 42 students, including 21 nursing and 21 medical students.

Figure 3. Flowchart. VR: virtual reality.



Sample Characteristics

Table 2 shows the demographic characteristics of our final sample. One nursing student did not complete the baseline questionnaire, but gender and course of study were used, as this was known. Only 1 team was familiar with each other; they had known each other for 6 years. Nursing students differed from medical students in terms of age, prior medical education, and hours of communication training, which may be explained by the different lengths of their curricula (nursing 3 years and medicine 6 years).

Table . Baseline characteristics.

Characteristics	Nursing students (n=20)	Medical students (n=21)	Total (n=41)	*P* value
Age (years), median (IQR)	23 (22 - 24)	26 (25 - 28.5)	25 (23 - 26)	*<.001*[a, b]

Acceptance

To quantify the acceptance of the VR simulation, we report the median scores of the usability, VR-induced sickness, sense of presence, subjective workload, user satisfaction, and technology acceptance scales (Table 3).

Table . Acceptance variables.

	Nursing students (n=21), median (IQR)	Medical students (n=21), median (IQR)	Total (n=42), median (IQR)	*P* value[a]
Usability: SUS[b] (score ranges 0 to 100, higher=better)				
Total score	70 (65 - 81.3)	77.5 (67.5 - 80)	72.5 (65-80)	.34
Virtual reality–induced sickness: SSQ[c] (total score ranges 0 to 236, higher=more symptoms)				
Total score	30 (11 - 43)	26 (13 - 37)	26 (11 - 41)	.34
Nausea	19.1 (9.5 - 28.6)	19.1 (0 - 28.6)	19.1 (9.5 - 28.6)	.11
Oculomotor	45.5 (15.2 - 60.6)	37.9 (15.2 - 60.6)	37.9 (15.2 - 60.6)	.99
Disorientation	41.8 (20.9 - 83.5)	41.8 (27.8 - 62.6)	41.8 (27.8 - 73.1)	.66
Sense of presence: Slater, Usoh, and Steed (score ranges 0 to 7, 7=strongest sense of presence)				
Total score	5 (4.3 - 5.4)	4.5 (3.9 - 5.5)	4.8 (4.1 - 5.5)	.86
Subjective workload: NASA-TLX[d] (score ranges 0 to 100, higher=more workload)				
Total score	64.3 (60 - 69.2)	64.7 (55.2 - 71.3)	64.5 (59.6 - 70.7)	.89
User satisfaction: USEQ[e] (score ranges from 6=poor satisfaction to 30=excellent satisfaction)				
Total score	24 (21.5 - 28)	25 (23 - 27)	25 (22.8 - 27)	.93
Technology acceptance: FF-TAM[f] (score ranges from 1 to 7, higher=better)				
Subscore				
Usefulness	6.3 (5.8 - 6.8)	6 (5.5 - 6.5)	6 (5.8 - 6.9)	.78
Ease of use	6 (4.7 - 6.3)	5.8 (5.3 - 6.3)	5.9 (5.1 - 6.3)	.49

[a]Mann-Whitney *U* test.

[b]SUS: System Usability Scale.

[c]SSQ: Simulator Sickness Questionnaire.

[d]NASA-TLX: NASA-Task Load Index.

[e]USEQ: User Satisfaction Evaluation Questionnaire.

[f]FF-TAM: Fast Form-Technology Acceptance Model.

Usability was rated as good (SUS: median 72.5, IQR 65-80 of a maximum of 100). SSQ analysis showed moderate VR-induced sickness, primarily due to eye-related problems (eg, difficulty focusing and blurred vision). Perceived participant presence (Slater, Usoh, and Steed) was good, with a median rating of 4.8 (IQR 4.1-5.5) of a possible 7. Students also expressed positive satisfaction (User Satisfaction Evaluation Questionnaire) with the system, giving a median score of 25 (IQR 22.8-27) of a maximum 30. Moreover, technology acceptance (FF-TAM) was deemed satisfactory, with a usefulness median of 6 (IQR 5.8-6.9), and an ease of use median of 5.9 (IQR 5.1-6.3) of a possible 7. However, the workload was rated as notably high, as evidenced by a NASA-TLX median score of 64.5 (IQR 59.6-70.7) of 100.

As can be seen in the last column of Table 3, there were no significant differences between nursing and medical students (all $P≥.11$). However, there were significant differences between female (median 71.3, IQR 62.5 - 80) and male students (median 78.8, IQR 70.6 - 86.3) in the total score of the SUS, with male students rating usability higher ($z=−2.380$; $P=.02$; $r=0.37$). Additionally, female students (median 35.5, IQR 20.3 - 49.8) had significantly higher scores than male students (median 20.5, IQR 8 - 26) in the total score of the SSQ ($z=−2.586$; $P=.01$; $r=0.39$) and its subscore disorientation (median 62.6, IQR 27.8 - 90.5 and median 34.8, IQR 13.9 - 52.2, respectively; $z=−2.481$; $P=.01$; $r=0.38$).

Learning Outcome

For 36 students, we obtained complete recordings of the pre- and posttests on handover skills, which were evaluated with the HAT [42]. The recordings of 5 nursing students and 1 medical student could not be evaluated due to recording errors (blank recording, recording canceled, and recording not executed). Results indicated that nursing students had a lower pretest score than medical students (median 7, IQR 5 - 8 and median 8, IQR 7 - 9, respectively; $z=−1.93$; $P=.045$; $r=0.33$). The HAT score (all students) showed a significant increase from the pretest (median 8, IQR 6 - 9) to posttest (median 8, IQR 7 - 9; $z=−2.01$; $P=.045$; $r=0.33$).

For 41 students, we obtained complete pre- and postdebriefing confidence ratings (1 student did not fill out the pretest). At pretest, students rated their confidence as medium to high (Table 4). For 2 items (caring for patient and call for help), ratings improved at posttest but not for the other 2 ($z=−3.8$; $P<.001$; $r=0.60$ and $z=−3.0$; $P=.003$; $r=0.47$, respectively). Interestingly, medical students indicated lower confidence than nursing students at pretest for the item “working interprofessionally” ($z=−2.3$; $P=.02$; $r=0.36$).

Table . Confidence.[a]

Confidence: items	Nursing students (n=20)			Medical students (n=21)			Total (n=41)

[c]Significant values are present in italics format.

The results of the Training Evaluation Inventory indicate a high perceived effectiveness. The subscores subjective enjoyment, perceived usefulness, and attitudes toward training were rated high (median 5, IQR 4 - 5). The subscores perceived difficulty and subjective knowledge gain received medium ratings (median 4, IQR 4 - 5 and median 4, IQR 3 - 5, respectively). No significant differences were found between nursing and medical students (all *P*≥.25).

Feasibility

The mean length of the orientation tour was 26 (SD 6) minutes, and that of the VR simulation part was 20 (SD 4) minutes. In nearly 67% (n=14) of the 21 VR simulations, technical difficulties arose, but all simulations could be completed. The most serious problems were hardware and software related and involved tracking, resulting in incorrect spawn or disconnection from the VR simulation. There was also 1 case of continuous controller vibration. Software-related problems included the patient overstretching his head and not speaking when the hand (or the controller) came too close to his neck. In addition, some VR simulation materials that had been placed on the patient, such as the blood pressure cuff, were no longer attached to the patient after switching to another phase of the simulation (eg, postictal). There were also situations where either the patient's responses were no longer heard by both students or 1 student could no longer hear the other student and the patient. Other issues were reported, but they were not related to technical problems, like blurred vision or double hearing. Students heard the team member through noise-canceling headphones due to the microphone setup (for recording), but also heard others in real time, causing a confusing mix of delayed and overlapping sounds.

Analyses of the questionnaires revealed that students rated both the e-learning and VR simulation parts as contributing well to achieving the learning objectives (median 5, IQR 4 - 5). They also gave the same high grade to both parts (median 5, IQR 4 - 5). The debriefing received similarly high ratings (median 5, IQR 4.8 - 6) and grades (median 5, IQR 5 - 6).

The coding system and some examples of the free-text responses can be found in Multimedia Appendix 4. Overall, there were only a few suggestions for improvement. Suggestions were made on improving the e-learning content, some of which were inconsistent, such as indicating that the e-learning was overloaded versus that it should be expanded. Feedback on the VR simulation pointed to technical limitations and the need for a longer duration. Suggestions for debriefing related to content and structure. Key learning experiences included interprofessional working, teamwork, handover, and the effectiveness of VR as a learning tool. The overall comments covered a range of issues, with some mentioning technical distractions and a preference for more human-like avatars. Some students found the VR experience new and stressful and suggested repetition for better adaptation. Students emphasized the importance of the orientation tour and the need for clear instructions. Again, some students mentioned the duration of the simulation (too short) and that the VR was a valuable learning tool. Some specifically highlighted its effectiveness for team training and the acquisition of standards.

Discussion

Principal Findings

This evaluation study examined the acceptance, learning outcomes, and feasibility of the newly developed INTEAM training course, in which 21 pairs of nursing and medical students trained together their medical and handover skills in a VR simulation. Results of questionnaire analyses and pre- and posttest comparisons indicate that the course was perceived as highly acceptable, feasible, and may be effective in improving handover skills. In the following, we summarize and discuss the principal findings.

Acceptance

The acceptance of the VR simulation as part of the INTEAM training course was measured by usability, VR-induced sickness, sense of presence, subjective workload, user satisfaction, and technology acceptance. The INTEAM training course demonstrated good usability [44], despite a relatively high rating for VR-induced sickness using the SSQ [37]. Previous research suggests that high levels of simulator or VR-induced sickness can lead to reduced usability [49,50]. However, it is possible that the SSQ is not the most appropriate tool for capturing usability in a VR setting, as cybersickness can differ from simulator sickness [45]. Instead, the use of a specific tool such as the Virtual Reality Sickness Questionnaire may provide more accurate results [51]. In both measures, VR-induced sickness and usability, we observed a gender difference, namely that men rated usability higher and reported less VR-induced sickness, and this is consistent with findings from other studies [52,53].

Compared to other studies [54], the workload was judged as fairly high, potentially due to most students being in a VR simulation for the first time. Although some research indicates a lower workload in VR [28], this pertained to single-player skill training without time constraints. Conversely, other studies have noted increased workload under stress [54,55]. Students mentioned that they had felt additional stress due to the unfamiliarity of the VR tool, particularly during the already tense emergency simulation. Nonetheless, despite these challenges, students expressed a high level of satisfaction.

Learning Outcomes

The learning outcomes of the INTEAM training course were assessed through students' performance in structured handover, self-reported confidence level, and their evaluation of the effectiveness of the training. When comparing handover quality before and after the training, we observed a slight improvement in ISBAR-related learning, which is consistent with studies that showed enhanced outcomes when ISBAR training is coupled with simulations rather than solely relying on theoretical instruction [42,56].

At baseline, medical students showed less confidence in interprofessional work than nursing students possibly because the latter had attended more interdisciplinary lectures on various topics. Students' confidence in handling seizure cases increased significantly after the training, probably due to the integration of theory and practice in an authentic yet controlled environment [26]. The positive comments about VR as a learning tool support the assumption that VR is particularly effective for Generation Z students [57].

Feasibility

Feasibility was captured by recording technical aspects such as the duration of the orientation and VR simulation session, any technical problems, and comments from the moderator. In terms of content, students evaluated e-learning, VR simulation, and debriefing using predefined questions and shared their main learning experiences.

We experienced technical difficulties, but most of them were easily resolved with minimal effort. None of the VR simulations had to be terminated due to technical malfunctions. This may be attributed to the presence of a coordinator who was always available and had high technical expertise. Some disturbances, like blurred vision, were attributed to slight movements of the head-mounted displays, although the Elite Strap helped secure them; nevertheless, text in VR was acknowledged as being potentially less clear than in reality. The additional battery in the Elite Strap proved beneficial and ensured that there were no battery-related interruptions during the training sessions.

One issue with the feasibility was the absence of any replacements who could take over if a student failed to appear. This is also a crucial consideration when incorporating such training into a curriculum [58]. There will typically be a larger number of students, and they will need to be divided into smaller groups. One potential approach is to involve several students per session, with some observing while others participate, as they did in other studies [59]. This facilitates a peer-tutor dynamic while ensuring that at least 1 nursing and 1 medical student are present, even if attendance is not consistent.

As indicated by the grading of the participants, the course content seems feasible. Even though there were a few improvement suggestions, some of these were inconsistent. The positive ratings of the learning objectives by both groups lead us to believe that we have successfully developed valuable learning objectives that are not only interprofessional but also individually relevant for each group.

Students expressed positivity toward the interprofessional approach and would appreciate the inclusion of interprofessional training in their curricula. Other studies showed similar findings [60,61].

Strengths and Limitations

The study's key strengths include the development and evaluation of the INTEAM training by an interdisciplinary team comprising experts in medical education, emergency medicine, psychology, and nursing. This ensured a comprehensive and well-rounded approach to the project. Furthermore, the study used validated and widely used tools for assessing VR-specific outcomes, enhancing the reliability and relevance of the findings. The study also adhered to methodological rigor, contributing to the robustness of the results. However, this study has some limitations worth noting. First, due to the study design, such as the absence of a control group and the relatively small sample size, the statistical robustness and generalizability of the results may be affected. While the findings offer valuable initial insights, it is important to note that no causal relationships can be inferred. Second, voluntary student participation might have introduced self-selection bias. Third, the assessment of handover quality as an indicator of learning outcome relied on a single evaluator and thus may have introduced observer bias despite the evaluator's extensive practical experience. Fourth, not varying the order of vignettes between pre- and posttest of handover quality might have limited the assessment's sensitivity. However, the second vignette was recognized by experts as the more challenging one, which further supports the results that suggest an increase in handover performance.

Future Directions

We believe that there should be careful consideration and further research on the implementation of interprofessional training courses that include a VR simulation. It would be beneficial to investigate whether the technical aspects become less prominent when the VR simulation is repeatedly practiced. Once improved software and hardware become available, it will, of course, be worth exploring whether this leads to overall improvements.

Furthermore, different INTEAM training courses should be developed to explore all the learning objectives that can be achieved through such training. In this case, it is essential to select learning objectives that are significant for all involved students such as, in our case, medical and nursing students. Moreover, we need further research that investigates long-term effects and whether students can strengthen their teamwork skills through these courses and derive practical benefits for their future professional lives, as is the case with traditional team training [10].

Conclusions

The INTEAM training course, including a VR simulation in emergency medicine, was well received by the nursing and medical students, and their handover skills and confidence in managing patients with seizure were improved after the course. Although some technical problems occurred during the VR simulations, none resulted in dropout, thus confirming the feasibility of the approach. Technical enhancements and organizational considerations are advisable for further improvement. These promising results encourage the use of VR simulations for team training in the education of nursing and medical students.

Acknowledgments

The authors would like to thank Fabienne Gschwind, Lukas Schwendimann, and Britta Haupt for their invaluable support with preparing and conducting the study. The authors also would like to thank BeLEARN for the funding and for providing the facilities to conduct the pilot study. ChatGPT3.5 was used to edit selected parts of the manuscript to improve the language, and the changes were subsequently reviewed by a native speaker. This project received financial support from BeLEARN, an association established by 5 Bern universities to advance digitalization in education. The content of this scientific paper reflects the authors' views alone and does not necessarily align with those of BeLEARN. The authors are solely responsible for the paper's content, with no implied influence or endorsement by the funder.

Data Availability

The datasets generated during and analyzed during this study are available in the Open Science Framework repository [62].

Authors' Contributions

ANN was involved in acquisition, analysis, interpretation, drafting, and revision. RW was involved in conception, design, acquisition, drafting, and revision. BDR was involved in conception and revision. TCS and JEK were involved in conception, design, interpretation, and revision. TB was involved in conception, design, interpretation, drafting, and revision. All authors have approved the submitted version and have agreed both to be personally accountable for their own contributions and to ensure that questions related to the accuracy or integrity of any part of the work, even ones in which the author was not personally involved, are appropriately investigated and resolved, and the resolution documented in the literature.

Conflicts of Interest

TCS holds the endowed professorship of emergency telemedicine at the University of Bern sponsored by the Touring Club Switzerland. The sponsor has no influence on the research or decision to publish. All other authors have nothing to disclose.

Abstract

Background: Video-based error correction (VBEC) in medical education could offer immediate feedback, promote enhanced learning retention, and foster reflective practice. However, its application in cardiopulmonary resuscitation (CPR) training has not been investigated.

Objective: The objective of this study is to assess whether the VBEC procedure could improve the training performance of CPR among anesthesiology residents.

Methods: A quasi-experimental study was conducted among anesthesiology residents between December 2022 and April 2023. Primary outcomes included a posttraining knowledge test and practical assessment scores. Secondary outcomes included the number of residents who correctly conducted CPR at each step, the rate of common mistakes during the CPR process, and the self-assessment results. A total of 80 anesthesiology residents were divided into a VBEC group (n=40) and a control group (n=40). The VBEC group underwent a 15-minute VBEC CPR training, whereas the control group underwent a 15-minute video-prompting CPR training.

Results: The posttraining knowledge test score of the VBEC group was significantly higher than that of the control group (73, SD 10.5 vs 65.1, SD 11.4; *P*=.002). The residents in the VBEC group had lower error rates in “failure to anticipate the next move” (n=3, 7.5% vs n=13, 32.5%; *P*=.01) and “failure to debrief or problem solve after the code” (n=2, 5% vs n=11, 27.5%; *P*=.01), as well as better performance in the “secure own safety” step (n=34, 85% vs n=18, 45%; *P*<.001) than those in the control group. The VBEC group showed significantly higher confidence in CPR than the control group (n=?, 62.5% vs n=?, 35%; *P*=.03).

Conclusions: VBEC may be a promising strategy compared to video prompting for CPR training among anesthesiology residents.

Introduction

Background

Cardiac arrest remains a significant health care burden despite substantial improvements in survival rates in the past several decades [1]. High-quality cardiopulmonary resuscitation (CPR) is the key link in the chain of survival, and successful CPR may increase the survival rate of patients experiencing cardiac arrest [2,3]. For anesthesiology residents, the likelihood of administering CPR is high, and thus CPR training is of utmost importance [4]. Unfortunately, due to limited training quality and efficiency, the overall quality of CPR remains low, which may further lead to undesired outcomes in clinical practice [5,6]. Thus, CPR instruction modalities are needed to improve the quality of CPR training of anesthesiology residents to maximize their performance.

Video prompting has been shown to be an effective instructional method in the acquisition of a variety of skills, such as vocational. By providing step-by-step guidance and immediate feedback, video prompting can facilitate the development of the necessary skills and confidence in learners required to perform effectively a task [7-9]. Furthermore, emerging evidence suggests that the additional procedure of video-based error correction (VBEC), during which participants who fail to complete a step correctly are interrupted and shown the video prompt again within a short time, can promote skill acquisition more efficiently [10]. VBEC in medical education could offer immediate feedback, promote enhanced learning retention, and foster reflective practice. It allows learners to quickly recognize and correct mistakes, aiding in the memorization of correct procedures through visual demonstration. This method also encourages learners to observe their actions critically, supporting self-improvement and deeper understanding. By providing accessible and consistent instructional content, it ensures equitable learning opportunities. Therefore, introducing the VEBC procedure into CPR training performed with video prompting may enhance the residents' learning efficiency and performance.

Objective

In this study, we hypothesized that VBEC would improve the CPR skills of anesthesiology residents.

Methods

Study Design and Participants

This quasi-experimental study was conducted in the Simulation Teaching Center of Hospital among anesthesiology residents between December 2022 and April 2023. Participants who met all of the following criteria were included: (1) ≥18 years old; (2) anesthesiology residents; (3) attended CPR training sessions; and (4) primary skill levels for CPR. Residents in elective rotations were excluded.

Ethical Considerations

Informed consent was obtained from all residents. Ethical approval was received from the Ethics Committee of Shanghai General Hospital (approval #2022KY115). Written informed consent was obtained from all participants.

Intervention

All residents received a web-based pretest consisting of knowledge and practical assessment based on the Resusci Anne trainer (Laerdal Medical Corporation), with the practical assessment involving the execution of the complete steps of CPR on a manikin. Subsequently, all residents attended a didactic lecture using PowerPoint (Microsoft Corporation) on the American Heart Association (AHA) Guidelines for CPR and Emergency Cardiovascular Care (ECC) [11] and watched a standard CPR video. Then, the residents were divided into VBEC and control groups in the 1:1 ratio.

The training process for the VBEC group was a 15-minute video error correction segment. There were ten CPR video segments with errors in the steps, after which trainees discussed and corrected the errors and practiced the correct steps on a manikin (Multimedia Appendix 1). At the end of each video clip, the trainer announced, "Okay, let's discuss this step." The residents were then given 30 seconds to point out the mistake in the video and perform that step on the Resusci Anne trainer in the correct way. This procedure was repeated for all 10 video clips. Further, all residents received 30-minute hands-on standard CPR training, during which they were asked to perform a complete CPR procedure on the Resusci Anne trainer.

The training process for the control group involved a 15-minute video reinforcement segment. There were ten correct CPR step-by-step video segments, after which trainees were asked to practice the correct steps on a manikin following each segment. Then they were asked to perform that step on the Resusci Anne trainer, one at a time. A 30-minute hands-on standard CPR training, the same as that in the VBEC group, was conducted after the video learning in the control group.

At the end of lessons, all residents were asked to independently complete the web-based knowledge test and practical assessment, with the practical test involving performing the entire CPR process on a manikin. The final practical test of each participant was videotaped for evaluation. Finally, all residents completed a web-based questionnaire for self-assessment regarding their performance and satisfaction in this training.

Outcomes and Measurement

Primary outcomes included the posttraining knowledge test and practical assessment scores. Secondary outcomes were the number of residents who correctly conducted CPR at each step, the rate of common mistakes during the CPR process, and the self-assessment results of the residents after the training.

The practical assessment score was the on-target chest compressions (CCs) indicated by the Resusci Anne trainer, that is, the number of CCs meeting the minimum performance metrics for both CC depth and CC rate. The performance and mistakes of the residents were evaluated by both the Resusci Anne trainer and the human trainers, primarily considering the correct steps of high-quality CPR and the number of common mistakes.

Statistical Analysis

Data were analyzed using SPSS (version 15; SPSS Inc). Percentages with numbers in parentheses are used to present categorical data. Continuous data are expressed as mean (SD). Continuous variables were compared using the Student 2-tailed *t* test. Categorical variables were compared with the χ^2 test. A 2-sided *P* value <.05 was considered to indicate a statistically significant difference.

Results

Baseline Characteristics

Of 83 eligible residents, 80 were subjected to analysis as 3 residents missed part of the training session (Figure 1). The baseline characteristics of the residents are presented in Table 1.

Figure 1. Study flowchart. CPR: cardiopulmonary resuscitation.

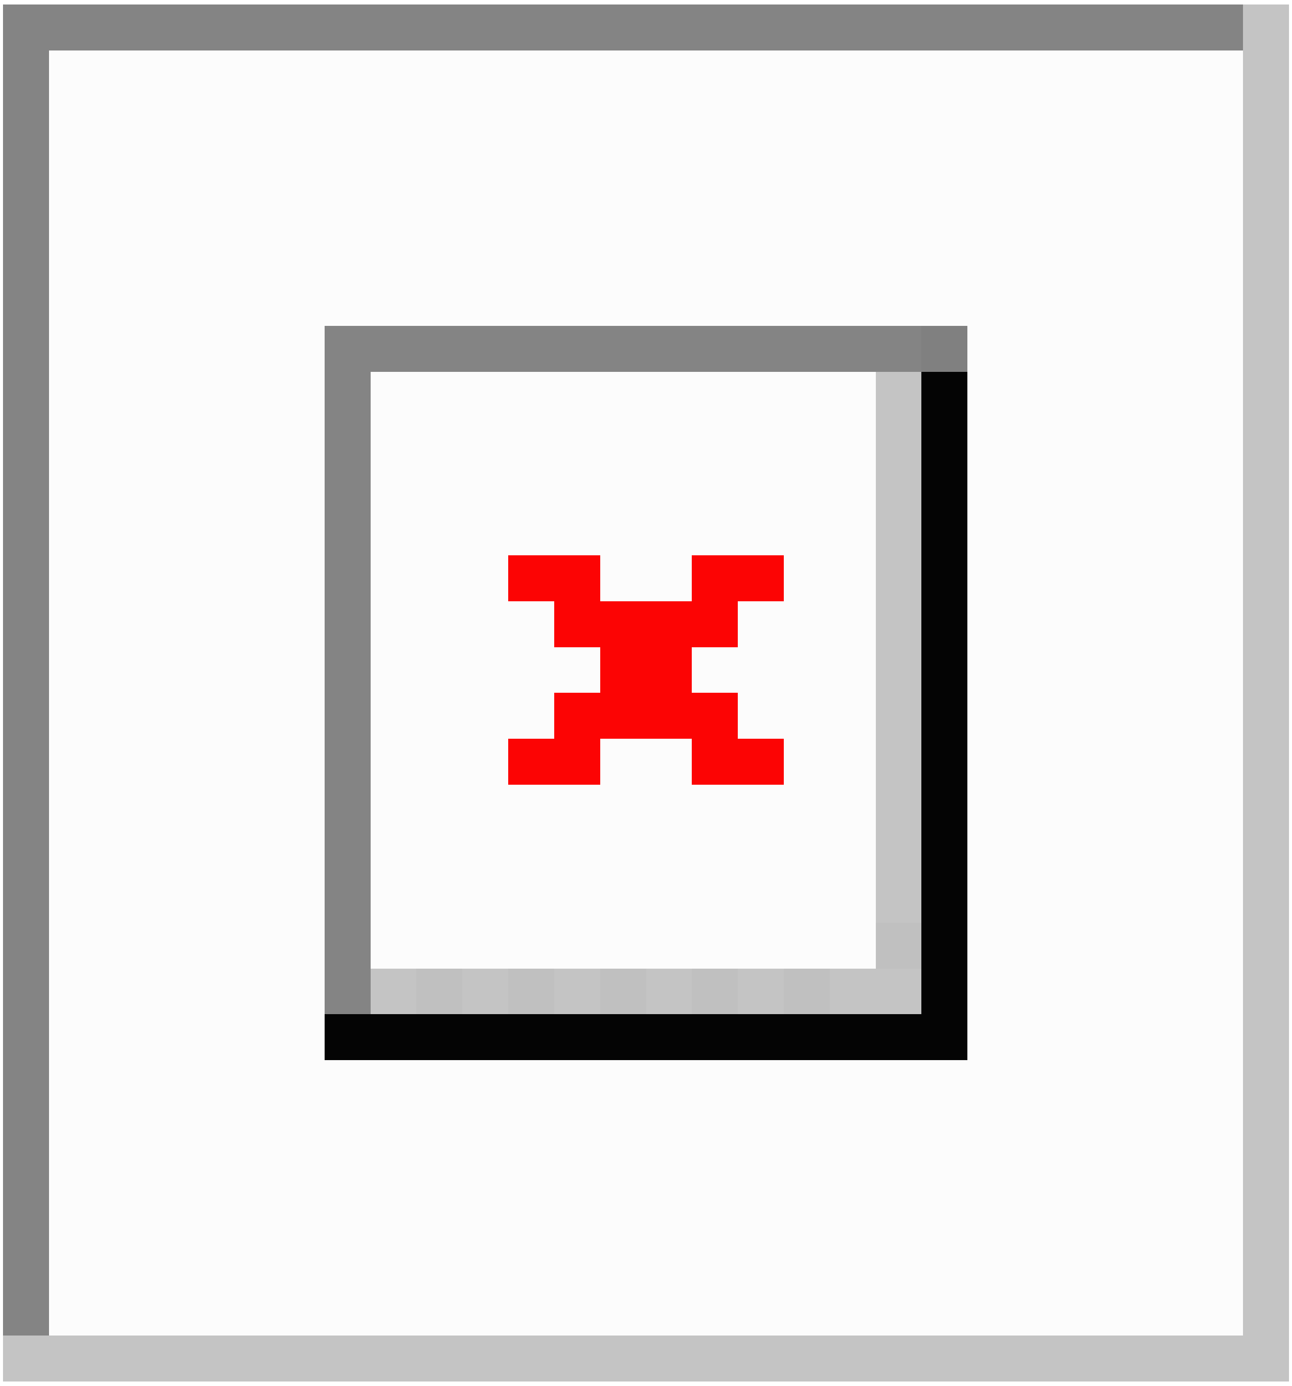

Table . Baseline characteristics (n=80).

Characteristics	VBEC[a] (n=40)	Control (n=40)	*P* value
Age (year), mean (SD)	28 (5)	27 (5)	.45
Male, n (%)	20 (50)	22 (55)	.83
Doctors with postgraduate degrees, n (%)	22 (55)	24 (60)	.66

[a]VBEC: video-based error correction.

Primary Outcome Results

The pretraining theoretical score (63.9, SD 10.7 vs 63.4, SD 11.6; *P*=.85) and practical scores were comparable between the two groups (81.5 , SD 8.5 vs 82, SD 11.7; *P*=.82). The mean posttraining theoretical score of the VBEC group was significantly higher than that of the control group (73, SD 10.5 vs 65.1, SD 11.4; *P*=.002). No significant difference in the posttraining practical scores was observed between the two groups (86.9, SD 8.8 vs 86.3, SD 9.9; *P*=.77) (Table 2).

Table . Knowledge test score and practical assessment score before and after the training between the VBEC[a] and control groups.

	VBEC (n=40)	Control (n=40)	*P* value	*t* (*df*)	95% CI	Effect size
Knowledge test score, mean (SD)						
Before training	63.9 (10.7)	63.4 (11.6)	.85	0.190 (78)	−4.490 to 5.440	.043
After training	73 (10.5)	65.1 (11.4)	.002	3.228 (78)	3.028 to 12.772	.722
Practical assessment score, mean (SD)						
Before training	81.5 (8.5)	82 (11.7)	.82	−0.229 (78)	−5.082 to 4.032	.051
After training	86.9 (8.8)	86.3 (9.9)	.77	0.299 (78)	−3.537 to 4.787	.067

[a]VBEC: video-based error correction

Secondary Outcome Results

In the stepwise comparison of CPR performance, performance for the "Secure own safety" step was significantly higher in the VBEC group (85% vs 45%; *P*<.001). Among the common mistakes, residents in the VBEC group showed a lower error rate of "failure to anticipate the next move" (7.5% vs 32.5%; *P*=.01) and "failure to debrief or problem solve after the code" (5% vs 27.5%; *P*=.01) than the control group (Table 3).

Table . Comparison of correct performance and common mistakes of cardiopulmonary resuscitation between the VBEC[a] and control groups.

	VBEC, n (%)	Control, n (%)	*P* value
Alert emergency services	34 (85)	36 (90)	.74
Recognize illness/injury	40 (100)	40 (100)	>.99
Secure own safety	34 (85)	18 (45)	<.001
Examine patient	34 (85)	30 (75)	.40
Recovery position	36 (90)	38 (95)	.68
Decide if CPR[b] should be started	38 (95)	32 (80)	.09
Effective chest compressions	38 (95)	35 (87.5)	.43
Open the airway and check breathing	37 (92.5)	36 (90)	>.99
Give rescue breaths	40 (100)	38 (95)	.49
Check rhythms and resume CPR	39 (97.5)	35 (87.5)	.20
Failure to recognize arrest	2 (5)	3 (7.5)	>.99
Failure to act (or act rationally) and failure to call for help appropriately	2 (5)	8 (20)	.09
Failure to provide effective compressions	2 (5)	5 (12.5)	.43
Failure to provide effective ventilations for the patient	0 (0)	1 (2.5)	>.99
Failure to anticipate the next move	3 (7.5)	13 (32.5)	.01
Failure to debrief or problem solve after the code	2 (5)	11 (27.5)	.01

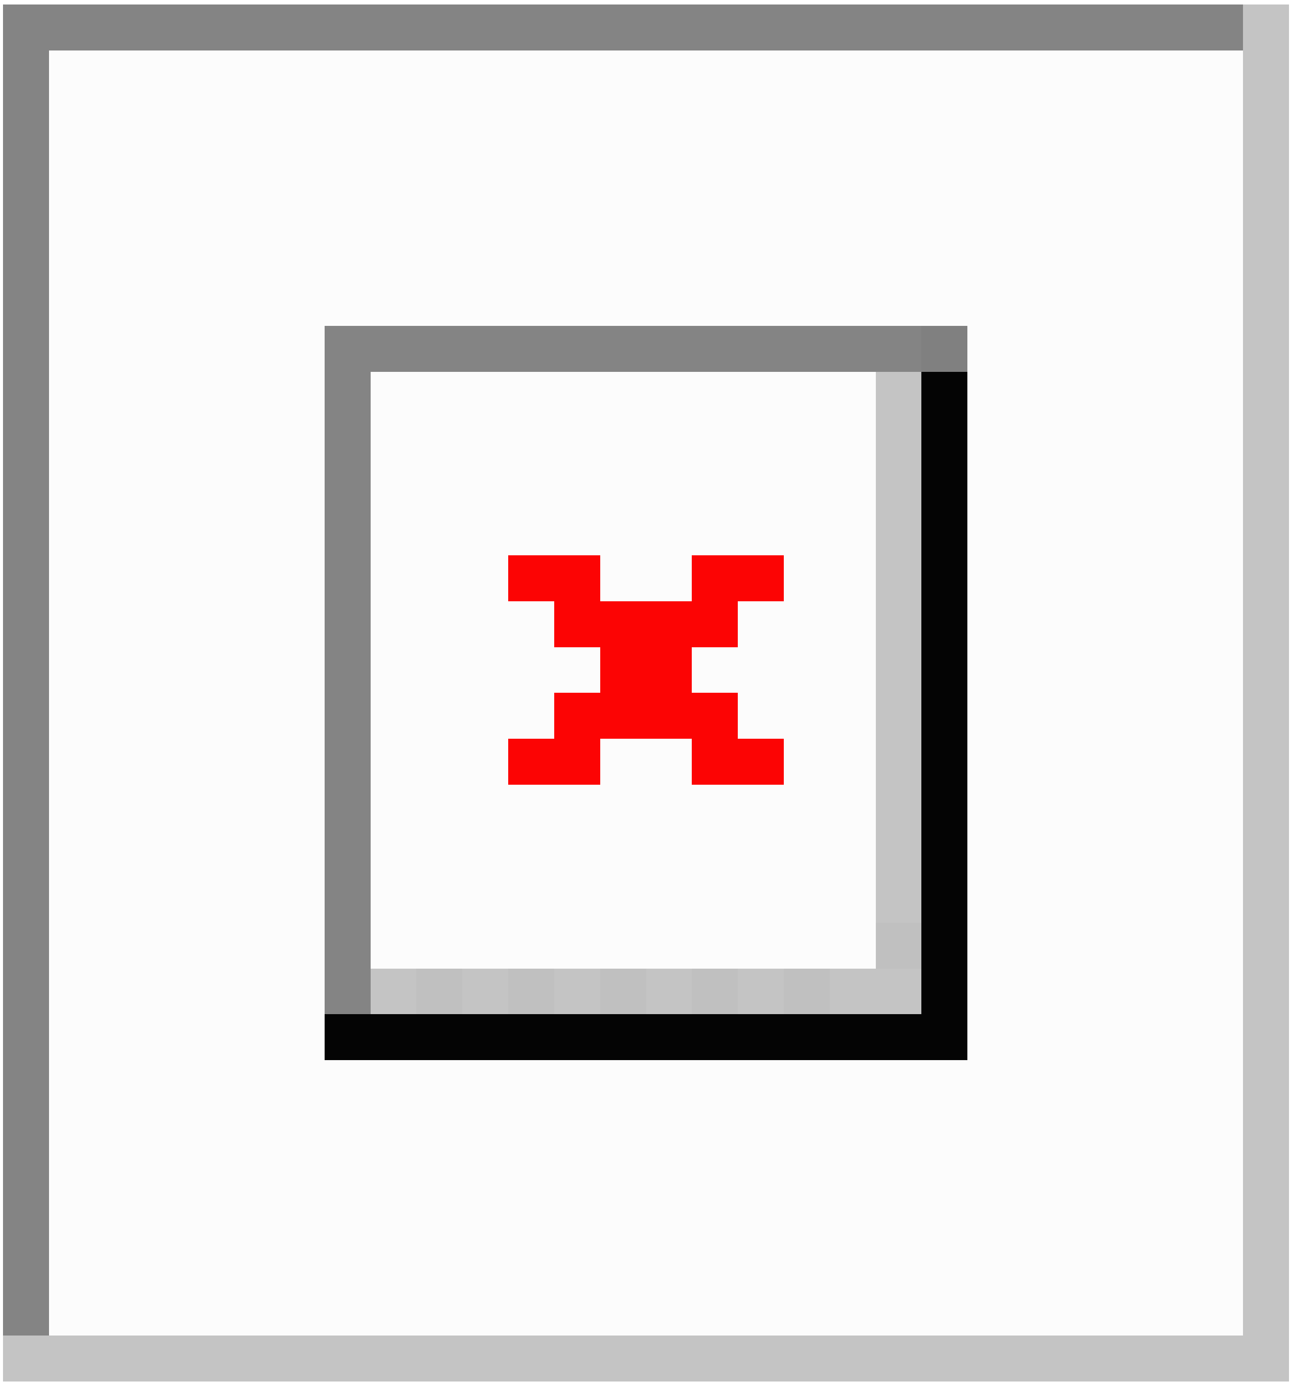
[b]CPR: cardiopulmonary resuscitation.

Performance After Training

The residents' perceptions after the training regarding self-assessment of their performance and related experiences are presented in Figure 2. The residents in the VBEC group had significantly higher confidence in CPR than the control group (n=?, 62.5% vs n=?, 35%; *P*=.03).

Figure 2. Participants' positive reactions to activities (%). VBEC: video-based error correction. Asterisk indicates statistical significance.



Discussion

Principal Findings

In this study, it was revealed that VBEC improved the quality of CPR training of anesthesiology residents. Specifically, the VBEC-trained residents had improved posttraining theoretical scores, a lower error rate for common mistakes, and better performance at certain steps of the CPR procedure compared with the control group. The residents who received the VBEC training also showed higher confidence in performing basic CPR than the control group. These findings suggest that VBEC may be applicable in anesthesiology residents' training.

Comparison to Prior Work

High-quality CPR can dramatically increase the chances of survival in cardiac arrest. The AHA CPR Guidelines emphasize that to bridge the gap between knowledge and practice, educators should develop a method for improving CPR education [12,13]. Errorless, or near-errorless, learning procedures involve attempting to prevent errors during all teaching sessions [14]. A video prompting technique is to begin teaching with the most assistive prompt to minimize the likelihood of an error [15]. Error correction, on the other hand, involves procedures that are employed following an incorrect response that would increase the probability of a correct response on subsequent trials [16]. Previous research has evidenced the effectiveness of the error correction procedures and has confirmed their benefits [15,17-20]. In this study, we used "error correction learning" as the primary method to improve CPR education and optimize the studying experience. VBEC may provide the learners with the opportunity to think and respond independently to the situation before external instructions are given, which may deepen their understanding of the CPR procedure. This approach may explain the improvement in the posttraining knowledge test among residents in the VBEC group. While some studies argue against the use of error correction since this may cause trainees to pick up incorrect information [21], this study does not support such a conclusion since none of the outcomes of the VBEC group were inferior to those of the control group. On the contrary, the VBEC group had a lower chance of making mistakes that are common in CPR procedures and paid more attention to the rescuer's safety. Therefore, the VBEC may highlight the error-prone points in standard CPR training. Moreover, Goodson et al demonstrated that VBEC is effective for learners who do not fully benefit from video prompting, as all participants achieved 100% accuracy in task analysis. This outcome was noteworthy, especially since the study included individuals with developmental disabilities [10]. Considering the group-based nature of medical education, this suggests that VBEC could be a valuable tool in the training of medical residents.

Strengths

No difference was found between the VBEC and the control groups in practical performance after the training. This result may be attributed to the fact that on-target CCs were used to evaluate the practical performance; CC is a muscle memory-based skill that requires more physical practice. However, the 15-minute VBEC or video prompt training plus the 30-minute hands-on training is relatively short for substantially improving the practical performance of the residents. Nevertheless, CC is a central but not the only key part of the whole CPR procedure. Successful CPR in real situations also relies on non-technical skills, such as fluency in the CPR code and physicians' self-confidence [22,23]. Our results showed that the VBEC group had a lower error rate and higher self-confidence in conducting CPR. More specifically, the fewer "failure to anticipate the next move" in the VBEC group may indicate an enhanced fluency throughout the CPR code. These improvements are essential for the improvement of the overall CPR quality, even with the same CC.

Limitations

This study is not without limitations. First, the small sample size limits the generalizability of the results, indicating a need for future studies with larger populations to confirm these findings. Second, the brief duration of the testing period suggests the necessity for extended follow-up to fully understand the long-term implications. Third, further investigation is required to explore how VBEC may be applied to improve practical skills such as CC. Moreover, the study's design constraints, including the absence of power estimation, rigorous randomization, and blinding, hinder our ability to draw definitive causal conclusions, warranting a cautious interpretation of the results.

Conclusions

In summary, VBEC may be an efficient teaching technique used in CPR training, not only for improving residents' cognitive performance and self-confidence but also for increasing the rate of completion in providing a fluent CPR sequence with fewer mistakes. However, further research with longer-term follow-up periods is needed to determine whether error correction learning improves long-term outcomes.

Data Availability

The dataset supporting the results of this work is included in the article.

Authors' Contributions

YW and JF conceived and coordinated the study; designed, performed, and analyzed the study; and wrote the paper. SW, HW, WG, and LH carried out the data collection, data analysis, and revised the paper. All authors reviewed the results and approved the final version of the manuscript.

Abstract

Background: Knowledge construction in the context of children's science education is an important part of fostering the development of early scientific literacy. Nevertheless, children sometimes struggle to comprehend scientific knowledge due to the presence of abstract notions.

Objective: This study aimed to evaluate the efficacy of augmented reality (AR) games as a teaching tool for enhancing children's understanding of optical science education.

Methods: A total of 36 healthy Chinese children aged 6-8 years were included in this study. The children were randomly divided into an intervention group (n=18, 50%) and a control group (n=18, 50%). The intervention group received 20 minutes of AR science education using 3 game-based learning modules, whereas the control group was asked to learn the same knowledge for 20 minutes with a non-AR science learning app. Predict observe explain tests for 3 topics (animal vision, light transmission, and color-light mixing) were conducted for all participants before and after the experiment. Additionally, the Intrinsic Motivation Inventory, which measures levels of interest-enjoyment, perceived competence, effort-importance, and tension-pressure, was conducted for children after the experiment.

Results: There was a statistically significant difference in light transmission (z=−2.696; P=.008), color-light mixing (z=−2.508; P=.01), and total predict observe explain test scores (z=2.458; P=.01) between the 2 groups. There were also variations between the groups in terms of levels of interest-enjoyment (z=−2.440; P=.02) and perceived competence (z=−2.170; P=.03) as measured by the Intrinsic Motivation Inventory.

Conclusions: The randomized controlled trial confirmed that the AR-based science education game we designed can correct children's misconceptions about science and enhance the effectiveness of science education.

Introduction

Children's level of scientific concept generation is representative of their inquiry, comprehension, and application of natural events and phenomena and reveals their cognitive capacities and developmental stages [1]. Knowledge construction in children's science education contributes to early scientific literacy development, which improves children's cognitive level by enhancing thinking skills, and is being emphasized by scholars and parents [2]. Traditionally, children build domain knowledge in science through films, literature, and lectures in science education [3]. Although some forms of educational learning are accessible, they often uses a monotonous instructional format, and confusing content hinders the transmission of scientific knowledge [4].

Serious games provide a more engaging interactive environment and an accessible cognitive framework to facilitate effective learning [5]. Studies have shown that serious games have more effective learning outcomes than traditional methods of science education (eg, face-to-face lectures and book-based knowledge transfer) [6,7]. It is suitable for children's investigation of natural phenomena because the game's visual design simulates paranormal phenomena that cannot be produced in real life. Lester et al [8] constructed virtual environments that generate natural phenomena, allowing children to assume roles in open-world environments and to freely rely on their knowledge of the geography and biology of natural environments. Laine et al [9] permitted children to interact with hosts in virtual narrative game scenarios and to investigate the geometry of the virtual environment with the protagonist. The concept of light, a prevalent natural phenomenon, was selected as the subject of this research to explore its design for enhancing children's cognitive abilities. Optical science education programs are still presented in a 2D format, which has been demonstrated to be ineffective [10].

Due to the spatial complexity and abstract nature of optics, it is challenging to accurately convey knowledge through flat visual representations [11]. Therefore, it is necessary to blur the boundaries between the 3D real world and the 2D digital world to reduce the distance between children's learning of science concepts and their learning environments [12]. 3D representations and interactions in augmented reality (AR) games have the potential to enhance spatial cognition, thereby facilitating children's comprehension of spatially abstract scientific concepts [13], such as simulating the movement of the sun in a classroom environment [14]. Sahin and Yilmaz [15] demonstrated that students who used AR technology to improve their science literacy performed better on tests than those who learned using traditional methods. This is as a result of AR technology's ability to enhance the dynamic potential of human consciousness to comprehend the science learning process [16]. In addition, motivational improvement was mentioned as one of the frequently observed AR outcomes [17]. Using AR apps increased student motivation relative to other instructional aids [18]. Our study investigated whether designing optical science education with more comprehensible 3D interactions for children can enhance science education and promote children's motivation.

The study designed the "AR Serious Game for Optical Science" and conducted a randomized controlled trial to determine the efficacy of this AR game product in enhancing children's science education. The primary objective of this study was to validate the efficacy of AR science education games for children; the secondary objective was to investigate the intrinsic motivation of children toward them.

Methods

Study Design

Guardians of children with independent mobility provided informed written consent for their participation in the study. Participants were randomly assigned to the intervention and control groups using a randomization list, which was maintained by members of the study group uninvolved in any other aspect of the study. Participants' guardians received and opened opaque, sealed envelopes containing group assignments following the initial evaluation. The evaluator in charge of assessing the results of the AR science education course had no access to participant information or group assignment.

Sample size calculations were performed using PASS software (NCSS LLC) based on the predict observe explain (POE) test scores from the preintervention questions. Group sample sizes of 18 and 18 achieve 90.118% power to reject the null hypothesis of equal means, when the population mean difference is $\mu1 - \mu2 = 3.2 - 1.0 = 2.2$, with SDs of 2.0 and 1.9 for the 2 groups and with a significance level (α) of .05 using a bilateral, 2-sample, equal-variance, 2-tailed *t* test.

Participants

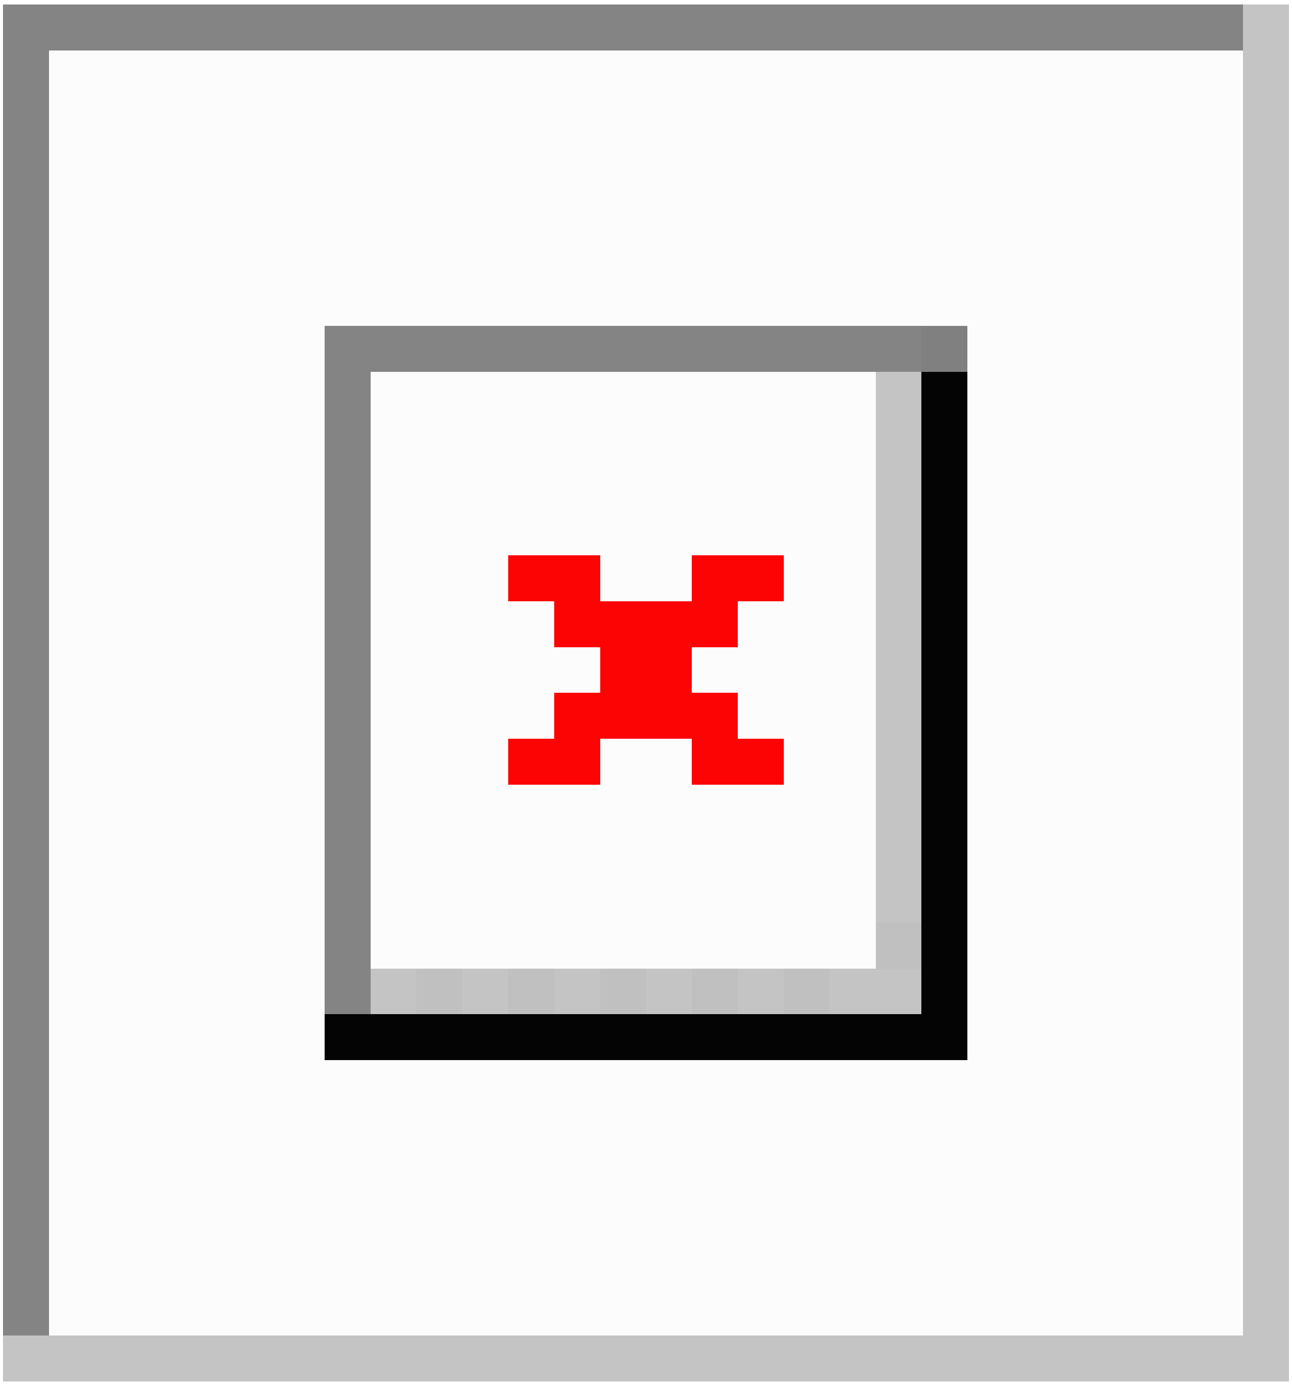
A total of 36 Chinese children (aged 6-8 y) were recruited from Jiangyin Children's Education Center and Jiangyin Wuxi Community in Jiangsu Province and divided into the intervention (n=18, 50%) and control (n=18, 50%) groups.

AR Science Education Game Design

During the learning phase, children are required to engage in physical activities, such as walking around with a handheld device, to interact with the AR scene's content to discover what is unique about the light phenomenon. When children touch the interactive points, the content is explained by animation and voice-overs. This study developed several interactive approaches for children within AR games, such as through in-game visual representations, speech, and interactive methods, which permit children to connect game content to unfamiliar information as they explore. The advantages are as follows: (1) children can use more familiar physical activities with light concepts to establish metaphorical mappings related to orientation, not just gestural touch; (2) rendering light with 3D attributes in the real world reduces the cognitive load generated by children's linkage of abstract knowledge and the real phenomena; and (3) adding various kinds of digital augmentation effects in the AR scene helps children understand the concepts. The project created 3 games based on the characteristics of scientific understanding (Multimedia Appendix 1 and Figure S1 in Multimedia Appendix 2 [9,14,19-28]).

Game 1 introduces children to the fundamentals of animal vision (Figure 1). Animal vision concepts are investigated through AR scenes. By clicking on the icons in the lower-left corner, the game transforms to an animal simulation. In each scenario, a voice-over narration instructs children to identify the visual differences between the animal and the human. When the handheld device is trained on a specific target, a voice-over narration and feedback animation will play.

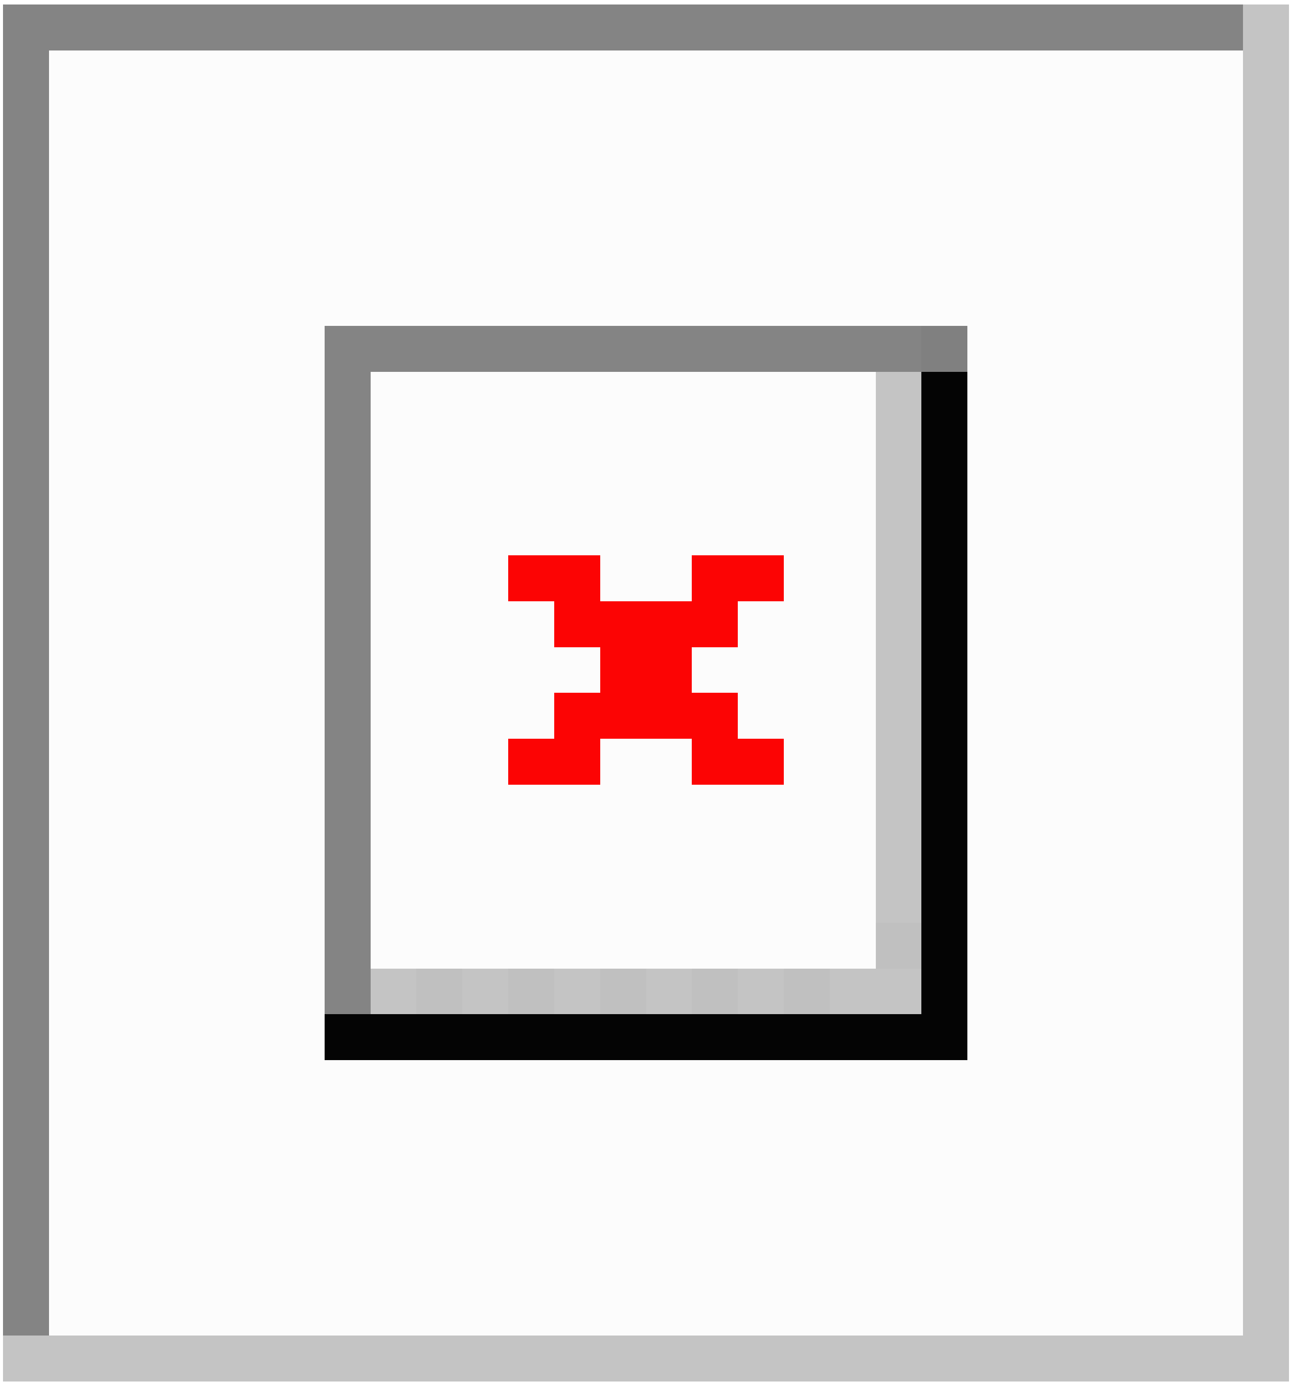
Figure 1. Animal vision augmented reality (AR) game introduction.



In the design of the interaction mode, 3 display modes were established for the game's interactive elements: far, medium, and near (hybrid camera mode). The concept of invisible light is introduced to children in greater detail based on the ray distance between the device's camera and the target element. The far view provides children with an intuitive impression of the invisible light's overall effect; the medium view uses transition animation to illustrate the invisible light's characteristics; and the near view uses special effect particles to illustrate the invisible light's trajectory.

Game 2 introduces children to light transmission–related concepts (Figure 2). In the AR scenario, children navigate the environment with a handheld device and activate energy panels by interacting with flat mirrors and optics. By targeting AR-enhanced prop objects and manipulating the angle of light emission to investigate how light propagates, voice-over explanations and feedback animations are activated.

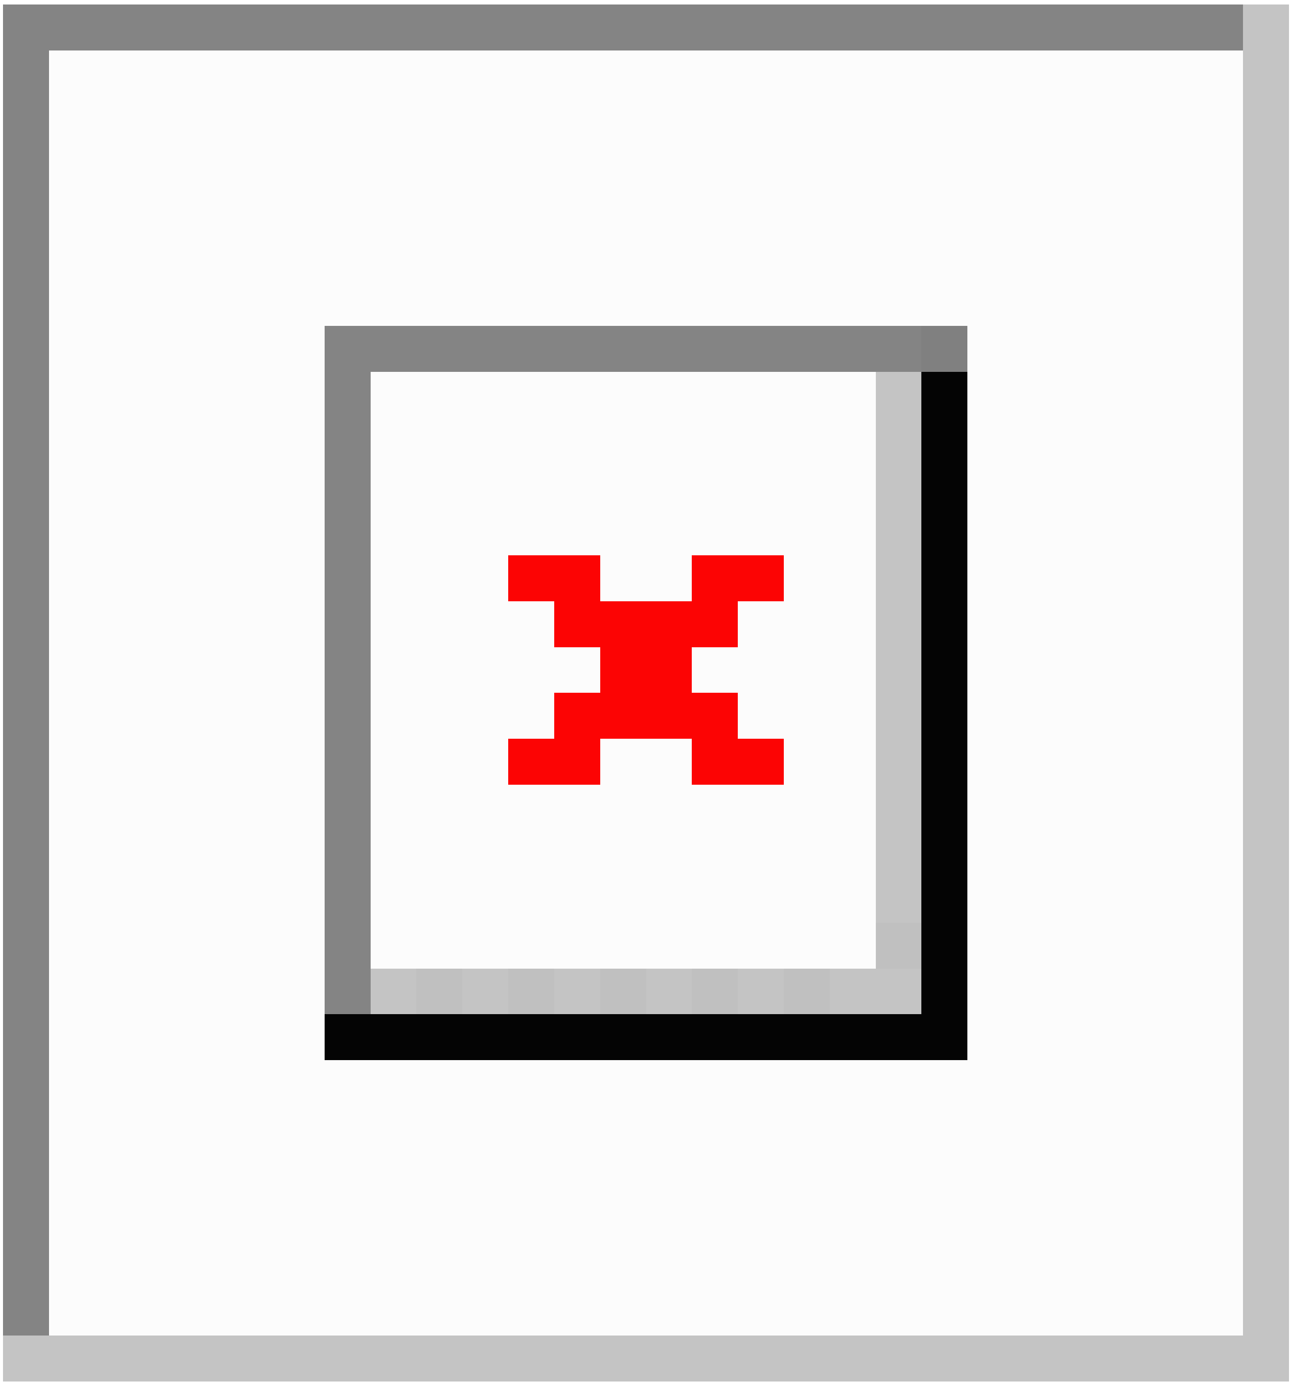
Figure 2. Light transmission augmented reality (AR) game introduction.



According to the voice-over prompts, children can hold the device and manipulate the flashlight from a first-person perspective (spatial exploration mode) as part of the interactive design. They then complete 3 steps: locating the interactive elements (mirrors, ice crystals, etc), adjusting the flashlight's tilt angle, and using the flashlight to complete the light-up task. The progression encourages children to investigate the principles of light transmission through the game.

Game 3 introduces children to color-light mixing concepts (Figure 3). Children were instructed to walk around with the device in hand and explore the color changes of props such as AR-enhanced birds, which are illuminated with various colors of lights. Collecting the target color's shadow initiates a voice-over explanation and feedback animation.

Figure 3. Color-light mixing augmented reality (AR) game introduction.



Regarding the interactive design, children need to hold the device to illuminate the creatures and cast shadows on the present wall, and then they need to press the button to turn the light on and off (projection irradiation mode). The objective of the game required children to perform single-color illumination, 2-color mixing, and 3-color mixing to achieve the desired hue. In another vibrant nursery game, children were instructed to move plants to receive various colors of light and to observe the plants' root elongation and leaf dispersal.

This game design used Unity 3D (Unity Technologies) as the development engine, and the app was installed on an Apple iPad (2018) with a screen resolution of 2048×1536 (264 pixels per inch). The AR component made use of the Vuforia AR SDK (Parametric Technology Corporation) to accomplish the fundamental duties of plane identification and virtual object generation. The interaction section used lens focus to determine the interactions; when the device camera's output rays collide with the target virtual object and the distance is close, it is deemed to have located the target effectively. To imitate the illusion of invisible light, Unity's *Post Processing* module was applied to the camera filter. The principle entailed presenting the camera screen into the buffer of Unity and applying filters and effects prior to displaying it; it can be applied to both the camera screen and the virtual item.

Procedure

This experiment was a randomized controlled trial, and the participants were randomly separated into the intervention group and the control group. The random numbers were generated by applying the SAS software analysis system (SAS Institute) on a computer simulation, and no experimental group was allowed to be selected at random. Every child was tested in the company of a guardian and 2 researchers.

The independent variable was the type of game (an optical science education app called "Light and Color" or the AR game we designed; see Figure S2 in Multimedia Appendix 2 for a comparison of the differences between the 2 games). The dependent variables for both intervention and control group participants were the differences between the pre- and posttest results of the POE tests and the children's motivation to play the game. To create control variables for the experiment, both games included the topics of animal vision, light transmission, and color-light mixing, and neither game involved a human teacher. In addition, there were no significant sex (P=.49) or age (P=.67) differences between the 2 groups.

Intervention Group

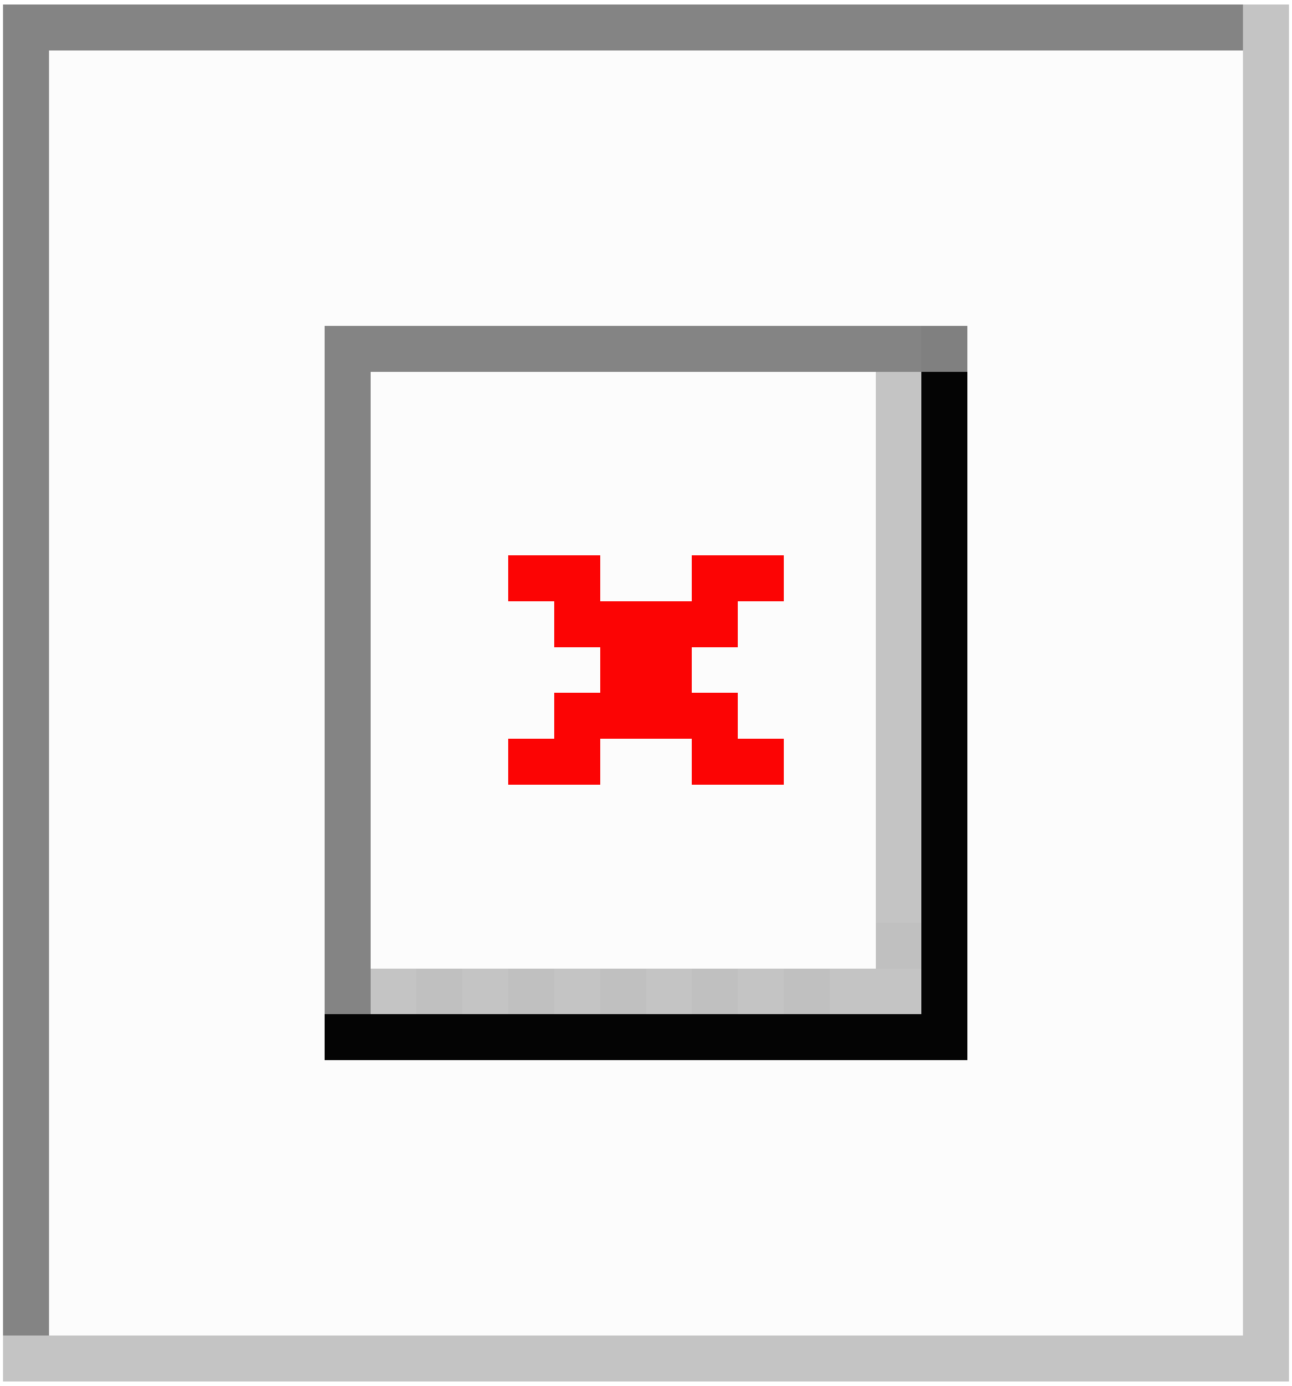
Before the test started, the researcher provided the basic information of the experiment to the participants, including the test topic, test technique, test time, and other information. The participants were asked to complete a cognitive exam on the notion of light and perform a POE test for each topic to find out how well they comprehend the content, without being told whether their answers were correct.

After completing the pretest, intervention group participants were instructed to complete the 3 game-based learning modules of the AR science education app on the iPad regarding animal vision, light transmission, and color-light mixing. On their initial encounter with the game, respondents were given around 10 minutes to comprehend its mechanics. The intervention group's total learning time was limited to 20 minutes, the testing process was completed under the supervision of the instructor and the experimenter, and the children's behavioral characteristics were recorded. During the experiment, the participants were not disturbed in any way; researchers only intervened when they faced difficulties or requested assistance. The participants were given a 15-minute respite at the conclusion of the trial to take another POE test. Before and after the experiment, each participant's performance on the game was recorded. The researcher then read aloud and described the items on the intrinsic motivation and cognitive load scales to the participants, who scored the scale items using a 5-point "smiley face" scale.

Control Group

The control group was also introduced to the experiment and given a preintervention POE test to assess their prior knowledge of the learning material. The control group completed the same 3 game courses for a maximum of 20 minutes using the non-AR app "Light and Color" after completing the pretest. The participants took a 15-minute break at the conclusion of the trial to complete another POE test and the Intrinsic Motivation Inventory (IMI) scale (Figure 4).

Figure 4. Photos of the experimental process: (A) the process of using the augmented reality (AR) game for participants in the intervention group; (B) the process of using the "Light and Color" app game for participants in the control group, and (C) the process of filling out the questionnaire by the participants.



Evaluation Metrics

The study was validated based on several experiments.

The POE test is commonly used in science classes and tries to expose students' expectations about certain events and the rationale for these predictions [29]. It is used to demonstrate scientific experiments to pupils and is advantageous for fostering children's critical thinking and assessing students' grasp of scientific topics. The investigator then displays the relevant physical events to the students using basic prop materials after requiring the students to independently determine the correct answers to the questionnaire along with their justifications. Finally, students are instructed to alter or supplement their explanations in light of the observations. Since children may appear to be able to answer the question properly but not comprehend the reasoning behind it, for each topic, it is possible that they do not comprehend the underlying concept. In this study, individuals' accurate answers and explanations were recorded, and different situations were rated differently based on a 2-tier test [30] (Table 1). This scoring method is frequently used to evaluate students' conceptual understanding [31]. The outcomes were categorized as correct answer+correct explanation, correct answer+incorrect explanation, incorrect answer+correct explanation, and incorrect answer+incorrect explanation. Each topic's overall score was included in the subsequent analysis. To avoid disruptions caused by children's memorization of answers, the experimental posttest questionnaire in this study was different from the pretest questionnaire but was founded on the same scientific concepts. The examination topics are provided in Table S1 in Multimedia Appendix 2.

Table . Two-tier test assessment criteria.

Level of conceptual understanding	Score
Correct answer+correct explanation	2
Correct answer+incorrect explanation	1
Incorrect answer+correct explanation	1
Incorrect answer+incorrect explanation	0

Due to the young age of the study participants, the simplified version of the IMI adapted by Vos et al [32] was selected for this research. It was developed under game conditions with 3 subscales: interest-enjoyment, perceived competence, and effort-importance, to assess the perceived levels of motivation, enjoyment, and perceived difficulty of the participants. To investigate the negative emotions of children using the AR game, the study inserted questions from the original scale's tension-stress section [33] (Table S2 in Multimedia Appendix 2). Participants were asked to rate the extent to which they concurred with the statement using a 5-point Likert scale depicting 5 smiling faces. A score of 5 indicated that the child participant strongly agreed with the statement. To minimize the effect of differences in reading ability, the researcher read the questionnaire audibly to the child participants, who then completed the questionnaire independently.

Ethical Considerations

The study was approved by the Human Research Ethics Committee of Shanghai Jiao Tong University (H2022041I) in China. Informed consent was signed by guardians and the data were deidentified. A toy with a value of CNY ¥50 (US $7.01) was provided as compensation.

Results

A total of 36 healthy Chinese children aged 6-8 years were recruited in May 2022, including 22 male and 14 female children, all of whom participated in the experiment with the consent of their guardians and of their own volition. The 36 participants were randomly assigned to the intervention group (n=18, 50%) and the control group (n=18, 50%), with the mean age of the intervention group being 7.16 (SD 0.76) years and that of the control group being 7.06 (SD 0.78) years. Baseline demographic data and POE test scores for the intervention and control groups are shown in Table 2. The statistical analysis revealed that there was no statistically significant distinction observed between the 2 groups across all variables (all *P*>.05). This suggests that the intervention and control groups exhibited a similar overall comprehension level prior to the commencement of the trial. The experimental procedure is provided in Figure 5.

Table . Baseline data for the intervention and control groups.

Variable	Intervention group[a] (n=18)	Control group[b] (n=18)	*z* score or chi-square (*df*)	*P* value[c]
Male sex, n (%)	10 (56)	12 (67)	0.467 (1)[d]	.49
Age (y), mean (SD)	7.17 (0.76)	7.06 (0.78)	−0.421[e]	.67
POE[f] test score for animal vision, mean (SD)	1.83 (1.10)	1.94 (1.21)	−0.296[e]	.77
POE test score for light transmission, mean (SD)	2.83 (1.72)	2.67 (2.20)	−0.437[e]	.66
POE test score for color-light mixing, mean (SD)	1.50 (1.09)	1.94 (1.16)	−1.031[e]	.30
Total POE test score, mean (SD)	6.17 (2.28)	6.56 (2.12)	−0.273[e]	.78

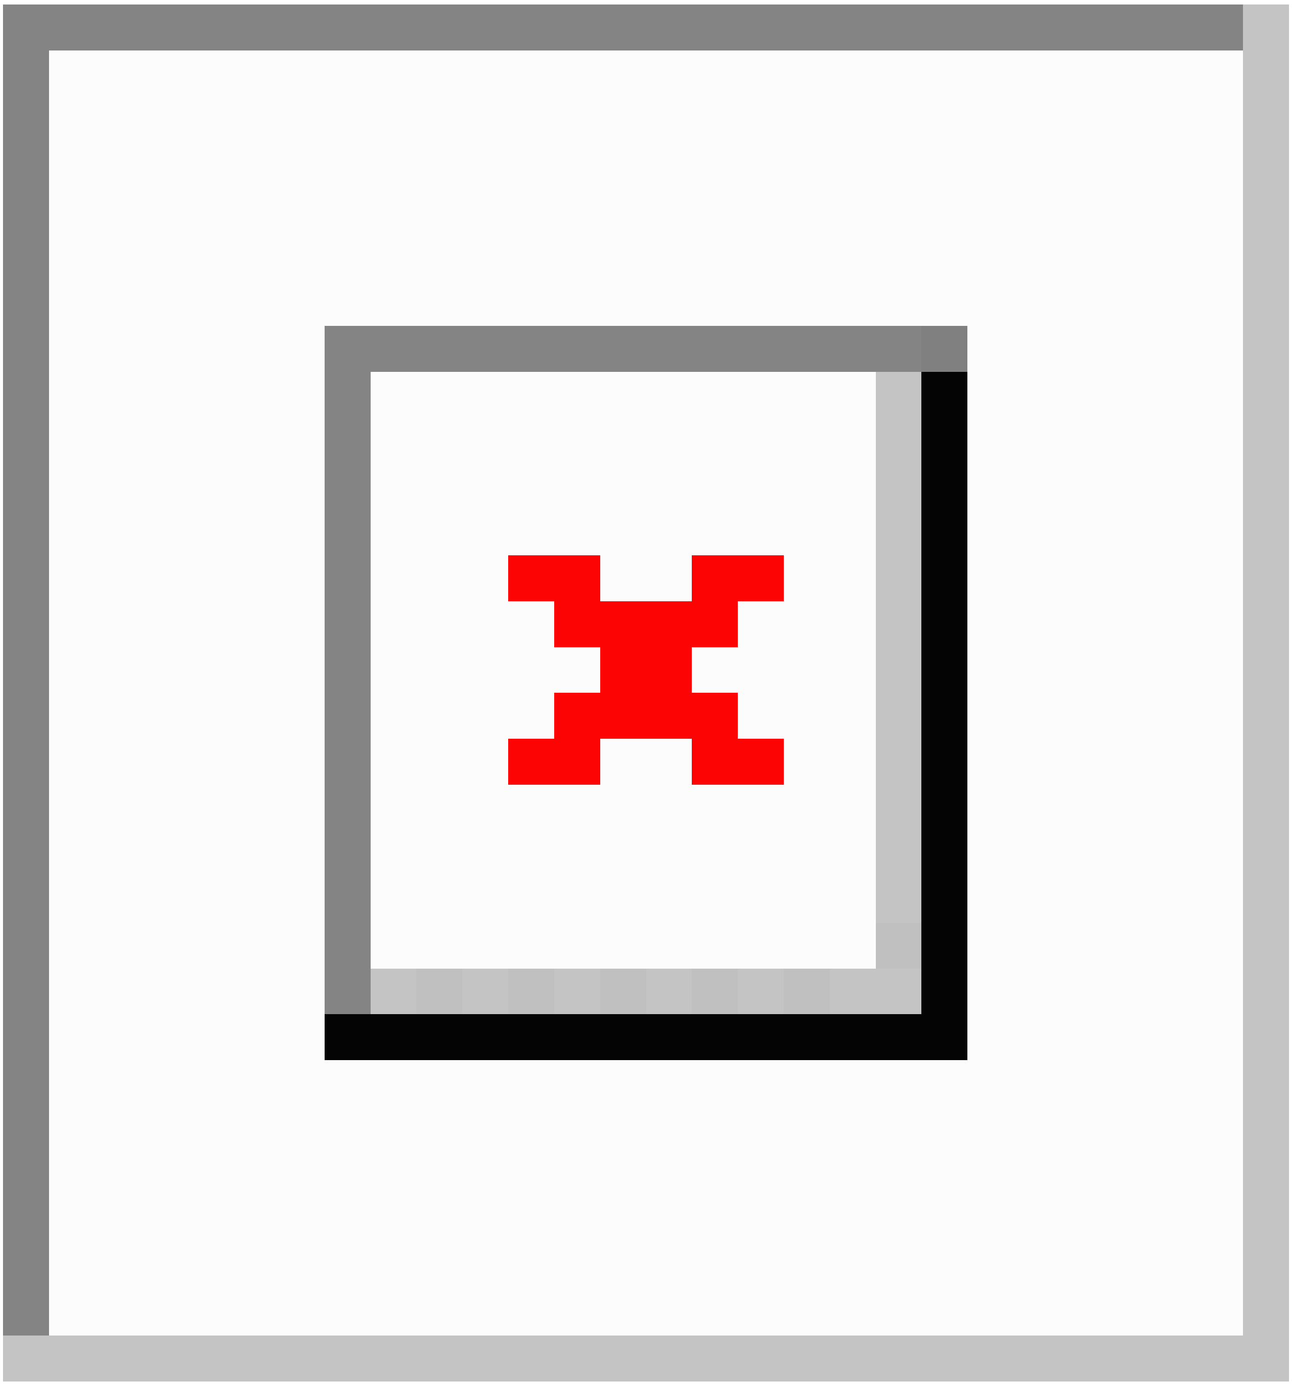
[f]POE: predict observe explain.

Figure 5. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. AR: augmented reality; IMI: Intrinsic Motivation Inventory; POE: predict observe explain.



The results of the normality test revealed a nonnormal distribution of the data (Table S3 in Multimedia Appendix 2). Consequently, the researchers conducted a paired-sample Wilcoxon rank sum test to compare the pre- and posttest findings of the intervention and control groups to assess any differences between the 2 groups. The results shown in Table 3 demonstrate notable fluctuations in both light transmission (z=−2.696; P=.008) and total POE test scores (z=−2.458; P=.01). Nevertheless, the results of the study indicate that there was no statistically significant advantage observed in animal vision (z=−0.847; P=.42) and color-light mixing POE test scores (z=−0.782; P=.46) as a result of the AR game intervention. It should be noted, however, that there was an improvement in scores following the intervention.

Table . Between-group differences between the intervention and control groups on each of predict-observe-explain (POE) test (pre- and posttests).

POE test score		Intervention group[a] (n=18), mean (SD)	Control group[b] (n=18), mean (SD)	Difference, mean (95% CI)	z score	P value[c]
Animal vision				0.36 (−0.71 to 1.43)	−.847	.42
	Pretest	1.83 (1.10)	1.94 (1.21)			
	Posttest	2.33 (1.14)	2.17 (0.99)			
Light transmission				0.97 (−0.37 to 2.31)	−2.696	.008
	Pretest	2.83 (1.72)	2.67 (2.2)			
	Posttest	4.44 (1.76)	3.00 (1.88)			
Color-light mixing				0.72 (−0.44 to 1.88)	−0.782	.46
	Pretest	1.50 (1.09)	1.94 (1.16)			
	Posttest	2.39 (1.24)	2.50 (1.04)			
Total				2.06 (−0.1 to 4.22)	−2.458	.01
	Pretest	6.17 (2.28)	6.56 (2.12)			
	Posttest	9.17 (2.48)	7.67 (1.71)

[b]Non–augmented reality game.

[c]Mann-Whitney *U* test.

In this study, subjective IMI scale values acquired during the trial were statistically analyzed. It was observed that the different groups showed significant variability in levels of interest-enjoyment (z=−2.440; P=.02) and perceived competence (z=−2.170; P=.03; Table 4), whereas significant differences were not observed in levels of effort-importance (z=−1.310; P=.20) and tension-pressure (z=−0.733; P=.48).

Table . Comparison of Intrinsic Motivation Inventory (IMI) variability between the intervention and control groups.

IMI subscale	Intervention group[a] (n=18), mean (SD)	Control group[b] (n=18), mean (SD)	z score	P value[c]
Interest-enjoyment	20.28 (2.72)	18.00 (2.57)	−2.440	.02
Perceived competence	18.83 (3.05)	16.33 (3.34)	−2.170	.03
Effort-importance	12.89 (1.97)	11.83 (2.57)	−1.310	.20
Tension-pressure	10.44 (2.33)	9.77 (2.90)	−0.733	.48

Discussion

Principal Findings

The integration of science education into the foundational education of children aims to systematically cultivate their abilities in inductive and deductive thinking [34]. Serious games have demonstrated efficacy in enhancing teaching and learning outcomes within the contemporary domain of children's science education [7]. AR technology has garnered growing interest in the realm of serious game design in recent times due to its ability to visually represent scientific processes that are not easily observable in real-life situations [35]. Further, the incorporation of AR technology into mobile devices has resulted in widespread adoption, facilitating the implementation of many apps [17]. Nevertheless, there is a lack of comprehensive study and experimentation to substantiate the efficacy of AR design in the realm of children's science education. Consequently, a series of AR science instructional games were developed, focusing on the comprehension of light principles. The objective was to assess the efficacy of the games and the degree of intrinsic motivation of the students. The results showed that children who participated in the AR science game had substantially higher POE test scores and conceptual understanding of light propagation than the control group.

The study revealed that children exhibited varying levels of comprehension in relation to light concepts across diverse themes. Reliable between-group differences were detected among the topics of light propagation. The rationale behind the use of AR lies in its inherent benefits, which include the ability for children to engage in physical activity while delving into a more comprehensive exploration as compared to 2D games. Additionally, AR technology facilitates the rendering of real-world light phenomena, as supported by previous studies [36,37]. Our game was developed with the purpose of creating a metaphorical representation of concepts connected to light orientation using gesture-touch interactions. It aims to alleviate the cognitive burden experienced by children when trying to connect abstract information about light with real-world light occurrences. This is achieved by incorporating 3D properties of lighting effects into the game. Furthermore, a notable increase in the game scores of the intervention group was noticed across all topics. This observation serves as evidence for the beneficial influence of AR games on children's conceptual transformation during the process of acquiring scientific knowledge. Our game also serves as a means of scientific investigation, necessitating active engagement from the children. Certain children had not before contemplated the underlying mechanisms responsible for commonplace visual occurrences. The stimulation of their drive to study and their high curiosity played a significant role in facilitating their conceptual shift and fostering the development of scientific thinking [38]. Nevertheless, the intervention group did not exhibit any noteworthy disparity compared to the control group in relation to the topics of animal vision and color-light mixing. The limited influence of the different interactive designs, specifically mixed camera mode and projected lighting mode, on children's cognition may account for this disparity when compared to the visual representation format in the 2D game.

Intrinsic motivation is a potent factor that influences performance, learning persistence, and productivity [39]. Children in the intervention group demonstrated greater interest and enjoyment in intrinsic motivation than those in the control group, and they demonstrated an ability to embrace and comprehend the causes of certain light phenomena.

AR imparts scientific information that challenges children's prior knowledge and stimulates their interest. Consequently, it can arouse interest in the principles and stimulate active thought [35]. During the test, we observed that participants had a keen interest in the game and avidly explored the interface's interactive elements. Moreover, there was a significant difference in perceptual ability between the intervention and control groups. We believe that this difference stems from the fact that AR games, created by adding 3D virtual objects to real-world images, can better facilitate children's understanding of complex concepts [15]. However, we also found that the intervention group showed some stress toward AR games. Children have a period of adjustment for things to which they are not accustomed to, as evidenced by their inattention and attempts to communicate with the observer when they encounter difficulties in the game [17]. Future research can therefore concentrate on how to provide prompts even when encountering difficulties.

The researchers observed that the children's engagement in gameplay facilitated their conscious observation of light occurrences in their daily lives, resulting in a modest improvement in their comprehension during the final phase of the tests. Furthermore, when the optical principles pertaining to linear propagation, reflection, and refraction became increasingly complex, it became more challenging for the children to comprehend, leading to confusion in certain preintervention participants regarding the distinctions between these concepts. It is important to acknowledge that when a child misinterprets the dynamic effects, animation, or creative expression of a game feature, the game can potentially facilitate the development of novel alternative understanding. Fortunately, the occurrence of this scenario was limited in the 2 assessment tests conducted during the formal experiment.

The strengths and weaknesses of our study in comparison with other studies is shown in Table S4 in Multimedia Appendix 2.

In summary, the integration of AR into educational games has the potential to enhance children's science education by offering a more immersive and engaging learning experience. This approach also may address the challenges associated with inadequate education and the lack of motivation among children to explore scientific subjects.

Conclusions and Limitations

The results suggest that the use of AR serious games can effectively motivate children to undergo conceptual shifts during the initial phases of science education. This, in turn, leads to an improved level of comprehension of scientific material. Furthermore, it is expected that these positive outcomes can be replicated in future preschool science education settings. This randomized controlled trial provides confirmation that the science education game we developed, using AR technology, has the potential to rectify children's misconceptions regarding scientific concepts and improve the overall efficacy of science teaching.

However, there are also some limitations. First, the sample size used in the study was limited, and the sample population was mainly from the more resource-rich region of Jiangsu Province, China. Consequently, it is challenging to ascertain the presence of regional variations in other geographical areas. Prospective studies with large samples are needed to further confirm the results, and the results can be improved by considering gender, family upbringing, and children's interest preferences in subsequent studies. Second, AR apps require a lot of attention and can be a distraction. It can cause students to ignore instructions or important stages of the experience. In addition, as the situation appeared in the pre-experiment, the game as a teaching tool may generate new misconceptions if the child misinterprets the content of the game. Finally, the existing game conveys scientific concepts mostly through voice-over prompts, which are insufficient to grab the children's attention, and children may be distracted and lose essential information during the voice-over prompts.

Editorial Notice

This randomized study was only retrospectively registered, as the authors had not considered it necessary to register prospectively. The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials, because the risk of bias appears to be low. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: Retention of adult basic life support (BLS) knowledge and skills after professional training declines over time. To combat this, the European Resuscitation Council and the American Heart Association recommend shorter, more frequent BLS sessions. Emphasizing technology-enhanced learning, such as mobile learning, aims to increase out-of-hospital cardiac arrest (OHCA) survival and is becoming more integral in nursing education.

Objective: The aim of this study was to investigate whether playing a serious smartphone game called MOBICPR at home can improve and retain nursing students' theoretical knowledge of and practical skills in adult BLS.

Methods: This study used a randomized wait list–controlled design. Nursing students were randomly assigned in a 1:1 ratio to either a MOBICPR intervention group (MOBICPR-IG) or a wait-list control group (WL-CG), where the latter received the MOBICPR game 2 weeks after the MOBICPR-IG. The aim of the MOBICPR game is to engage participants in using smartphone gestures (eg, tapping) and actions (eg, talking) to perform evidence-based adult BLS on a virtual patient with OHCA. The participants' theoretical knowledge of adult BLS was assessed using a questionnaire, while their practical skills were evaluated on cardiopulmonary resuscitation quality parameters using a manikin and a checklist.

Results: In total, 43 nursing students participated in the study, 22 (51%) in MOBICPR-IG and 21 (49%) in WL-CG. There were differences between the MOBICPR-IG and the WL-CG in theoretical knowledge (*P*=.04) but not in practical skills (*P*=.45) after MOBICPR game playing at home. No difference was noted in the retention of participants' theoretical knowledge and practical skills of adult BLS after a 2-week break from playing the MOBICPR game (*P*=.13). Key observations included challenges in response checks with a face-down manikin and a general neglect of safety protocols when using an automated external defibrillator.

Conclusions: Playing the MOBICPR game at home has the greatest impact on improving the theoretical knowledge of adult BLS in nursing students but not their practical skills. Our findings underscore the importance of integrating diverse scenarios into adult BLS training.

Introduction

Sudden cardiac arrest is one of the leading causes of death in adults worldwide. It is responsible for over a million deaths annually [1]. Most deaths occur in the out-of-hospital setting, and the outcome possibly can be improved with proper adult basic life support (BLS) [2]. Effective implementation of adult BLS can double the chances of survival after a sudden cardiac arrest [3,4]. Reviews report poor cardiopulmonary resuscitation (CPR) by nursing students, despite the completion of adult BLS certification [5]. BLS knowledge and skills decline significantly within months of initial training [5,6]. For this reason, the European Resuscitation Council (ERC) and American Heart Association guidelines recommend shorter and more frequent adult BLS training as it helps retain adult BLS content longer and maintain competency levels [7,8]. Currently, adult BLS education in higher nursing education institutions traditionally imparts theoretical knowledge through a frontal approach and teaches practical skills using manikins and automated external defibrillators (AEDs), although the approach can vary significantly from one university to another [5,9].

A noticeable generational shift is evident in health care systems, both in Europe and abroad, characterized by the increasingly common employment of younger individuals. These younger future health care employees bring a higher proficiency in technology and information literacy [10,11], attributes cultivated from growing up in an era dominated by modern technology [12]. Technology-enhanced learning (TEL) approaches, developed to improve adult BLS knowledge and skill retention, ultimately aim to increase out-of-hospital cardiac arrest (OHCA) survival [8]. The most recent adult BLS guidelines highlight the integration of TEL into adult BLS courses [8,13,14]. This includes not only immersive technologies, such as extended reality [15], but also mobile learning (m-learning), which has increased dramatically in nursing education in recent years [16]. A recent meta-analysis indicates that serious smartphone games are a promising and effective tool for adult BLS education [17].

M-learning, by its definition, encompasses the use of mobile technology [18], with mobile apps on smartphones often serving as the educational platform [19]. Research has demonstrated m-learning's beneficial effects on fostering a variety of learning outcomes and competencies in the field of nursing [20,21]. Smartphone-based m-learning [21] seamlessly complements education through serious games and gamification [15]. Gamification involves applying game design elements to nongame contexts [22], such as educational content in higher education [23]. Conversely, serious games are crafted to use a specific type of game (eg, computer or mobile games) for the purpose of learning about significant subjects, such as adult BLS content education at the higher education level [24].

To the best of our knowledge, only a limited number of studies have explored the use of serious smartphone games for teaching adult BLS to health care students [25-29]. Among these, only 1 study demonstrated an improvement in both the theoretical knowledge and practical skills associated with adult BLS [28]. Other studies have reported enhancements in either theoretical knowledge [29] or practical skills related to adult BLS. The positive effects of a serious smartphone game can be seen as early as 2 weeks [25,26], as well as 1 month after the intervention [27-29]. Studies have compared different teaching methods, where the use of serious smartphone games seems to have better results than simulation-based learning but is less effective than virtual reality–based game learning [26,30]. Some studies have also shown improvements in practical skills, such as compression rate accuracy [27,28], although this tends to be inferior when compared to simulation-based methods [30]. In contrast, in 2 studies, serious smartphone games did not provide notable benefits and led to worse performance in theoretical and practical areas, although students showed a clear preference in favor of serious smartphone games [27,28].

The aim of the study was to evaluate whether playing a serious smartphone game called MOBICPR [31] at home can enhance nursing students' theoretical knowledge of and practical skills in adult BLS.

Methods

Study Protocol

The study was conducted at the Faculty of Health Sciences, University of Maribor (Maribor, Slovenia) between March and May 2023. The study was registered in ClinicalTrials.gov (NCT05784675). The study protocol was written in accordance with the Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth (Multimedia Appendix 1) [32].

Ethical Considerations

Ethical approval was obtained from the Slovenian National Medical Ethics Committee (0120-157/2018), and permission to conduct the study on the faculty premises was obtained from the Faculty of Health Sciences, University of Maribor. During an oral presentation of the study, nursing students were informed about the research protocol, and written consent was obtained afterward. Data confidentiality and anonymity were maintained throughout the study. Participants were rewarded for their participation in the study with a free beverage from a vending machine and a copy of the *Game Changer* painting by street artist Banksy [33].

Participants

All nursing students enrolled in the first-degree nursing program at the Faculty of Health Sciences, University of Maribor, during the 2022-2023 academic year were invited to participate in the study. Inclusion criteria to participate in the study were written informed consent, an age of at least 18 years, and ability to perform adult BLS on a manikin (eg, without injury). Our study had no exclusion criteria.

Study Design and Randomization

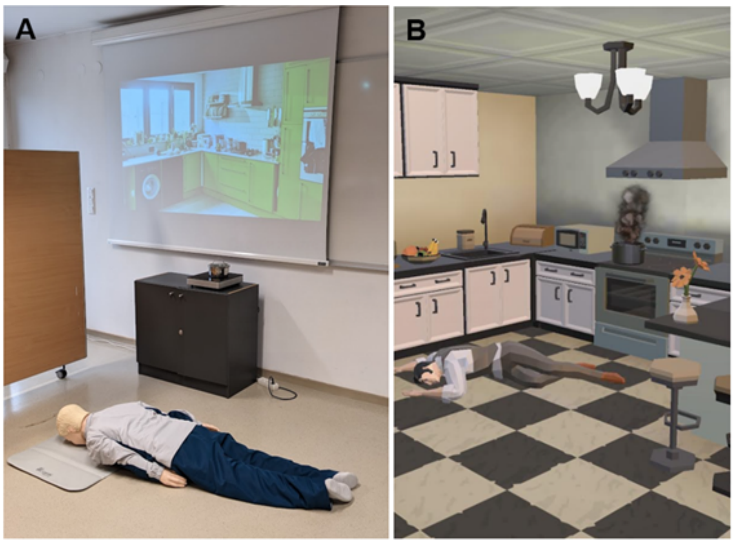
This study had a randomized wait list–controlled design, where nursing students were randomly assigned in a 1:1 ratio using a computer-generated list (Microsoft 365 Excel Enterprise) to either a MOBICPR intervention group (MOBICPR-IG) or a wait-list control group (WL-CG). The WL-CG was a group of nursing students who were assigned to a wait list and received the intervention (MOBICPR game for playing at home) 2 weeks after the MOBICPR-IG.

Interventions

All assessments of the participants' theoretical knowledge of and practical skills in adult BLS were conducted 3 time points: baseline, 2-week follow-up, and 4-week follow-up. At the baseline assessment, the investigators first collected demographic data from the participants. Additionally, the participants were questioned about their willingness to assist both family members and strangers during OHCA with CPR. Prior to practical skills in adult BLS, participants' the theoretical knowledge of adult BLS was assessed using a questionnaire with 33 single- and multiple-choice questions [25,34-36] on an open source online survey app called 1ka (Ljubljana, Slovenia); see Multimedia Appendix 2. A back-translation approach was used for translating the questionnaire into the Slovenian language.

Prior to the assessment of adult BLS practical skills, each participant was given a scenario based on OHCA to read (Multimedia Appendix 3). After reading the scenario, the participants were given a smartphone for calling emergency services at the time of performing adult BLS. Instead of dialing the actual emergency number, the participants used the contact stored on the smartphone as 112 (ie, the Slovenian emergency number). After the call was placed by each participant, the investigator answered the phone and conducted a simulated dispatcher conversation [37]. The investigator was a registered nurse working at the local medical dispatch center. Each participant performed 2-minute adult BLS without any help in a staged kitchen on a manikin (Resusci Anne Quality Cardiopulmonary Resuscitation [QCPR], Laerdal Medical) using an AED (Defibtech, Trainer AED). The staged kitchen was a space surrounded by mobile walls in the hospital's simulated room. A photo of a kitchen was projected onto the wall, and below it was an electric stove with a pot full of water (Figure 1). In each adult BLS scenario, the investigators turned on the electric stove, and the scenario began when the water started to boil, simulating a hazard. The kitchen was chosen because the majority of OHCAs occur there [38].

Figure 1. Staged kitchen with the Resusci Anne QCPR in the middle (A) and a cartoon person in the MOBICPR game lying on the floor in a kitchen (B). QCPR: Quality Cardiopulmonary Resuscitation.



After 2 minutes of performing adult BLS, each participant received assistance from an outside person bringing in an AED and taking over CPR. The adult BLS practical skills of each participant were recorded using a Sony Handycam 4K AX53 camera and an Apple iPad Pro 3rd generation tablet. Two investigators with a background in emergency medicine and teaching laypersons adult BLS assessed the participants' practical skills in adult BLS using a modified checklist [25,36,39] according to the ERC BLS guidelines of 2015 [40] and 2021 [34], with a total of 34 items (Multimedia Appendix 4). A back-translation approach was used for translating the checklist into the Slovenian language. Numerical data from the

SkillReporter for Tablet version 1.4.1 (Laerdal Medical) app installed on a Samsung Galaxy Tab S6 Lite tablet was also included in the evaluation of the participants' practical skills in adult BLS. Investigator debriefing was not conducted following the assessment of the participants' adult BLS theoretical knowledge and practical skills. Instead, each participant (from MOBICPR-IG at baseline and from WL-CG 2 weeks after baseline) first played the MOBICPR game [31] on a Samsung Galaxy A13 smartphone in front of the investigator and then received the same smartphone to play at home. The objective of the MOBICPR game is for participants to interact with a smartphone using gestures (eg, tapping) and actions (eg, talking) to help save the life of a virtual patient with OHCA by performing evidence-based adult BLS. The MOBICPR game is based on the 2021 ERC BLS guidelines [34], and the BLS content was developed using the Delphi process. The patient's chance of survival in the MOBICPR game reduced with each incorrect interaction by the participants. At the end of the MOBICPR game, each participant received a total score in the form of a gamification feature that corresponded to the risk of survival (score>50% meant the patient survived) [41]. Gamification, defined as "using game design elements in non-game contexts," has been introduced into nursing education to promote engagement using features such as leaderboards, rewards, badges, and avatars [22]. After playing the MOBICPR game as much as they wanted for 2 weeks, participants in the MOBICPR-IG returned the smartphones. Participants in the W-CG then received the smartphones and followed the same protocol as participants in the MOBICPR-IG, that is, they played the MOBICPR game in front of the investigator before taking the smartphone home. Participants in the W-CG also returned the smartphones after playing the MOBICPR game at home for 2 weeks. Additionally, at the study's conclusion, each participant was asked an open-ended question regarding the number of family members or friends with whom they shared the MOBICPR game for playing.

Outcome Measures

The primary outcomes were (1) assessment of the participants' theoretical knowledge of adult BLS using a questionnaire with a total maximum score of 33 points, where each correct answer was awarded 1 point (Multimedia Appendix 2), and (2) assessment of the participants' practical skills in adult BLS using a checklist with a total maximum score of 39 points (Multimedia Appendix 4).

The secondary outcome was a summary score of high-quality CPR components: (1) a chest compression (CC) rate of 100-120 beats per minute (bpm), (2) a CC depth of 50-60 mm, (3) CC fraction>80%, and (4) a rescue breath volume of 500-600 mL (Multimedia Appendix 4). All measures were taken as mentioned earlier [16,23,27,28]. A total QCPR score was also included, ranging from 0% to 100%. More detailed information about software scoring is available on the Laerdal Medical website [42]. Both primary and secondary outcomes were measured at 3 time points: baseline, 2-week follow-up, and 4-week follow-up.

Statistical Analysis

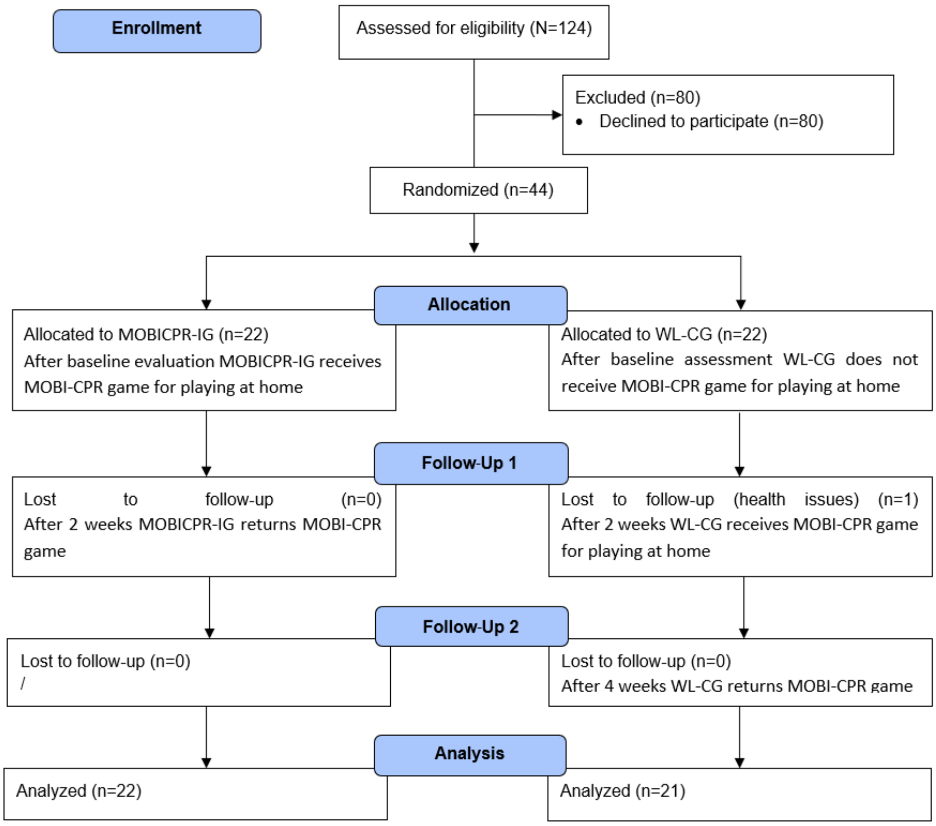
Statistical analyses were conducted in October and November 2023. Data were analyzed using the R statistical programming language (R Foundation for Statistical Computing). The data presented in the summary table were prepared using frequency analysis, which also included a chi-square test to assess the similarity of the distribution between the intervention and control groups. Theoretical knowledge and practical skill assessments were averaged at the item level and subsequently analyzed using nonparametric statistical tests (Wilcoxon paired-sample test and Mann-Whitney *U* test) as the normality of the distribution was violated. As nonnormal distribution might represent a problem when calculating mean values, violin plots were also used for the purpose of visualizing aggregated scores due to their ability to visualize the distribution of the data. $P<.05$ was considered statistically significant. Effect size (η^2) values >0.1 represented a small effect; 0.3, a moderate effect; and ≥0.5, a large effect. Continuous variables were analyzed according to the Gaussian distribution and reported as the mean (SD) or the median (IQR), whichever was appropriate.

Results

Participant Details

Of 124 nursing students, 80 (64.5%) declined to participate in the study and 44 (35.5%) were enrolled into the study. At follow-up, 1 (5%) of the 22 participants in the WL-CG dropped out. In the end, 43 (98%) of 44 participants were included in the final analysis (Figure 2).

Figure 2. Flow diagram of study participants. MOBICPR-IG: MOBICPR intervention group; WL-CG: wait-list control group.



The mean age of the participants was 19 (SD 0.6) years, 38 (88%) were female, 35 (81%) had a background in health care and nursing education, 32 (74%) had an iOS smartphone, and the self-reported mean daily time spent on the smartphone was 3.8 (SD 1.2) hours (Table 1).

[d]Not applicable.

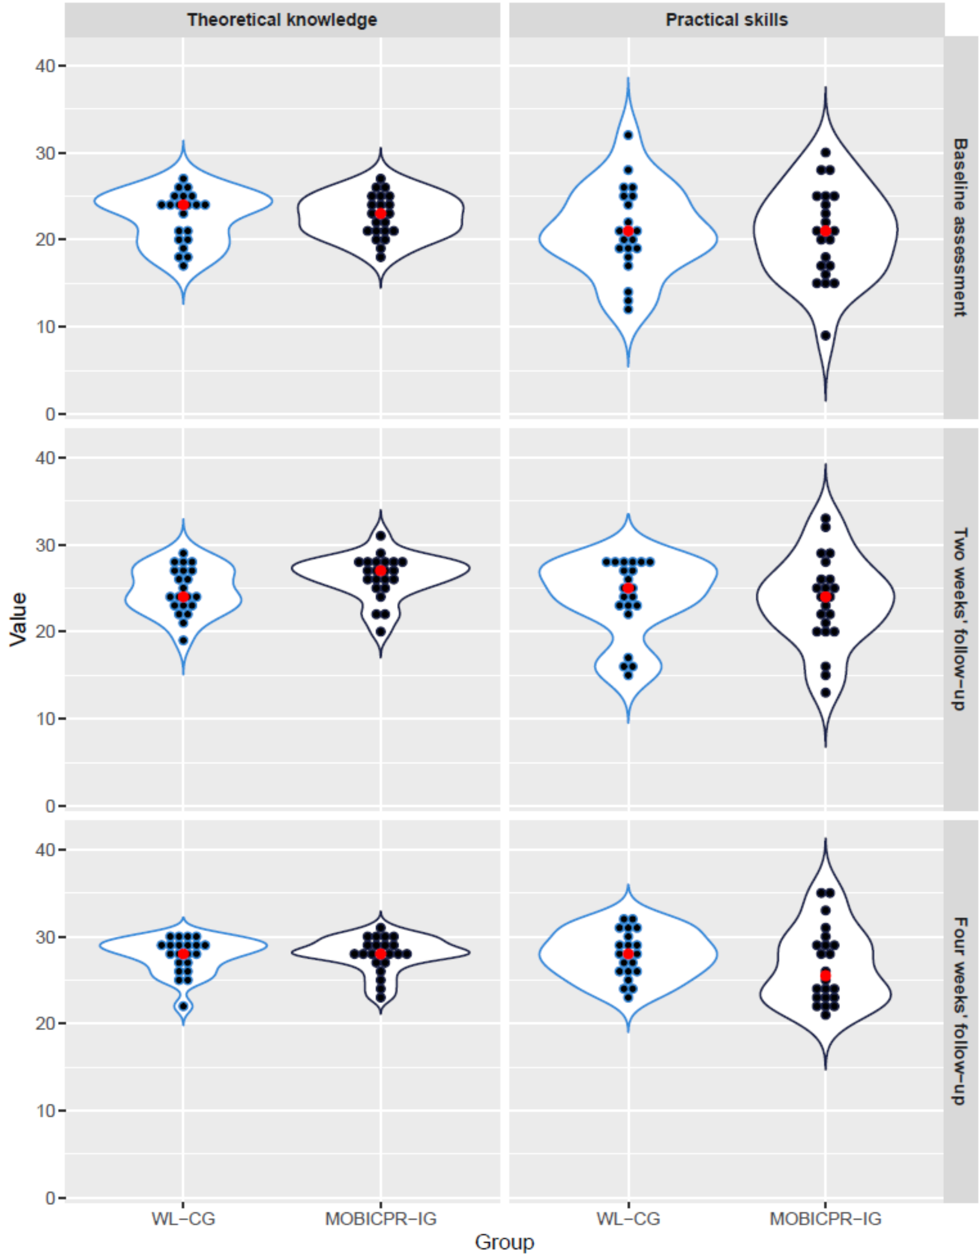
All participants had received some previous adult BLS training. However, only 2 (5%) had witnessed a cardiac arrest. Most of them (n=38, 88%) had already performed CCs on manikins, but only a few had also been giving rescue breaths (n=12, 28%) and used any kind of AED (n=13, 30%). All participants (n=43, 100%) expressed a willingness to assist a patient with OCHA and perform adult BLS. In addition, they all expressed a willingness to perform mouth-to-mouth resuscitation on a family member or acquaintance. However, only about half of them (n=19, 44%) were willing to do the same for a stranger. The predominant concern for not administering rescue breaths to unknown individuals was the uncertainty regarding the patient's medical history and the risk for infectious diseases, as cited by 22 (92%) of the 24 (56%) participants who expressed reluctance. On average, each participant introduced and shared the MOBICPR game with 3 (SD 2) family members or friends for trial and play.

Primary Outcomes

To assess the differences between the 2 groups at all 3 observed time points, we calculated the cumulative scores of adult BLS theoretical knowledge and practical skills for both groups.

Figure 3 shows that playing the MOBICPR game at home for 2 weeks improved the overall adult BLS theoretical knowledge (median gain of 4 points, IQR 3, η^2=0.113, *P*=.005) and practical skills (median gain of 4 points, IQR 7, η^2=0.05, *P*=.04). However, in the WL-CG, which waited for 2 weeks to play the MOBICPR game at home, the theoretical knowledge of adult BLS improved by 2 points (IQR 4, η^2=0.302, *P*=.001), whereas the practical skills in adult BLS increased by 3 points (IQR 3, η^2=0.018, *P*=.14). In the MOBICPR-IG, after 2 weeks of not playing the MOBICPR game at home, the retention of theoretical knowledge gained an additional 2 points (IQR 2, η^2=0.019, *P*=.13) and practical skills gained 3 points (IQR 3.75, η^2=0.122, *P*=.003) compared to the 2-week follow-up.

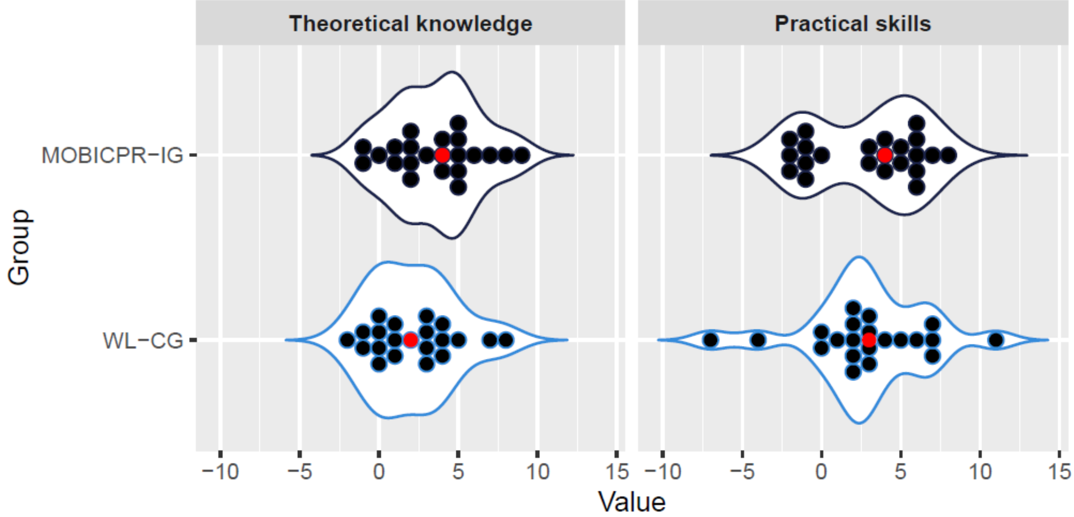
Figure 3. Comparison of theoretical knowledge and practical skill scores for all study participants at baseline, 2-week follow-up, and 4-week follow-up measurements. MOBICPR-IG: MOBICPR intervention group; WL-CG: wait-list control group.



To focus on the impact of playing the MOBICPR game on adult BLS theoretical knowledge and practical skills, we observed participants in both groups and calculated the difference in the cumulative points for both groups after they played the MOBICPR game at home for 2 weeks.

As demonstrated in Figure 4, in the WL-CG, only 3 (14%) participants improved their theoretical knowledge by ≥5 points and only 6 (29%) study participants who achieved this kind of improvement in the adult BLS practical skill score. In contrast, in the MOBICPR-IG, 9 (41%) participants improved their score by at least 5 points in both adult BLS theoretical knowledge and practical skills. The difference in improvement between the MOBICPR-IG and the WL-CG was not significant in practical skills (η^2=0.021, *P*=.45), while in theoretical knowledge, we observed a statistically significant difference (η^2=0.268, *P*=.04).

Figure 4. Difference in theoretical knowledge and practical skills score before and after playing the MOBICPR game. MOBICPR-IG: MOBICPR intervention group; WL-CG: wait-list control group.



To obtain more detailed insight into the improvements due to playing the MOBICPR game, we observed the differences in item-level scores before and after playing. Table 2 compares the participants' scores on questions used to test their theoretical knowledge. It is evident that there were notable differences in most items following engagement with the MOBICPR game. Of 33 scores, 13 (39%) decreased during MOBICPR game playing. For example, the score on question 3 (What is the second thing we check in a patient with cardiac arrest?) improved notably after MOBICPR game playing at home (*P*=.001). In contrast, the score on question 16 (You are alone. Will you go for the AED if it is 100 m away?) did not improve after MOBICPR game playing at home (*P*=.103).

Table 2. Question-level comparison of the mean scores for adult BLS[a] theoretical knowledge evaluation for MOBICPR-IG[b] and WL-CG[c] before and after MOBICPR game playing at home for 2 weeks (N=43).

Questions for evaluation of adult BLS theoretical knowledge	Score before playing the MOBICPR game at home, mean (SD)	Score after playing the MOBICPR game at home, mean (SD)	Difference (after – before)	*P* value
1. What is the first thing we check when we approach the patient?	2.51 (0.86)	1.72 (0.43)	–0.79	.04
2. On what kind of surface do we perform adult BLS?	2.88 (0.45)	2.09 (0.34)	–0.79	.001
3. What is the second thing we check in a patient with cardiac arrest?	2.14 (0.74)	2.93 (0.58)	0.79	.001
4. How many seconds do we need to assess consciousness?	1.74 (0.54)	1.95 (0.43)	0.21	.05
5. Before we assess breathing or perform CC[d], do we remove the patient's clothes?	1.26 (0.44)	1.77 (0.21)	0.51	.001
6. How do we open the airway?	2.95 (0.21)	1.05 (0.15)	–1.91	.001
7. What maneuver do we use to open the airway?	1.02 (0.15)	2.98 (0)	1.95	.001
8. How do we assess breathing?	2.95 (0.3)	1.00 (0)	–1.95	.001
9. How many seconds do we need to assess breathing?	1.51 (0.86)	3.00 (0)	1.49	.001
10. What is the most common breathing in a patient with cardiac arrest?	2.47 (0.83)	1.00 (0.63)	–1.47	.001
11. Who are you calling on the 112 number?	3.16 (0.37)	2.12 (0.32)	–1.05	.001
12. Will calling 911 in Slovenia or Europe reach emergency services?	1.72 (0.45)	3.12 (0.5)	1.40	.001
13. Who dials 112 in the case of cardiac arrest?	2.81 (0.55)	1.58 (0.3)	–1.23	.001
14. What do we need to tell the emergency medical dispatcher?	2.51 (0.51)	2.95 (0.51)	0.44	.001
15. What do you do with the phone after providing all the data?	1.91 (0.29)	2.70 (0.15)	0.79	.001
16. You are alone. Will you go for the AED[e] if it is 100 m away?	1.88 (0.32)	1.98 (0.35)	0.09	.10
17. You have help. Will you send it for the AED if it is 2 minutes away?	1.02 (0.15)	1.86 (0.15)	0.84	.001
18. Is this the sign for an AED?	2.00 (0)	1.02 (0)	–0.98	.001
19. Which picture shows the correct hand grip for CPR[f]?	2.00 (0)	2.00 (0.15)	0	.99
20. What is the right depth for CCs?	2.44 (0.77)	2.02 (0.35)	–0.42	.001
21. What is the correct body position for CCs?	1.98 (0.15)	2.86 (0)	0.88	.001
22. Where is the right place for CCs?	1.19 (0.59)	2.00 (0.78)	0.81	.001
23. What is the right frequency for CCs?	2.65 (1.41)	1.23 (0.48)	–1.42	.001
24. What is the CC-to-breath ratio for an adult?	1.98 (0.15)	1.09 (0.46)	–0.88	.001
25. How long can you interrupt CCs for rescue breaths?	1.30 (0.6)	1.93 (0.51)	0.63	.001
26. What is the volume of a rescue breath?	1.88 (0.59)	1.30 (0.26)	–0.58	.02
27. What do you do first if you have an AED?	2.58 (0.91)	2.93 (0.82)	0.35	.002
28. What do we do during AED rhythm analysis?	2.19 (0.59)	2.42 (0.46)	0.23	.17
29. What do we do during AED defibrillation?	1.00 (0)	2.07 (0)	1.07	.001

Questions for evaluation of adult BLS theoretical knowledge	Score before playing the MOBICPR game at home, mean (SD)	Score after playing the MOBICPR game at home, mean (SD)	Difference (after – before)	*P* value
30. Which of the following statements about the use of AEDs is false?	3.02 (1.3)	1.00 (1.05)	–2.02	.001
31. What do we do after the AED delivers an electric shock?	2.63 (0.69)	3.47 (0.65)	0.84	.001
32. When do we stop CPR?	1.74 (0.44)	2.91 (0.39)	1.16	.001
33. When is it recommended to replace someone during CPR?	1.72 (2.20)	1.81 (0.52)	0.09	.80
Cumulative score	2.08 (0.44)	2.06 (0.26)	0.03	.89

Similarly, in the item-level score differences for practical skills, in 7 (21%) of 34 items, a significant increase was calculated (Table 3). For example, the score on item 1 (Approaches the patient safely) improved after MOBICPR game playing at home (*P*=.001). In contrast, the score on item 2 (Checks responsiveness: shouts and shakes the patient) did not improve after MOBICPR game playing at home (*P*=.81).

Table 3. Item-level comparison of the mean scores for adult BLS[a] practical skill evaluation for MOBICPR-IG[b] and WL-CG[c] before and after MOBICPR game playing at home for 2 weeks (N=43).

Items for evaluation of adult BLS practical skills	Score before playing the MOBICPR game at home, mean (SD)	Score after playing the MOBICPR game at home, mean (SD)	Difference (after – before)	*P* value
1. Approaches the patient safely	0.09 (0.29)	0.95 (0.46)	0.86	.001
2. Checks responsiveness: shouts and shakes the patient	0.67 (0.47)	0.70 (0.32)	0.02	.81
3. Opens the airway: head tilt–chin lift	0.40 (0.49)	0.88 (0.46)	0.49	.001
4. Performs look, listen, feel	0.74 (0.44)	0.70 (0.15)	–0.05	.62
5. Looks, listens, feels: time	0.53 (0.74)	0.98 (0.78)	0.44	.001
6. Calls 112 in the first minute	0.65 (0.48)	1.35 (0.26)	0.70	.001
7. Calls 112 at the right time	0.65 (0.48)	0.93 (0.29)	0.28	.003
8. Turns on the phone speaker and immediately starts CPR[d]	0.33 (0.47)	0.91 (0.49)	0.58	.001
9. Provides correct information to the dispatcher	0.33 (0.47)	0.37 (0.5)	0.05	.62
10. Provides information about the location	0.21 (0.41)	0.42 (0.5)	0.21	.05
11. Time to the first CCs[e]	0.51 (0.51)	0.56 (0.5)	0.05	.68
12. Corrects the body position for CCs	0.72 (0.45)	0.53 (0.32)	–0.19	.07
13. Corrects the CC location	0.88 (0.32)	0.88 (0.35)	0.00	.99
14. Corrects hand CCs	0.72 (0.45)	0.86 (0.41)	0.14	.11
15. Corrects the CC depth	1.49 (0.8)	0.79 (0.9)	–0.70	.001
16. Recoil of the chest	0.79 (0.41)	1.26 (0.21)	0.47	.002
17. Corrects the CC rate	1.42 (0.7)	0.95 (0.76)	–0.47	.001
18. Ratios CCs	0.91 (0.68)	1.37 (0.53)	0.47	.004
19. CC fraction	0.84 (0.43)	0.95 (0.38)	0.12	.17
20. Opens the airway: head tilt–chin lift	0.44 (0.5)	0.95 (0.45)	0.51	.001
21. Closes the nose and fits lips around the patient’s mouth	0.63 (0.49)	0.72 (0.37)	0.09	.32
22. Average pause of ventilation	0.70 (0.46)	0.84 (0.43)	0.14	.08
23. Opens the nose	0.02 (0.15)	0.77 (0.32)	0.74	.001
24. Looks for the chest to rise between 2 rescue breaths	0.37 (0.49)	0.12 (0.51)	–0.26	.003
25. Two rescue breaths	0.84 (0.37)	0.51 (0)	–0.33	.001
26. Volume of rescue breaths	0.53 (0.7)	1.00 (0.65)	0.47	.001
27. Switches on the AED[f] first at the right time	0.49 (0.51)	0.65 (0.46)	0.16	.20
28. Removes clothing	0.98 (0.15)	0.70 (0)	–0.28	.001
29. Position of the right AED pad	0.28 (0.45)	1.00 (0.45)	0.72	.001
30. Position of the left AED pad	0.47 (0.5)	0.28 (0.5)	–0.19	.103
31. Ensures nobody is touching the patient: analyzing	0.51 (0.51)	0.44 (0.5)	–0.07	.58
32. Ensures nobody is touching the patient: shock	0.09 (0.29)	0.58 (0.26)	0.49	.001
33. Presses the shock button at the right time	0.67 (0.47)	0.07 (0.44)	–0.60	.001

Secondary Outcomes

Table 4 shows a comparison of the high-quality CPR components between participants before and after MOBICPR game playing at home for 2 weeks. There were notable differences in the median (IQR) of the total QCPR score for MOBICPR game playing at home for 2 weeks for the MOBICPR-IG (before: median 41 (IQR 54); after: median 70 (IQR 41); *P*=.011). There was no difference for the MOBICPR-IG after not playing the MOBICPR game at home for 2 weeks.

Table 4. Results for high-quality CPR[a] components for the MOBICPR-IG[b] and the WL-CG[c].

High-quality CPR components	Baseline assessment[d], median (IQR)	Score after 2 weeks of playing the MOBICPR game at home[e], median (IQR)	*P* value[d,e]	Score after 2 weeks of not playing the MOBICPR game at home[c], median (IQR)	*P* value[e,f]

Discussion

Principal Findings

In this study, playing the MOBICPR game at home for 2 weeks improved the theoretical knowledge of adult BLS in the participants but little their practical skills. These outcomes were expected, considering that the MOBICPR game was designed primarily to impart theoretical knowledge of adult BLS, rather than providing hands-on practice with an actual BLS manikin. To the best of our knowledge, only 2 studies have used data collected from manikin software to evaluate the practical parts of adult BLS as we did [27,28]. We observed in our study population that both the CC rate and the CC depth remain within the margins of the current ERC recommendation [34]; in comparison to our results, in the 2 studies [27,28], both the CC rate and the CC depth dropped below the margins after serious smartphone game playing. These 2 studies [27,28] also presented the total QCPR scores, and where our scores improved compared to theirs. Consequently, we recommend considering the MOBICPR game as a supplementary educational tool in future BLS course formats that incorporate immersive technologies [43,44] for retention of adult BLS knowledge.

In evaluating study participants performing adult BLS on a manikin, we observed 5 learning points (all reported in Tables 2 and 3), which could be useful for debriefing topics after BLS courses. Initially, a large number of participants struggled with checking the manikin's response as it lay face down. Some checked the response without turning the manikin onto its back, while others did so with the manikin still face down. After playing the MOBICPR game at home, only a minority checked the response after turning the manikin onto its back. Studies show that two-thirds of all patients are found in positions unsuitable for performing CCs, such as the recovery position [45]. The second learning point concerned the right time for chest exposure during CPR. Many participants removed the clothing before looking, listening, and feeling for signs of breathing, while others did so before applying AED electrodes to the manikin's bare chest. Studies indicate that exposing the chest during CPR can improve the rescuer's ability to locate the center of the patient's chest, leading to more effective CCs and reducing the risk of inaccurate compressions [46]. The third point was about shouting for help. A recent study revealed that almost all European BLS instructors teach laypersons to shout for help [47], even though it was removed from the ERC BLS guidelines [34,40]. Despite playing the MOBICPR game at home, the participants still tended to shout for help before calling emergency services. As a fourth point, we noticed that some participants attempted to multitask by calling the dispatcher and performing CCs simultaneously. This practice resulted in lower-quality CCs, as the focus was divided between providing information to the dispatcher and maintaining the 30:2 CC-to-rescue-breath ratio. Generation Z, like the participants in our study, tends to multitask and is more engaged in independent work [48]. Considering this insight, we are re-evaluating the recent ERC BLS guidelines, particularly their recommendation to activate the speakerphone or another hands-free feature on a mobile device before promptly initiating CPR [34]. Finally, we observed that almost all study participants failed to ensure safety before defibrillation when using an AED on the manikin. Issues arose before pressing the shock button, either because they did not check whether someone was touching the manikin or because they pressed the shock button prematurely. This highlights that using an AED is not intuitive for laypersons, as studies suggest, and special training should be considered [49].

The International Liaison Committee on Resuscitation provides a scientific statement on teaching laypersons adult BLS and suggests using TEL, such as serious smartphone games, to engage, motivate, and educate children and adolescents in saving more lives [34]. Several legitimate smartphone games have been identified as suitable for teaching adult BLS, but their content is questionable because it does not follow current BLS guidelines [50,51]. Moreover, most of them teach only hands-on CPR. Some also include ventilation and AED use [51]. However, the MOBICPR game was developed based on recent ERC BLS guidelines [34] and includes all the recommended BLS steps. In a recent MOBICPR study, students agreed that it was beneficial to play the MOBICPR game before practicing adult BLS on a manikin [41]. They also highly rated the usability of the MOBICPR game for providing adult BLS theoretical knowledge and practical skills. The results show that the MOBICPR game could be a novel, interactive, evidence-based BLS educational tool for playing at home after adult BLS training [41,52]. Moreover, our study revealed that the MOBICPR game could be an effective method for enhancing bystander willingness and awareness in performing CPR. This potential is demonstrated by the fact that all study participants introduced the MOBICPR game to their family members, relatives, or friends, as seen in similar studies where enhanced technology was used teaching adult BLS [53].

This gamified learning approach fits well with the educational theory heutagogy, also known as self-determined learning, where learners determine what they want to learn [8]. In the case of the MOBICPR game, learners can play it at any time to refresh their adult BLS knowledge without waiting for the next training session [54]. Moreover, the use of do-it-yourself manikins made from everyday items, such as plastic bottles, toilet paper, or even a pillow, for practicing CC techniques at home, especially in low-resource settings, coupled with the MOBICPR game, can potentially improve and solidify practical skills in adult BLS [55-58]. The MOBICPR game also includes gamification features, such as avatars, points, and various audio, textual, and graphical feedback. These gamification elements could motivate learners to engage with the game more frequently than they normally would [59]. Future educational tools, such as the MOBICPR game, should align with the 5 key messages outlined in the recent ERC BLS guidelines, ranging from recognizing cardiac arrest to learning the proper techniques for performing CPR [34]. This adherence is crucial for the effective education and retention of adult BLS skills, particularly following adult BLS courses in a home environment.

Limitations

This study has several limitations. First, because the study participants were only followed for 4 weeks, we were not able to show that the MOBICPR game improved their long-term retention of resuscitation knowledge and skills. Second, the sample size was small due to the lack of interest of participants in participating in the study and because only 1 generation of participants was able to be included at that time. Third, this was a single-faculty study, which limits the generalizability of the results. Fourth, in this study, participants were familiar with smartphone games. It is unclear how effective the MOBICPR game would be in children or older populations. Fifth, because this was a simulation-based study, the performance results may not be generalizable to real-life situations and could not present the impact on patient outcomes. Finaly, the content in the MOBICPR game was developed by researchers based on recent ERC BLS guidelines [34]. In the future, there are plans to introduce the MOBICPR game to the Slovenian National Resuscitation Council, with the goal of securing its certification, a process akin to that followed by the Italian Resuscitation Council for its smartphone-based serious games [60].

Conclusion

The home use of the MOBICPR game shows promise in enhancing the theoretical knowledge of adult BLS. Although there was no significant improvement in performing adult BLS or in retaining the related knowledge and skills, the study yielded important learning objectives for the enhancement of future adult BLS training. Further research is necessary to explore its lasting effects across various demographics and to determine the most effective use of the MOBICPR game in teaching adult BLS.

Acknowledgments

NF and GŠ are supported by Slovenian Research Agency (grants ARRS P2-0057, ARRS N3-0307, ARRS BI-US/22-24-138), NextGenerationEU, and the Ministry of Higher Education, Science and Innovation (C3330-22-953012). The authors would like to thank all nursing students who participated in this study.

Authors' Contributions

The study was carried out through collaboration among all authors. NF developed the study design and supervised the study. NF, GŠ, and ŠM drafted the manuscript. NF, GŠ, RG, and ŠM conducted data collection and analysis. NF, MS, PS, and RG interpreted results from the cardiopulmonary resuscitation point of view. RMC and RG conducted a comprehensive content review. All authors have read, revised, and approved the final manuscript.

Conflicts of Interest

NF is a member of the European Resuscitation Council (ERC) basic life support (BLS) Science and Education Committee. RG is the ERC director of guidelines and the International Liaison Committee on Resuscitation (ILCOR) and chair of the ILCOR Education, Implementation, and Teams Task Force. Other authors declare no conflicts of interest.

Abstract

Background: In the wake of challenges brought by the COVID-19 pandemic to conventional medical education, the demand for innovative teaching methods has surged. Nurse training, with its focus on hands-on practice and self-directed learning, encountered significant hurdles with conventional approaches. Augmented reality (AR) offers a potential solution to addressing this issue.

Objective: The aim of this study was to develop, introduce, and evaluate an AR-based educational program designed for nurses, focusing on its potential to facilitate hands-on practice and self-directed learning.

Methods: An AR-based educational program for nursing was developed anchored by the Kern six-step framework. First, we identified challenges in conventional teaching methods through interviews and literature reviews. Interviews highlighted the need for hands-on practice and on-site self-directed learning with feedback from a remote site. The training goals of the platform were established by expert trainers and researchers, focusing on the utilization of a ventilator and extracorporeal membrane oxygenation system. Intensive care nurses were enrolled to evaluate AR education. We then assessed usability and acceptability of the AR training using the System Usability Scale and Technology Acceptance Model with intensive care nurses who agreed to test the new platform. Additionally, selected participants provided deeper insights through semistructured interviews.

Results: This study highlights feasibility and key considerations for implementing an AR-based educational program for intensive care unit nurses, focusing on training objectives of the platform. Implemented over 2 months using Microsoft Dynamics 365 Guides and HoloLens 2, 28 participants were trained. Feedback gathered through interviews with the trainers and trainees indicated a positive reception. In particular, the trainees mentioned finding AR particularly useful for hands-on learning, appreciating its realism and the ability for repetitive practice. However, some challenges such as difficulty in adapting to the new technology were expressed. Overall, AR exhibits potential as a supplementary tool in nurse education.

Conclusions: To our knowledge, this is the first study to substitute conventional methods with AR in this specific area of critical care nursing. These results indicate the multiple principal factors to take into consideration when adopting AR education in hospitals. AR is effective in promoting self-directed learning and hands-on practice, with participants displaying active engagement and enhanced skill acquisition.

Trial Registration: ClinicalTrials.gov NCT05629663; https://clinicaltrials.gov/study/NCT05629663.

Introduction

In recent years, conventional education, especially in the medical field, has been challenged by the introduction of new technologies [1]. The COVID-19 pandemic further highlighted the limitations of conventional teaching methods [2]. Nurse training, with its emphasis on hands-on practice and self-directed learning, was particularly affected by the pandemic, making it evident that conventional training methods could not sustain the demands of the situation [3,4]. Given these constraints, the search for alternative, technology-driven educational methods intensified, aiming to address both physical resource and time challenges without compromising education quality [5,6]. In this context, an immersive learning environment, based on a computer-generated environment enabling real-time user interactions [7], has emerged as a promising solution.

Such an immersive platform merges augmented reality (AR) and virtual reality (VR), offering a dynamic 3D space for learners. This integration not only enhances the learning experience by providing a rich, immersive environment [8,9] but also reshapes the boundaries between reality and the virtual realm, paving the way for innovative learning avenues [10,11]. Exploring AR's potential reveals that its uses surpass merely aiding in remote education. AR also introduces real-time feedback mechanisms, empowering trainees to obtain immediate insights about their actions and performance through virtual aids [12,13]. This immediacy in feedback is invaluable, as it allows errors to be addressed promptly, fostering continuous improvement in learning [14,15].

In the field of critical care, there has been an exploration of the use of AR and VR in educational applications [16]. VR-enhanced training for tracheostomy care in the intensive care unit (ICU) setting has demonstrated the potential of education in an immersive learning environment [17,18]. Studies have been conducted for training mechanical ventilator settings and central line insertion, showing improvements in self-efficacy, increased familiarity, confidence, and reduced anxiety compared to conventional methods [13,17,19]. However, while the advantages are evident, existing research into AR and VR remains limited. These studies are usually one-time or short-term investigations, mainly focusing on the effectiveness of the immersive learning environment [20]. Moreover, integrating these technologies into a nursing curriculum represents an area yet to be fully explored [21].

In this study, we aimed to derive key considerations for each phase of implementation based on our experience of introducing an AR nursing program within an ICU in a tertiary hospital setting.

Methods

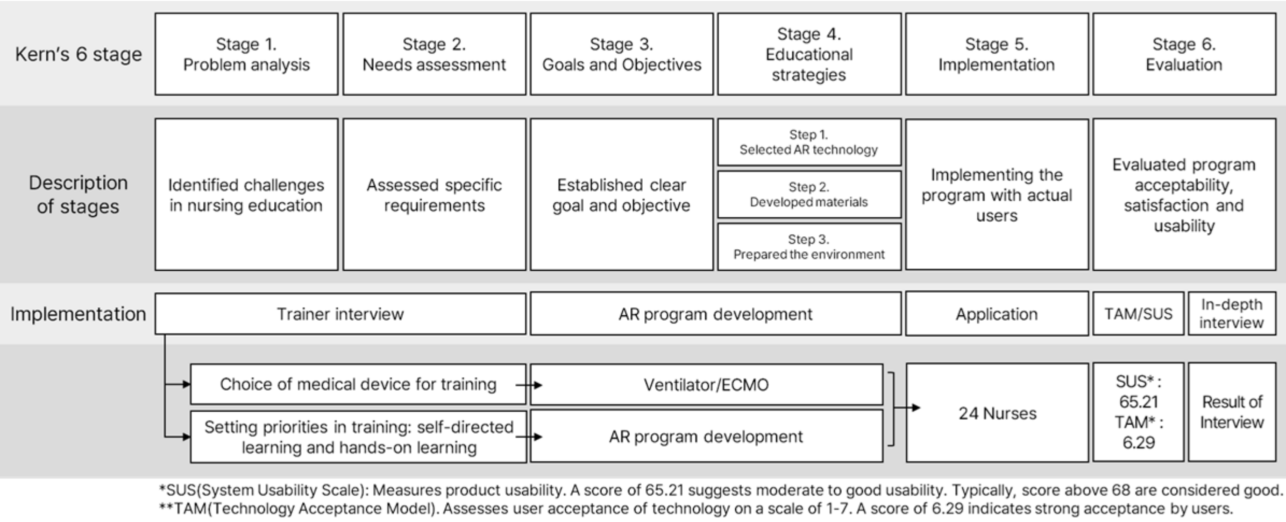
Experimental Design

Overview

Our methodology was refined based on the Kern six-step approach to transition nursing education into an immersive AR-based format [22], focusing on the following key stages: (1) problem identification, (2) needs assessment, (3) setting goals and objectives, (4) choosing educational strategies, (5) implementation, and (6) evaluation [23] (Figure 1).

Our initial steps involved conducting interviews with trainer nurses to discern existing issues and identify a procedure amenable to transition into an AR format [24]. We then developed and implemented an AR-based educational program encapsulating two distinct procedures. We surveyed and interviewed trainees, focusing on technology acceptance and usability.

Figure 1. Overall process of the adoption of augmented reality into nursing education based on the Kern 6-step framework [22]. AR: augmented reality; ECMO: extracorporeal mechanical oxygenation.



Stage 1: Problem Identification

In this foundational stage, we endeavored to identify core problems through a general needs assessment, employing two primary approaches: engaging in interviews with training nurses and reviewing the extant literature [24-27].

The interviews, conducted with nurses from the nursing education department, were based on a semistructured format and were held online or offline depending on participant preference. Voice recordings ensured the precise capture of data shared during these interactions.

In addition to the interviews, we explored previous studies with the aim of harvesting insights and identifying common issues found within the existing research landscape, thereby anchoring our findings in a robust context of existing knowledge [28].

Stage 2: Needs Assessment

Upon conducting the interviews in stage 1, we recognized the challenges endemic to conventional educational methods as identified by educators. We investigated possible solutions to these challenges, and found the need for feedback through remote supervision, especially regarding certain devices. We further identified key elements that should be considered in the development of the educational program. This stage also served to validate our problem identification process.

Stage 3: Goals And Objectives

We defined our goals through collaboration between trainers and researchers, focusing on improving access and proficiency with complex medical equipment.

Stage 4: Educational Strategies

Step 1: Selecting Appropriate Technology

With the imperative for hands-on practice in nursing education, AR was chosen to enable nurses to interact with virtual medical devices within a realistic clinical setting [29]. AR's ability to superimpose digital models onto the physical world allows for a highly interactive and immersive learning experience without the traditional constraints of location, time, or physical resources [30]. This aligns with our goal to empower self-directed learning, permitting nurses to engage in practical education at their own pace and convenience [31].

Step 2: Developing Educational Material

Navigating through the lens of self-directed learning and hands-on practice, we considered AR options that could facilitate tangible interaction with 3D objects. The development of materials required a detailed comprehension of the unique needs of nurses and the incorporation of AR content to support self-directed learning.

Step 3: Preparation of the Educational Environment

To facilitate a high-fidelity learning experience, our AR-based educational program was set within the hospital's simulation laboratory. A designated area within the lab was prepared, encompassing a minimum of 3×3 meters to provide trainees with sufficient room to maneuver and interact with the virtual elements without spatial constraints. To ensure uninterrupted delivery of our AR-based educational program, we utilized five HoloLens 2 devices. This approach was adopted to mitigate against battery and overheating issues that could disrupt the learning process. This setup was optimized to allow multiple nurses to receive training at the same time, promoting efficient learning throughout while maintaining an individualized, hands-on experience.

Stage 5: Implementation

We recruited the participants through an advertisement posted on the hospital's internal internet network. Our goal was to enroll a minimum of 10 participants for each session to ensure a dynamic and interactive learning environment while still allowing for personalized instruction. We designed the sessions to accommodate up to five nurses at a time, which was determined as the optimal number for both effective learning and space utilization within our AR setup. This small-group approach not only facilitated focused attention from the instructors but also ensured that each participant could engage deeply with the AR modules.

To maintain a high standard of education and safety, we appointed two experienced supervisors for each training session. These supervisors were selected based on their expertise in intensive care procedures and their familiarity with AR technology. Their role was to provide immediate assistance and feedback, ensuring that any technical issues could be addressed without disrupting the learning process. They were also tasked with observing the sessions to gather informal feedback, contributing to the continuous improvement of the program.

Stage 6: Evaluation

This study was conducted at a large academic tertiary hospital in Seoul, Korea, which accommodates more than 3100 nurses and 2000 inpatient beds. The research provided education to intensive care nurses and included a postsession survey and semistructured interview.

Ethical Considerations

The Institutional Review Board of Samsung Medical Center approved the study design (SMC-2022-08-058 and SMC-2022-08-079), and all trainers and trainees provided written informed consent before participating in the study, ensuring ethical adherence throughout the research. To protect the participants' privacy and confidentiality, all data collected during this study were anonymized or deidentified. Stringent data protection measures are in place, including the use of secure, encrypted data storage systems accessible only by authorized personnel. These precautions are designed to safeguard sensitive information and maintain the integrity of the data. Participants were compensated for their time and contribution. Each participant received 30,000 KRW (~US $22) upon completion of their involvement in the study. This compensation was intended to acknowledge their valuable time and effort and to offset any inconvenience associated with participation. The compensation structure was clearly communicated to all participants prior to their enrollment and was administered transparently to ensure fairness.

Outcome Measures of the Survey

Upon completion of the educational program, participants were asked to fill out a questionnaire evaluating their user experience. This evaluation was based on the theories of self-directed learning and hands-on practice, including questions on personal characteristics, job satisfaction, and appropriateness. To evaluate the AR program's acceptability and usability, we employed the System Usability Scale (SUS) and the Technology Acceptance Model (TAM) [20,32,33].

We chose the SUS for its proven reliability and efficiency across various technologies. The SUS is widely used across various domains, including software, websites, and medical devices, to assess overall user experience. Moreover, it has been validated in hospital environments and shown effectiveness with small sample sizes. The SUS consists of 10 simple questions presented in a 5-point Likert-scale format, assessing both positive and negative aspects of the system, with total scores ranging from 0 to 100 [34,35]. The TAM was selected for its emphasis on understanding user acceptance of information technology [16,36,37]. We adapted the TAM-based survey questions to fit the context of AR nurse education, informed by various relevant studies [24,26,27,38]. In contrast, the SUS was employed in its unmodified form. In addition, we conducted a correlation analysis between the TAM and SUS elements [37,39].

Outcome Measures of Interviews

Nurses who responded to the questionnaire were selectively screened for their willingness to participate in further interviews. These interviews were semistructured and guided by nursing education theories from previous studies. The format allowed flexibility, permitting up to two additional questions based on the responses of the interviewees.

Statistical Analysis

The statistical analysis was performed using R software (version 4.3.2). Continuous variables are expressed as either mean (SD) or median (IQR), depending on their distribution, while nominal variables are expressed as counts (n) and percentages (%). We performed a correlation analysis to examine the relationship between the TAM and SUS using survey data.

Results

Stage 1: Problem Identification

Overview

We obtained interview results from four nurses who are trainers and operators in the nursing education department. The insights garnered from the interviews are summarized below and detailed in Table 1.

Table 1. Key considerations in augmented reality (AR) education development as expressed during trainer interviews.

Category	Key details	Core implications
Educational needs and challenges	Training requirements necessary for handling advanced medical equipment; aligning AR educational content to complement the features of specific medical devices; adapting training modules to meet the unique demands precipitated by the COVID-19 pandemic; implementing streamlined training processes for the rapid acclimatization of new nurses; addressing the limitations inherent in conventional training techniques; tackling the deficit of hands-on training equipment in nursing training	Imperative for AR solutions in bridging training disparities and responding to progressive requirements
Program development and strategies	Tailoring educational programs to align with the diverse experience levels of nursing professionals; standardizing the phases of training to ensure uniformity and consistency in educational outcomes; formulating well-structured and strategic plans for nursing training; ensuring efficient and effective distribution and management of training equipment and resources	Criticality of a holistic design and meticulous implementation in AR training for optimal efficacy
Challenges and future concerns	Addressing trainees' physical challenges, such as the necessity to wear glasses or masks, in the training environment; guaranteeing the safety and appropriateness of both the devices and venues utilized for training; modifying AR training methods to be inclusive and effective for older nursing personnel; integrating strategies within training programs to manage and reduce trainee fatigue effectively	Recognition of and addressing present and prospective hurdles for continuous advancement in AR training

Requirement of Education in Difficult-to-Use Devices

Using difficult-to-use medical devices in health care can pose a significant challenge for medical staff due to the increased risk of errors, negatively impacting patient outcomes. Proper education on these devices is essential to ensure that medical staff can use them safely and effectively.

Lack of Resources: Space, Instructor, Time, and Cost

The lack of education resources in health care can be a significant challenge for health care organizations and medical staff [15]. Education is essential to ensure that health care professionals possess the necessary knowledge, skills, and abilities to provide safe and effective care to patients. However, the interviewees mentioned that many health care organizations face barriers in providing adequate education resources to their staff, which can negatively impact patient outcomes.

Another challenge is the lack of adequate education time. Health care professionals are often required to work long hours, and finding time to attend education sessions and complete the necessary course work can be difficult. This lack of time can make it difficult for health care organizations to provide education tailored to the specific needs of their staff.

Stage 2: Needs Assessment

Following the interviews, we identified crucial factors to consider when selecting educational topics. Educators highlighted the significant challenges of limited access to educational devices and instructors. Additionally, they emphasized the necessity for education in technically demanding skills. Trainers expressed a preference for educational topics that required hands-on practice. Their reasoning is grounded in the knowledge that complex devices are frequently used in treating patients with critical illnesses. The competence of nurses in operating these devices directly impacts patient outcomes. The responses from trainers and operators related to needs are summarized in Table 1.

Stage 3: Goals and Objectives

Selected Objectives

Based on the interview results, extracorporeal membrane oxygenation (ECMO) machines and ventilators were selected as the objectives for training owing to their complexity and difficulty of use. Ventilators were selected as important yet challenging devices to master. The complexity of ventilators, compounded by the multitude of lines and connections involved, can pose challenges for nurses with limited experience.

By contrast, an ECMO machine is a high-risk medical device that is essential for patients with COVID-19. When the alarm of an ECMO machine sounds, nurses must promptly find a solution. However, given its rarity, even experienced nurses may not have encountered this situation. Nevertheless, as this could pose a risk to the patient, appropriate education was deemed necessary, and therefore use of the ECMO machine was selected as the problem scenario for this evaluation.

Selected Goals

Our aim was to develop a sustainable AR-based educational program that could offer numerous benefits to trainers and trainees. These benefits include enhanced engagement and motivation, interactive and immersive learning experiences, and the facilitation of personalized learning. Key considerations for developing such a sustainable AR-based educational program encompass designing for scalability and accessibility, and incorporating user feedback to enhance the program in its maintenance and operation over time.

Stage 4: Educational Strategies

Step 1: Development of an AR-Based Educational Program

The ECMO machine educational program comprises 45 slides divided into four parts, each detailing the operation of the machine, managing machine disruptions, responding to "low battery" alarms, and addressing the loss of flow signal ("SIG") alarm. Each part includes approximately 8-10 steps, guiding trainees on how to manage each situation effectively.

The ventilator program is composed of three parts encompassing a total of 46 slides. Each part involves 26 steps related to ventilator settings and preuse inspections, as well as seven steps for application, alarm configuration, and educational content evaluation. The education process involves checking supplies, power sources, wall oxygen and medical gas connections, and exhalation cassette connections; powering on the device; performing preuse checks; connecting test tubes; selecting the target and application method; turning on the humidifier; configuring the mode and parameters; connecting the patient to the system; monitoring after patient application; and setting alarms.

Step 2: Adoption of Innovative Technology

The AR-based education was performed with a Maquet Servo-I mechanical ventilator and the RotaFlow II System Permanent Life Support ECMO machine from Getinge. We attempted to incorporate a 3D guide for hands-on practice and used videos to enhance understanding. The AR-based educational program was developed using the Microsoft Dynamics 365 Guides program. The program's content was delivered to users through a Microsoft HoloLens 2 device.

Step 3: Operation Plan

The previously designated simulation laboratory was successfully used during the AR-based educational program. The allocated space for the program proved sufficient, with each trainee having access to the minimum 3×3 meters space as planned [40]. This spatial arrangement allowed for unimpeded movement and interaction with the AR components, which was critical for the immersive learning experience.

In practice, the ventilator and ECMO machine simulations were conducted without any spatial constraints, enabling a total of 28 trainees to complete the training per the session schedules. The effective use of space was evidenced by the trainees' ability to perform the necessary tasks and their reported comfort level during the training sessions.

Stage 5: Implementation

The AR-based educational program platform was operational for a period of 2 months, with education sessions scheduled from 9 AM to 5 PM. This schedule allowed nurses to select their preferred date and time within this interval. To facilitate the program's implementation, we used five HoloLens 2 devices, along with two laptops for supervisor screen connections and two large screens for the research environment. Throughout the research, a total of 22 trainees actively engaged in the education sessions. The trainees' screens, as viewed through the HoloLens 2 devices, were immediately visible to the trainer, enabling real-time progress monitoring. Additionally, trainees were encouraged to request assistance if they encountered any difficulties during the session.

Stage 6: Evaluation

Participants

Training sessions were conducted by two trainers and two operators for the 28 nurses in the ICU from January 1 to February 3, 2022. Twenty-four nurses participated in the survey, 11 of whom took part in an in-depth interview. They were trained either in ventilator or ECMO machine usage with an even distribution across both groups. The participants' baseline characteristics are presented in Table 2. The median work experience was 3 (IQR 0-6.25) years with a mean of 3.75 (SD 3.90) years. There was a predominance of female participants (17/24, 71%). All participants belonged to the general nursing field with a slight majority working in the medical ICU compared to the surgical ICU (Table 2).

Additionally, all participants (24/24, 100%) owned smartphones and the majority (23/24, 95.83%) possessed either a tablet PC or laptop. Prior to the instruction, 13 (54%) nurses had previous experience with a head-mounted display.

Table 2. Demographic and clinical characteristics of the surveyed nurse trainees (N=24).

Characteristics	Trainees, n (%)
Method trained on	
ECMO[a]	12 (50)
Ventilator	12 (50)
Sex	
Male	7 (29)
Female	17 (71)
Medicine specialty	
Internal medicine	15 (63)
Surgical department	9 (38)
Experience (years)	
<1	5 (25)
1-2	3 (15)
3-4	2 (10)
5-6	2 (10)
≥7	3 (15)

[a]ECMO: extracorporeal membrane oxygenation.

Comparison of SUS and TAM Scores

In the usability test, the items "I think that I would like to use this system frequently" and "I don't think the system is unnecessarily complex" received the highest rating of 4.38 out of a possible 5, while the lowest-rated item, "I thought there was too much inconsistency in this system," received an average score of 1.83. The responses concerning technology acceptance were categorized into four areas according to the TAM: perceived usefulness (PU), perceived ease of use (PEU), perceived enjoyment (PE), and intention to use (IU). The survey included 15 questions scored on a 7-point scale. The item with the highest score was "It is fun to use," scoring 6.71, while the lowest-rated item was "It is easy to use," scoring 5.17. In further survey results, factors such as age, sex, department of work, and years of work did not impact satisfaction with the education or usability. All response results for the survey are provided in Multimedia Appendix 1.

Correlation of Usability and Acceptance

Our correlation analysis revealed varying degrees of association between SUS and TAM factors. For instance, there was a strong correlation between PU and IU and a moderate correlation between PE and PU. However, the correlation between PEU and IU was not significant (Table 3).

Table 3. Correlation between the Technology Acceptance Model–based survey items and System Usability Scale (SUS).

Variable	UE[a] (SUS)	PU[b]	PEU[c]	PE[d]	IU[e]
UE (SUS)					
r	1	0.2	0.34	0.15	0.22
P value	—[f]	.50	.12	.45	.30
PU					
r	0.2	1	0.2	0.69	0.76
P value	.50	—	.50	<.001	<.001
PEU					
r	0.34	0.20	1		0.31
P value	.12	.50	—	.34	.33
PE					
r	0.15	0.69	0.32	1	0.72

[c]PEU: perceived ease of use.
[d]PE: perceived enjoyment.
[e]IU: intention to use.
[f]Not applicable.

Insights From Participant Interviews

Four participants completed interviews related to their experiences with the AR-based educational program. Key insights from these interviews have been collated and are summarized in Table 4. We present a curated selection of interview responses that most effectively capture the key insights. These selections were thoroughly chosen for their relevance and ability to represent the broader findings of the study.

Overall, the evaluation of the AR-based education was positive, with participants indicating that AR could enhance their actual clinical performance. AR technology is particularly well-suited for individuals interested in self-directed or hands-on learning theories. Nurses were found to be open to education using innovative technology. When asked if they needed assistance with the curriculum, no participant responded negatively regarding the content. However, some participants did express a need for help in adapting to new devices and technologies.

Table 4. Trainees' feedback after augmented reality (AR) implementation in the training program.

Category and subcategory	Details
Motivation	
Intrinsic motivation	Interest in the integration of AR into educational settings; desire among learners for practical experience with medical devices; expectations that AR technology will significantly improve learning efficacy
Reasons for participation	Influence of colleague recommendations; curiosity about AR teaching methods; specific needs related to own job
Existing issues	Noticing varying standards in educational quality; underscoring the need for improvement; necessity to establish standardized training procedures and protocols; need for training programs to be customized to individual learning styles and needs
Learning preferences	
Preferred learning method	Balancing traditional (54.5%) and self-directed (45.5%) learning approaches; valuing feedback and interaction in traditional learning; preference for flexibility and pace in self-directed learning
Face-to-face versus nonface-to-face	Equilibrium between face-to-face (54.5%) and remote learning (45.5%); diverse preferences shaped by feedback, comfort, and flexibility
Feedback	
Practical use	Majority opinion holding that AR technology is beneficial for skill development; mixed opinions regarding the real-world applicability of AR in professional settings; varied levels of expectation regarding the use of AR devices in educational contexts
Training experience	Recognizing the benefits of AR in providing realistic scenarios, allowing for self-directed learning, and enabling repeated practice; challenges include unfamiliarity with AR, focus on operation over content, and limited interaction
Content and support	General satisfaction with AR content amid comparisons to traditional methods; requirement for technical support and assistance in AR training
Comparative analysis and outlook	AR's superiority in learning pace, error identification, and training repetition over conventional methods; challenges in mastering AR operation and content depth; mixed perspectives on AR replacing traditional methods (viewed as supplementary); AR's efficacy in specific scenarios; considered resource-intensive for broad implementation; potential for enhancing self-directed and iterative learning
Future considerations	
Target demographics for AR training	Target new nurses, individuals lacking device experience, and department transfers; however, limited relevance for experienced nurses
Benefits of self-learning with AR	Reduced pressure, time efficiency, review flexibility; utility in learning uncommon scenarios and repeatable sessions
Concerns with self-learning	Limitations of AR training in actual clinical settings; lack of communal learning opportunities in AR environments; concerns over system errors and device quantity limitations

Discussion

Principal Results

The principal findings of this study provide valuable insights into the strategic translation of conventional critical nursing education to AR-based education platforms in the use of difficult-to-use medical devices [41]. Through interviews conducted with trainers before program development, the study successfully identified the specific needs and requirements of trainers in critical care nursing education. The study employed AR-based educational technology to enhance self-directed learning and hands-on practice.

In the educational strategies employed, the study leveraged the unique features of AR to facilitate self-directed learning. By offering interactive and self-controlled learning experiences, AR empowered trainees to take ownership of their learning process. The program incorporated instructional materials and modules that allowed learners to explore and acquire knowledge at their own pace, fostering a sense of autonomy and self-guided learning. The use of AR also enabled real-time feedback and assessment, allowing learners to track their progress and identify areas for improvement [29].

Through the overlay of 3D objects and virtual models onto real-world settings, trainees engaged in simulated scenarios closely resembling authentic ICU environments. This hands-on component of the program enabled learners to apply their knowledge and skills in realistic contexts, promoting an understanding of the subject matter and the development of critical thinking and problem-solving abilities.

This study highlights how AR technology significantly contributes to the success of self-directed learning and hands-on practice. The utilization of AR technology facilitates active engagement, learner-centeredness, and skill development, thereby enhancing the overall effectiveness of critical care nursing education. Moreover, we provide useful insights based on the perspectives of trainers and operators of the platform. The inherent nature of education often necessitates a lower number of educators compared to learners. The main strength of our study thus lies in presenting an infrequent perspective of educators, a viewpoint seldom encountered within the large-scale hospital setting.

Comparison With Prior Work

AR technology has been extensively explored in areas related to nursing education [42] such as surgical simulation [43], anatomy education [20], and patient safety education [44]. However, it is worth noting that this study represents the first investigation into the use of AR for replacing a conventional educational program in the use of difficult-to-use devices such as an ECMO machine and mechanical ventilator specifically within the critical care nursing field. By incorporating AR into these fields, this study pioneers the integration of innovative approaches in nursing education.

Limitations

This study, being characteristic of a pilot study to identify and apply new educational methods, has the limitation of a restricted number of participants. In further research, a larger sample size could be recruited to identify factors influencing user acceptability and to enhance usability, leveraging insights for more effective implementation.

Implications

This study highlights the implications of AR in future research and practice. The findings suggest the need for longitudinal studies to assess AR's long-term impact on clinical performance and patient outcomes, and to explore its scalability and cost-effectiveness compared to traditional training. Practically, the results of our study indicate that institutions adopting AR should invest in technical support and training and consider integrating AR as a supplementary tool in curricula for a blended learning approach.

Conclusions

This study provides insights on the development, launch, and operation of an AR-based medical educational program. The study suggests that an AR-based educational program can be an alternative to compensate for insufficient resources for conventional critical care nursing education. Further research can be conducted to compare the effectiveness and feasibility of this program with other AR-based educational programs and traditional nursing educational programs.

Acknowledgments

This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HI23C038700). We would like to express our sincere gratitude to all the individuals who contributed to the successful completion of this study. Primarily, we would like to thank the nursing education chiefs for their valuable insights and participation in the interviews. We are also grateful to the nurses who willingly participated in the study, sharing their experiences and providing valuable feedback. Additionally, we extend our appreciation to the operators who assisted in the implementation of the augmented reality–based educational program. The authors would like to thank Seungheon Choo for his invaluable assistance with the English proofreading of this manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Home gardens worldwide provide sustenance, economic support, and access to fresh produce and promote household well-being, health, self-sufficiency, and food security. However, they face significant challenges worldwide and necessitate innovative promotion approaches. Serious video games have proven effective in promoting agricultural knowledge. However, more research is needed on the persuasive potential of agriculture games to influence players' thoughts, attitudes, and behaviors. This provides an opportunity to examine the impact of persuasive games on promoting home gardening among novices.

Objective: This study aims to describe the design and development of Farmily, a persuasive video game promoting home gardening among novices. In addition, it evaluated the effectiveness of Farmily and compared its impact with that of a traditional home gardening workshop. Furthermore, the study explored how game enjoyment relates to the game's outcomes.

Methods: A randomized controlled trial with 50 novice gardening participants aged 20 to 50 years was carried out. Participants were randomly assigned to a control group (1.5-hour workshop) or an experimental group (1.5-hour Farmily session). Pre- and postintervention assessments were conducted. We evaluated Farmily's impact on knowledge, attitudes, perceived self-efficacy, and intentions regarding initiating home gardens. In addition, we investigated the user enjoyment and its relationship with the game's effect outcomes.

Results: The experimental group significantly improved their knowledge (t_{24}=4.26; *P*<.001), attitude (z_{24}=2.98; *P*=.003), self-efficacy (t_{24}=2.6; *P*=.02), and intention to initiate home gardens (z_{24}=4.15; *P*<.001). The experimental group showed similar effectiveness in knowledge transfer (t_{24}=–1.71; *P*=.09) and a more significant impact on attitude (z_{24}=2.73; *P*=.006), self-efficacy (t_{24}=2.21; *P*=.03), and intention to start a home garden (t_{24}=–5.33; *P*<.001) than the control group. Farmily was well received by the intervention group, generating high enjoyment. Furthermore, user enjoyment substantially correlated with user attitudes (r_{23}=0.72; *P*<.001) and self-efficacy (r_{23}=0.67; *P*<.001), yet no discernible association was observed among user enjoyment, knowledge (r_{23}=0.26; *P*=.20), and intention (r_{23}=0.06; *P*=.77).

Conclusions: Evidence indicates that Farmily appears to be a viable tool for promoting home gardening among novices in the short term. Farmily demonstrated similar effects in knowledge improvement to those of a traditional workshop and had a more significant impact on the other variables. In addition, we found that the player's gaming experience positively relates to the player's attitudes and self-efficacy. A well-powered randomized controlled trial with more diverse samples and extended follow-up periods will be conducted to establish the long-term efficacy of Farmily and gain a deeper understanding of the influence of enjoyment on game outcomes.

KEYWORDS
serious video game; persuasive game; home gardening; knowledge; attitude; self-efficacy; intention

Introduction

Promotion of Home Gardening

Home gardens, a long-standing tradition of small-scale food cultivation near human settlements [1], remain a cornerstone of agriculture, providing essential sustenance and economic support for families worldwide [2]. These gardens, cultivated for centuries, serve multifaceted purposes within local food systems. Alongside economic benefits such as financial savings and income generation, they provide year-round nutrition and access to fresh produce and contribute to biodiversity conservation [2-4]. In addition, home gardens contribute to ecological production, enhance esthetics, and promote sustainable urban development [5]. Moreover, maintaining and using home gardens contributes significantly to household well-being by promoting psychological and physical health and fostering familiar and social connections and bonds [6]. Another significant benefit is fostering self-sufficiency as individuals cultivate plants or food crops at home to meet their sustenance needs, thereby reducing dependence on external sources [7]. This characteristic plays a crucial role in bolstering food security [8], a role that was particularly emphasized during the COVID-19 pandemic [9]. Due to these advantages, home gardening initiatives have expanded to include elementary schools [10], urban areas, and household environments [11]. They remain a valuable pursuit even for economically active individuals who can afford groceries.

Despite the global significance of home gardens, many people are not interested or hesitant to start one [12], contributing to their decline [13], a trend particularly concerning in countries such as Mexico [14]. Various strategies have been proposed to promote home gardening, ranging from campaigns highlighting its benefits to educational initiatives offering guidance through manuals, courses, workshops, and guides [15]. However, these initiatives often focus on individuals already motivated to start gardening, potentially missing the chance to inspire and engage newcomers. Furthermore, these strategies encounter challenges inherent to the multifaceted nature of home gardening, including the necessity to develop skills; address concerns; overcome motivation issues [16,17]; acquire interdisciplinary knowledge in fields such as biology, chemistry, and economics [10]; and achieve a balance between theoretical learning and hands-on activities [18].

To bridge the gap between promoting home gardening and its adoption, innovative strategies are essential to attract a diverse audience, motivate and empower individuals, and provide practical learning opportunities. It is crucial that these strategies mainly focus on novices—individuals who are open to learning about gardening but may not be strongly motivated to pursue it actively. These individuals often lack extensive knowledge, experience, and confidence in gardening and may not fully grasp its benefits. This situation presents an opportunity to develop accessible and engaging tools that inspire, educate, build confidence, and foster sustained interest in home gardening. Persuasive video games provide a promising platform to enhance users' knowledge, skills, and experiences through interactive platforms [19] and foster positive changes in perceptions, attitudes, or behaviors [20,21].

Persuasive Video Games

Persuasive video games, also known as serious games for change or persuasive games, aim to actively engage players while promoting positive changes in their thoughts, attitudes, feelings, actions, or behaviors [20-22]. They integrate interactive gameplay, narrative elements, educational content, and persuasive strategies to foster attitude and behavior change. Despite their serious intent, these games prioritize enjoyment and engagement, leveraging the immersive nature of video games to captivate players and sustain their interest [23]. They often include informative content relevant to the issue, offering players opportunities for learning and reflection during gameplay [24]. These games may use procedural rhetoric through interactive gameplay dynamics to convey persuasive messages effectively [22] and can use exocentric or endocentric approaches to engage and motivate players [24]. Successful play encourages players to develop a deeper understanding beyond the game, potentially influencing their behavior afterward. However, the effectiveness of these games hinges on game features, player characteristics, use context [25], and the balance of persuasive strategies [21].

Persuasive video games are a powerful tool for driving social change [26]. They are studied extensively for their ability to promote attitude and behavior changes across various issues such as politics, society, environment, and health [21]. They address social problems such as attitudes toward homelessness [27], humanitarian aid willingness [28], and workloads [20] while also tackling health issues such as physical activity, nutrition, and disease management [21]. Specific games target smoking cessation [29] and medication adherence [30]. Despite their widespread application, research shows mixed results on their impact, with some studies confirming effectiveness and others not, leading to inconsistent findings [20,21,31]. A systematic review indicated positive or partially positive outcomes [21], but effectiveness varied across studies, underscoring the need for rigorous evaluation across diverse contexts and user profiles [20]. Current research often focuses on overall impacts rather than specific game or user characteristics [31], necessitating further studies on how game features affect effectiveness, especially the effect of user enjoyment [32].

Persuasive Video Games for Agriculture

Most serious video games for agriculture have been designed as educational tools [33]. Explicitly designed persuasive games are scarce; only a few studies have evaluated their persuasive effects. The educational games cover various aspects of agriculture and vegetable cultivation, including genres such as role-playing games and farm simulators. Examples include "Farmtasia" [34], "Little Botany" [35], "Herbopolis" [36], and Serious Game for Agroecology Learning [37]. They offer valuable learning experiences in farming practices, sustainable agriculture, herbal medicine agriculture, and ecological awareness, leading to knowledge enhancement. However, there need to be more games specifically focusing on home gardening [33]. Another group of studies aims to raise awareness of agriculture-related issues. "AgriVillage" [38] focuses on environmental concerns in agriculture, including the effects of fertilizers and deforestation on water sources and weather patterns. "RebEarth" [39] promotes awareness of hydroponics. Furthermore, individuals who are agricultural novices are often overlooked by current serious video games for agriculture [33].

Among the studies evaluating the persuasive effects of serious agricultural games, an example is "Game of Piglets" [40], a virtual pig farm that allows students to practice external biosecurity and farrowing management procedures. This simulation and adventure game emphasizes core competencies such as farrowing aid, identifying unwell sows after farrowing, maintaining aseptic conditions during surgeries, and ensuring an optimal piglet environment. These competencies are developed through tasks closely resembling real-life scenarios in pig farms. Evaluation results indicated improved perceived self-efficacy among players. Another instance is "MahindiMaster" [41], a serious game simulating crop yields based on farmers' choices from various input options. These yields are customized using crop model outputs leveraging plot-level soil samples and historical weather data. The game allows farmers to experiment with 3 different fertilizers. Evaluation outcomes revealed positive shifts in players' beliefs and fertilizer use on their crops. While the evaluation results indicate positive impacts and the viability of using agriculture-focused serious video games to change players' attitudes and behaviors, the persuasive potential of agricultural video games remains unexplored. It prompts questions about their effectiveness in promoting home gardening among novices.

Inspired by the need for innovative strategies to promote home gardening among novices and recognizing the potential of persuasive video games to influence user knowledge, attitudes, and behaviors, this study addressed existing research gaps in persuasive serious games for home gardening. In total, 3 primary research questions guided our investigation. The first 2 questions focused on the effect of a persuasive game on promoting home gardening among novices:

- Can a persuasive video game encourage novices to engage in home gardening?
- Does a persuasive video game have a more significant impact on changing novices' knowledge, attitudes, self-efficacy, and intentions than a traditional course?

In addition, our investigation was guided by the following primary research question that sought to understand how the enjoyment derived from the game influenced its effectiveness:

- How does the enjoyment experienced by players of an agriculture-focused persuasive video game relate to the game's effects?

Objectives and Hypotheses

This study aimed to design and develop a persuasive video game promoting home gardening among novices called Farmily (Farm+Family) and evaluate its effects.

On the basis of the potential of persuasive video games to promote home gardening, we formulated the hypotheses that Farmily players would exhibit superior outcomes in the following areas after playing (hypothesis 1): home gardening knowledge (hypothesis 1A), attitudes toward home gardens (hypothesis 1B), self-efficacy in home gardening (hypothesis 1C), and intention to start a home garden (hypothesis 1D).

In addition, based on the idea that a persuasive video game offers more effective elements for promoting home gardening among novices compared to a traditional course, we established the hypotheses that Farmily players would demonstrate superior outcomes compared to traditional course attendees in the following areas (hypothesis 2): home gardening knowledge (hypothesis 2A), attitudes toward home gardens (hypothesis 2B), self-efficacy in home gardening (hypothesis 2C), and intention to start a home garden (hypothesis 2D).

Finally, based on the premise that game features, particularly user enjoyment, significantly relate to game outcomes, we formulated the hypotheses that the player's gaming enjoyment is positively related to (hypothesis 3) home gardening knowledge (hypothesis 3A), attitudes toward home gardens (hypothesis 3B), self-efficacy in home gardening (hypothesis 3C), and intention to start a home garden (hypothesis 3D).

Methods

Study Design

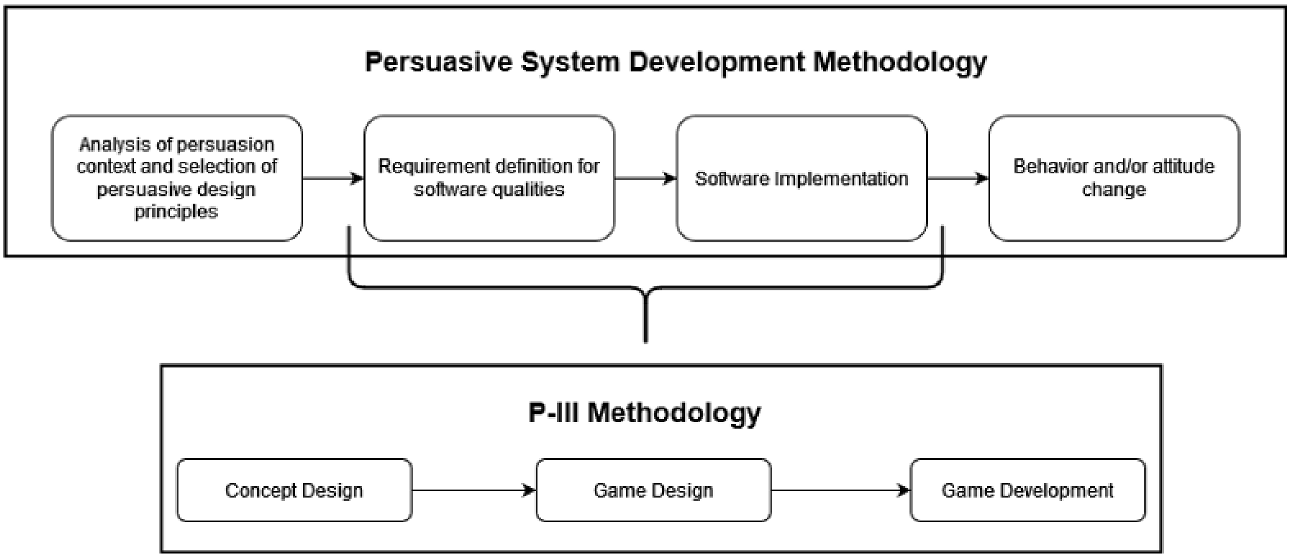
This study was divided into 2 main parts. The first part focused on designing and developing the video game Farmily. The second part involved conducting a randomized controlled trial (RCT) to assess the impact of Farmily and validate the formulated hypotheses. In the following sections, we provide a detailed description of the Farmily video game.

Farmily Video Game

Design and Development

To create Farmily, we integrated 2 methodologies (Figure 1): the persuasive system design (PSD) methodology [42] and the player-centered, iterative, interdisciplinary, and integrated (P-III) methodology [43]. The PSD methodology guides the design of persuasive systems [42], and accordingly, we followed four key steps aligned with persuasive principles. In step 1, we analyzed the context of persuasion and selected appropriate principles and techniques for Farmily. Steps 2 and 3 focused on defining and developing the game, whereas step 4 involved experimentation to evaluate its effectiveness.

Figure 1. Methodology for the design and development of Farmily. P-III: player-centered, iterative, interdisciplinary, and integrated.



During steps 2 and 3 of PSD, given the need to develop a specific persuasive system—a persuasive video game—we used the P-III methodology [43] tailored for serious game design. The P-III methodology emphasizes player-centered design, iterative development, and interdisciplinary collaboration. Following the P-III methodology, we engaged experts in human-computer interaction, agriculture, horticulture, education, and software engineering. In stage 1, the concept design phase, extensive research on home gardening informed the definition of user tasks through co-design sessions and expert consultations. Progressing to stage 2, the video game design phase, we used storyboards, focus groups, and paper prototypes, refining the game iteratively based on continuous feedback. Stage 3, the development phase, involved iterative prototyping and testing. We conducted 21 work sessions, incorporating multiple refinement cycles and expert testing sessions.

Theoretical Base and Persuasive Techniques

Farmily is based on the social cognitive theory by Bandura [44,45], which provides valuable insights into individual learning, development, and behavior maintenance in social contexts. This theory highlights the dynamic interplay of personal factors (cognition, beliefs, skills, and affect), environmental factors (social norms, institutions, and cultural influences), and behavioral factors (observable actions and responses) [44,45]. This theory proposes that individuals shape their environments through behavior, and vice versa, environments influence behavior and cognition. Learning, as per this theory, happens through direct experience and observing others [45]. Actions and outcomes offer crucial feedback on behavior appropriateness, with rewards encouraging desirable behaviors and punishments discouraging them. Furthermore, this theory emphasizes self-regulatory processes, which involve activating and sustaining behaviors, cognitions, and emotions directed toward achieving goals. It also highlights various motivational processes, including goals, progress evaluations, outcome expectations, values, and social comparisons. A key concept in the theory by Bandura [44,45] is self-efficacy, which pertains to one's belief in their capacity to achieve desired outcomes through specific actions. Self-efficacy significantly impacts motivation, goal setting, and persistence, with individuals who possess high self-efficacy more inclined to pursue challenging objectives and persist despite obstacles.

Drawing from the social cognitive theory by Bandura [44,45] and the PSD principles by Oinas-Kukkonen and Harjumaa [42] and Fogg [46], Farmily integrates persuasion techniques. Farmily's persuasion techniques are classified into primary support, dialogue support, credibility support, and social support, as detailed in Table 1. These strategies aim to engage players' intellect and motivation, guide behavior, and encourage their interest in starting home gardens. They have proven effective in persuasive video games such as "PowerHouse" [47] and "Smoke?" [21,48].

Table 1. Persuasive techniques of Farmily.

Name	Description
Primary support techniques	
Reduction	The game incorporates a virtual environment for family garden ownership and management that simplifies home garden maintenance.
Tunneling	The game offers a structured progression system with increasing complexity across levels, introducing new variables for users to understand.
Tailoring	Tailored knowledge by dividing levels into 3 difficulty tiers: easy, medium, and hard. Users unlock progressively more advanced and comprehensive information tailored to their learning needs as they advance.
Self-monitoring	The score and recommendation system helps players monitor their performance and receive guidance for improvement. This tangible evidence motivates them to persist in learning and practicing.
Simulation	Includes a home garden simulation mirroring real-life scenarios, helping players grasp cause-effect relationships between their actions and virtual outcomes.
Rehearsal	Provides a platform for simulating various home garden–related behaviors and activities. Through repetitive practice and self-monitoring, players enhance their self-efficacy and proficiency in gardening skills.
Dialogue support techniques	
Praise	Implements a praise system that offers positive reinforcement to players upon completing tasks or levels. Through motivational messages and rewards, the game aims to encourage continued gameplay.
Rewards	Incorporates rewards and motivators such as unlockable content and points to encourage continued play. For instance, users earn a trophy for completing the story mode and stars for each level, enhancing motivation and engagement.
Suggestion	The in-game recommendation system guides players in enhancing their gardening performance and achieving higher scores. Tailored suggestions empower players to improve and meet game objectives, boosting their self-efficacy and intention to apply gained knowledge to real-world gardening.
Liking	Meticulously recreates a home garden's visual and sensory experience, immersing players in a realistic virtual environment. This attention to detail enhances players' liking and connection to the game.
Credibility support techniques	
Trustworthiness	The game's gardening knowledge base is built on accurate and authentic information from reliable sources, such as books and manuals recognized and developed by Mexico's agriculture department and scientific papers sourced from reliable journals, ensuring its trustworthiness and reliability.
Surface credibility	The game's visual design and user interface are meticulously crafted to offer players a professional and credible experience.
Social support	
Social comparison	Including a leaderboard in the video game enables players to compare their scores and monitor the progress of other users. This feature fosters a competitive and social atmosphere that encourages engagement and interaction among players.
Competition	The video game allows players to compete against each other, striving to reach the top of the leaderboard and achieve the highest score. This competitive element enhances motivation and drives players to improve their performance.
Recognition	The game recognizes the top 5 players through the leaderboard, highlighting their achievements and establishing a sense of accomplishment. This acknowledgment rewards players and motivates them to continue their efforts and aim for higher rankings.

Description

Farmily is a 3D simulation single-player game available on desktop and Android platforms. It was developed using the Unity game engine (version 2021.3.8f1; Unity Technologies). The players guide and assist a virtual family in managing a home garden. The target users are individuals aged between 20 and 50 years who are novices in home gardening, chosen for suitability. This age range aligns with Mexico's economically active population (ages of 15 to 64 years) [49] and the gaming demographic [50], capturing a significant portion of gamers interested in home gardening. Variations in the age range do not significantly impact the study's relevant aspects. The game aims to convey messages such as gaining knowledge about home gardening, recognizing its importance and the enjoyment it generates for individuals and their families, understanding commitments and trade-offs, realizing accessibility and rewards, and acknowledging the multidisciplinary knowledge and risks involved.

Farmily consists of 3 sections: the "Main menu" (Figure 2), "Education" (Figure 3), and "Simulation" (Figure 4). In the main menu, players can register, access the leaderboard, adjust sound settings, and start a gaming session. The educational section is seamlessly integrated into the gameplay, offering tutorials on game mechanics and guidance on executing home gardening tasks both in the game and in real life. The simulation section encompasses the home garden simulation and all associated gameplay mechanics.

Figure 2. Screenshots of the main menu (top) and level selection (bottom). The game is presented in Spanish.

The game's difficulty gradually increases to enhance its educational and persuasive aspects. Farmily offers 20 levels divided into beginner (levels 1-8), medium (levels 9-14), and advanced (levels 15-20) tiers (Figure 2, bottom). Each tier presents challenges in crop yield, finances, and simulation complexity. The level goals include growing and harvesting crops, ensuring family participation, practicing sustainability, maximizing savings, and providing a comprehensive understanding of home gardening implications and benefits.

The game educates players on 12 recommended crops for daily consumption [51], empowering informed decisions and gardening optimization. In Farmily, each level follows a systematic progression—players start by preparing compost, clearing undergrowth, and watering and then plow an area spanning 1 to 40 m^2. Next, they plant seeds in nurseries, nurture them, and transplant them. Subsequently, players water, fertilize, and apply pesticides as needed to ensure crop health for harvesting.

Figure 3. Screenshots of the education section; home gardening phases (top) and tutorial menu (bottom). The game is presented in Spanish.

The game provides indicators for garden health, including a progress bar for the current month and phase, meters for overall garden health and sustainability, and progress bars for vegetable quantity (Figure 4, top). Detailed plot information, such as humidity and macronutrient levels, is also available. After harvesting all crops, players receive a rating from 1 to 5 stars based on factors such as harvested vegetables, family involvement, sustainable practices, financial economy, and self-sufficiency (Figure 4, bottom). These ratings unlock new scenarios, motivating players to improve and enhancing replay value. A home garden manual is a central hub for information on crops, fertilizers, pesticides, and game mechanics tutorials (Figure 3, top). Personalized recommendations based on player actions help optimize gardening strategies (Figure 4, bottom). A leaderboard fosters competitive excitement by allowing players to compare scores and aim for the top spot (Figure 2, top).

Figure 4. Screenshots of the simulation section; cultivation (top) and level evaluation with recommendations (bottom). The game is presented in Spanish.

Evaluation

Overview

In 2023, an RCT was conducted at a Mexican university, with written permission from the school administrators to conduct the trial at the school facilities.

Participant Recruitment

We used a convenience sampling approach by inviting 180 students from 9 academic groups to participate based on their availability and interest in the study. Participants were invited without previous information about their backgrounds or characteristics, ensuring a diverse representation across different scholar groups. On the day of the experiment, we verified that participants who agreed to take part met the inclusion criteria, which were (1) being aged between 20 and 50 years; (2) belonging to a family nucleus comprising at least 2 members; (3) having an interest in home gardening; (4) residing in Ciudad Guzmán, Jalisco, Mexico; and (5) having essential elementary-level reading and writing skills in Spanish. Exclusion criteria were applied to individuals who (1) currently or previously had a home garden, (2) had undergone a home gardening course, and (3) had vision or motor impairments that hindered their use of the video game on a PC.

Structure and Procedure

Individual participants were randomly assigned to either the control group (CG) or the experimental group (EG). Before the intervention (T_0), both groups completed 2 pretest questionnaires measuring their knowledge, attitude, self-efficacy, and intention to start a home garden (see the *Measured Variables* section). During the intervention, participants in the CG engaged in a 1.5-hour home gardening workshop facilitated by an expert in agriculture. The workshop provided participants with the same valuable information regarding the benefits, requirements, and activities associated with maintaining a home garden as that provided in the EG and Farmily. The expert presented the knowledge in a lecture format without hands-on experience with a home garden or interactive activities. This workshop mirrors the traditional way of fostering home gardening. In contrast, participants in the EG played Farmily for 1.5 hours. Finally, after the intervention period (T_1), the CG and EG participants completed the same questionnaires applied during the pretest. This posttest measurement served as a valuable indicator of any changes or improvements in these domains following the intervention. In addition to the posttest questionnaires, participants in the EG were also asked to provide feedback on their enjoyment of the video game using a questionnaire.

Measured Variables

The following variables were measured before (T_0) and after (T_1) the intervention: (1) knowledge about home gardening, (2) attitude toward home gardening, (3) self-efficacy in home gardening, and (4) intention to start a home garden. In addition, in T_1, we measured the users' enjoyment. Textbox 1 describes the measured variables. In the following paragraphs, we describe the methods used for their measurement.

Textbox 1. Description of the measured variables.

Knowledge about home gardening

- This is the comprehension level of a home garden's concepts and procedures.

Attitude toward home gardening

- Fishbein and Ajzen [52] define attitude as "an individual's positive or negative feelings towards realizing an objective behavior." In line with this, we defined *attitude toward home gardening* as "an individual's positive or negative thoughts about having a home garden."

Self-efficacy on home gardens

- Self-efficacy is "people's beliefs about their abilities to produce a certain level of performance that influences events that affect their lives" [53]. Given this concept, *self-efficacy in home gardening* was defined as "people's beliefs about their abilities to have a home garden with a certain level of performance that influences the events that affect their lives."

Intention to start a home garden

- Intention is "a person's motivation in the sense of their conscious plan or decision to exert effort to perform a behavior" [52]. On the basis of this concept, *intention to start a home garden* was defined as "the conscious motivation of a person to start a home garden."

Game enjoyment

- It is defined as "a person's perception and response as a result of using or anticipating using a product, system, or service" [54].

To evaluate participants' knowledge levels effectively, we developed a 23-item questionnaire with a home gardening expert, ensuring accuracy and relevance. The questionnaire items were strategically structured into 3 difficulty levels (easy, medium, and hard) designed to assess participants' understanding comprehensively. Each item provided 4 answer options, with only 1 correct answer. For example, sample questions included an easy query, such as "How many days does it take for a plant to germinate?"; a medium-level question, such as "Which of the following statements best describes the advantages of sustainable products?"; and a hard question, such as "What is a critical factor for achieving success in home gardening?"

To assess attitudes toward home gardens, self-efficacy in home gardening, and the intention to start a home garden, we developed a 14-item questionnaire. This questionnaire draws upon the attitude, self-efficacy, and intention scales from the Unified Theory of Acceptance and Use of Technology (UTAUT) [55]. The UTAUT questionnaire's validity has been established through rigorous testing and has been shown to account for 70% of the variance in intention [55]. Furthermore, the scale's reliability was demonstrated with a Cronbach α of 0.70 across all scales [55]. The attitude toward home gardens scale comprises 4 items, the self-efficacy scale includes 7 items, and the intention to start a home garden scale consists of 3 items. Each item is rated on a 5-point Likert scale ranging from "1—Totally disagree" to "5—Totally agree." Sample questions include "Are home gardens a beneficial idea?" (attitude toward home gardens), "Compared to other people, can I perform my home gardening activities correctly?" (self-efficacy), and "I plan to start a home garden in the next six months." (intention to start a home garden).

We used the EGameFlow questionnaire [56], a validated tool of 42 items, to assess user enjoyment. Comprehensive testing confirmed the questionnaire's validity, which was robust enough to account for 74% of the variance in learner enjoyment [56]. Moreover, the EGameFlow questionnaire exhibited strong reliability, boasting a Cronbach α of 0.942, signifying excellent internal consistency. In addition, it demonstrated good test-retest reliability [56]. The questionnaire items are categorized into 8 dimensions: concentration (6 items), clear goal (4 items), feedback (5 items), challenge (6 items), autonomy (3 items), immersion (7 items), social interaction (6 items), and knowledge improvement (5 items). Each item is rated on a 5-point Likert scale ranging from "1—Totally disagree" to "5—Totally agree."

Data Analysis

The data analysis was performed using the R software (version 4.3.0; R Foundation for Statistical Computing) on the Windows platform. A significance level of 5% (P<.05) was used to determine statistical significance. The normality of the numerical data was assessed using the Shapiro-Wilk test. Parametric tests were used for normally distributed data, while nonparametric tests were used for nonnormal data. Changes in knowledge within the same group were analyzed using a 1-tailed paired *t* test. A 2-tailed independent-sample *t* test was conducted to compare knowledge between groups. The Wilcoxon signed rank test was applied for questions with ordinal values, such as attitude, self-efficacy, intention, and user enjoyment. The 2-tailed paired *t* test was used to analyze differences from T_0 to T_1 in ordinal question scales within the same group assuming that the data followed a normal distribution. Alternatively, the Wilcoxon signed rank test was used. For comparisons between groups and when the data followed a normal distribution, a 2-tailed independent-sample *t* test was used. In the absence of normal distribution, a Mann-Whitney *U* test was conducted. The internal consistency of the user enjoyment scales was assessed using the Cronbach α. Finally, the bilateral Pearson correlation test was conducted to examine the relationships between user enjoyment and posttest scores on knowledge, attitude, self-efficacy, and intention to start a home garden.

Ethical Considerations

The institutional bioethics review board of the Centro de Investigación Científica y de Educación Superior de Ensenada approved all study procedures (BIOETICA_HUM_2023_03). Participants who expressed interest in joining the study provided written informed consent. The study ensured that all collected data were anonymized or de-identified to protect personal information, implementing strict protective measures for any data that could not be fully anonymized. Participation in the study was voluntary and uncompensated.

Results

Participant Characteristics

Of the 180 students and teachers approached, 50 (27.8%) agreed to participate in the study. The participants had an average age of 21.5 (SD 6.8) years, with 66% (33/50) being male and 34% (17/50) being female. Among the participants, the EG consisted of 25 individuals with an average age of 20.2 (SD 0.7) years, comprising 11 (44%) female and 14 (56%) male individuals. The CG also consisted of 25 participants with an average age of 22.7 (SD 9.5) years, including 6 (24%) female and 19 (76%) male individuals.

Knowledge of Home Gardening

The knowledge of participants (Table 2) in the EG significantly increased from T_0 to T_1 (mean difference 3.2, SD 0.18; t_{24}=4.26; *P*<.001). Similarly, the CG showed a significant increase in knowledge (mean difference 5, SD 0.3; t_{24}=6.78; *P*<.001). Comparing the differences in knowledge increases between groups from T_0 to T_1, no statistically significant differences were found (t_{24}=–1.71; *P*=.09). However, the CG had a slightly higher mean increase in knowledge (mean 5, SD 3.68) compared to the EG (mean 3.2, SD 3.75). Analyzing the results based on question difficulty, the EG showed a significant knowledge increase for easy (*P*=.02), medium (*P*=.03) and hard (*P*<.001) questions. Similarly, the CG showed a significant knowledge increase for easy (*P*<.001) medium (*P*=.001) and hard (*P*<.001) questions. There were no significant differences between the groups in the knowledge increase for the questions of easy (t_{24}=–0.68; *P*=.09) and medium (t_{24}=–0.73; *P*=.09) difficulty. However, a significant difference was observed for hard questions (t_{24}=0.64; *P*=.005), with the CG achieving a higher mean score (mean 5.76, SD 1.27) than the EG (mean 4.76, SD 1.39).

Attitude Toward Home Gardening

The attitude toward home gardening of participants (Table 3) in the EG significantly increased from T_0 to T_1 (mean difference 0.8, SD –0.01; z_{24}=2.98; *P*=.003). When analyzing the results by question, significant differences (*P*<.05) were found for all items. In contrast, there was no significant difference in the attitude toward home gardening of the CG from T_0 to T_1 (mean difference –0.05, SD –0.09; z_{24}=−0.54; *P*=.59) including individual questions. A significant difference was observed in attitude toward home gardening increase between groups from T_0 to T_1 (z_{24}=2.73; *P*=.006). Furthermore, the EG exhibited a higher mean increase in attitude toward home gardening (mean 0.8, SD 1.21) than the CG (mean –0.05, SD 1.30).

Self-Efficacy in Home Gardening

The self-efficacy in home gardening of participants (Table 4) in the EG significantly increased from T_0 to T_1 (mean difference 0.75, SD –0.01; t_{24}=2.6; *P*=.02). When analyzing the results by question, all items showed significant differences (*P*<.05). In contrast, the CG did not show a significant increase in self-efficacy in home gardening from T_0 to T_1 (mean difference –0.09, SD –0.17; t_{24}=–0.36; *P*=.72) or in individual questions. Comparing the differences in self-efficacy in home gardening increase between the 2 groups revealed a significant difference (t_{24}=2.21; *P*=.03). Furthermore, the EG exhibited a higher mean increase in self-efficacy in home gardening (mean 0.75, SD 1.45) than the CG (mean –0.09, SD 1.25).

Intention to Start a Home Garden

The intention to start a home garden of participants (Table 5) in the EG significantly increased from T_0 to T_1 (mean difference 2.02, SD 0; z_{24}=4.15; *P*<.001). When analyzing the results by question, all items showed significant differences (*P*<.05). In contrast, the CG did not show a significant increase in intention to start a home garden from T_0 to T_1 (mean difference –0.18, SD 1.73; t_{24}=–0.64; *P*=.53) or in individual questions. Comparing the differences in intention to start a home garden increase between the 2 groups revealed a significant difference (t_{24}=–5.33; *P*<.001). Furthermore, the EG exhibited a higher mean increase in intention to start a home garden (mean 2.01, SD 1.46) than the CG (mean –0.19, SD 1.46).

Table 5. Results for intention to start a home garden.

Question	CG[a]			EG[b]			Intergroups, *P* value[c]

User Enjoyment

Results showed (Table 6) a significant difference between the participants' answers and the neutral value in all categories: concentration (z_{24}=4.11; *P*<.001; Cronbach α=0.90), goal clarity (z_{24}=4.15; *P*<.001; Cronbach α=0.97), feedback (z_{24}=3.92; *P*<.001; Cronbach α=0.96), challenge (z_{24}=4.03; *P*<.001; Cronbach α=0.93), autonomy (z_{24}=3.89; *P*<.001; Cronbach α=0.89), immersion (z_{24}=3.83; *P*<.001; Cronbach α=0.93), social interaction (z_{24}=3.82; *P*<.001; Cronbach α=0.93), and knowledge improvement (z_{24}=3.92; *P*<.001; Cronbach α=0.96). All categories exhibited a Cronbach α of >0.70, which indicates a high internal consistency in the questionnaire [57]. These results state that users positively evaluated the video game in all categories.

Table 6. Results for user enjoyment.

Measure	Questions, N	T_1[a] score, mean (SD)	Neutral value	*P* value[b]	Range	Cronbach α
Concentration	6	4.45 (0.82)	3	<.001	1.67-5	0.90
Goal clarity	6	6.77 (0.81)	3	<.001	1-5	0.97
Feedback	5	4.60 (0.80)	3	<.001	1-5	0.96
Challenge	6	4.52 (0.79)	3	<.001	1.67-5	0.93
Autonomy	3	4.48 (0.84)	3	<.001	1-5	0.89
Immersion	7	4.34 (0.90)	3	<.001	1-5	0.93
Social interaction	6	4.26 (0.91)	3	<.001	1-5	0.93
Knowledge improvement	5	4.61 (0.81)	3	<.001	1-5	0.96

[a]T_1: after the intervention.
[b]*P*<.05 was considered statistically significant.

Relationship Between User Enjoyment and Efficacy Outcomes

Results showed (Table 7) no statically significant relationship between user enjoyment scores and posttest knowledge (EGameFlow scale: r_{23}=0.26; *P*=.20) and intention (EGameFlow scale: r_{23}=0.06; *P*=.77) scores. In addition, the results showed a positive statically significant relationship between user enjoyment scores and posttest attitude (EGameFlow scale: r_{23}=0.72; *P*<.001) and self-efficacy (EGameFlow scale: r_{23}=0.67; *P*<.001) scores.

Table 7. Correlations of user enjoyment scores with posttest efficacy results.

Category	*r*	*P* value[a] (bilateral)
Player enjoyment and knowledge	0.26	.20
Player enjoyment and attitude	0.72	<.001
Player enjoyment and self-efficacy	0.67	<.001
Player enjoyment and intention	0.06	.77

[a]$P<.05$ was considered statistically significant.

Hypothesis Evaluation

On the basis of the aforementioned results, in this subsection, we summarize the validation of each hypothesis using appropriate statistical methods. In addition, Table 8 summarizes the statistical significance, indicating whether each hypothesis was confirmed based on these results.

Table 8. Summary of hypothesis evaluation.

Hypothesis	Statistical analysis results	*P* value	Hypothesis confirmed?
1A	$t_{24}=4.26$	<.001	Yes
1B	$z_{24}=2.98$	.003	Yes
1C	$t_{24}=2.6$	.02	Yes
1D	$t_{24}=2.21$	.03	Yes
2A	$t_{24}=–1.71$	.09	No
2B	$z_{24}=2.73$	.006	Yes
2C	$t_{24}=2.21$	.03	Yes
2D	$t_{24}=–5.33$	<.001	Yes
3A	$r_{23}=0.26$	.20	No
3B	$r_{23}=0.72$	<.001	Yes
3C	$r_{23}=0.67$	<.001	Yes
3D	$r_{23}=0.06$	.77	No

Discussion

Principal Findings

Overview

The findings of this study support the effectiveness of Farmily in enhancing knowledge of home gardening, promoting a positive attitude toward home gardening, increasing self-efficacy in home gardening, and fostering the intention to start a home garden among novice individuals aged 20 to 50 years. In addition, Farmily demonstrated comparable effectiveness in knowledge transfer and a more significant impact on the other variables than a home gardening workshop facilitated by an expert in agriculture. Finally, Farmily yielded favorable results in user enjoyment, and we identified a significant positive relationship between user enjoyment and attitudes and self-efficacy and no relationship with knowledge and intention. The following sections comprehensively analyze each hypothesis, presenting the corresponding findings in detail.

Knowledge of Home Gardening

The EG demonstrated improved knowledge of home gardening after the treatment. Thus, our data support hypothesis 1A (confirmed). These results are consistent with those of previous studies on the effectiveness of video games in agricultural education [36-38,58]. Similarly, the CG also showed improved knowledge after the treatment. Regarding hypothesis 2A (rejected), there were no significant differences between the groups regarding the increase in knowledge overall and for easy and medium questions. However, a significant difference was found for difficult questions. These findings suggest that persuasive video games can be comparably effective to expert-led workshops in certain aspects but they may have limitations in more complex scenarios. It is important to acknowledge that workshops offer the advantage of direct interaction with experts, providing specific answers and in-depth knowledge. On the other hand, video games are constrained by the information provided within them. However, our video game demonstrated its potential effectiveness. Simulation-based experimentation has been successful in various fields, enabling competence development through trial-and-error experiences [59]. The discovery learning theory supports that knowledge is constructed through an iterative discovery process facilitated by educators [60]. Our results indicate that a serious persuasive video game can be valuable for reinforcing knowledge and complementing traditional educational techniques, particularly in noncomplex knowledge activities.

Attitude Toward Home Gardening

Regarding hypothesis 1B (confirmed), the participants in the EG demonstrated a significant improvement in their attitude toward home gardens. These results are consistent with findings of studies such as that on MahindiMaster [41], supporting our results. In contrast, the CG showed a nonsignificant decrease in attitude. Regarding hypothesis 2B (confirmed), the EG exhibited a higher mean increase in attitude than the CG. The divergence in results can be attributed to the unique firsthand experimentation experience provided by the simulation environment in Farmily. Actively engaging in virtual home gardening activities likely influenced participants' perception of the garden's interest, importance, and enjoyment, leading to a positive attitude toward real-life gardening. This finding aligns with the literature suggesting that providing new information can change attitudes toward an object [61]. The persuasive messages embedded in the video game may have also contributed to the favorable attitude change as persuasive technologies have been shown to influence attitudes and behaviors effectively [62,63].

Self-Efficacy in Home Gardening

Regarding hypothesis 1C (confirmed), participants in the EG demonstrated a significant improvement in their self-efficacy. These results are consistent with those of previous studies reporting positive effects on self-efficacy after intervention in video games [64]. Similarly, video games such as "Game of Piglets" [40] have increased players' self-efficacy in agriculture-related topics following interventions, supporting our expectations for our video game. In contrast, the CG showed a nonsignificant decrease. Regarding hypothesis 2C (accepted), the EG exhibited a higher mean increase in self-efficacy than the CG. As described by Bandura [53], self-efficacy is an integral part of the self-system, encompassing a person's attitude, ability, and cognitive abilities. According to Bandura [44], individuals develop self-efficacy beliefs through previous performance outcomes, vicarious experiences, social persuasion, and emotional and physiological states. The direct experience of EG users with the simulation of the home garden had a profound impact on their perception of their capabilities. The feedback and recommendation systems within the video game allowed players to analyze their previous performances, reinforcing their sense of competence. In addition, the recognition received when completing a level served as a form of social persuasion, offering congratulations and encouragement. In contrast, the workshop provided only vicarious experiences, lacking the opportunity for hands-on experimentation, which may explain its limited impact on self-efficacy.

Intention to Start a Home Garden

Regarding hypothesis 1D (confirmed), participants in the EG showed a significant improvement in their intention. These results were expected and explained through the Unified Theory of Behavior proposed by Jaccard et al [65], which states that 2 key factors influencing an individual's intention to engage in a behavior are their attitude toward the behavior and their self-efficacy. In the case of the EG, attitude and self-efficacy showed significant increases, which directly contributed to enhancing their intention. Conversely, the CG did not exhibit significant differences in these variables, resulting in no notable change in intention. Regarding hypothesis 2D (confirmed), the EG exhibited a higher mean increase in intention than the CG. These results can also be explained by the UTAUT proposed by Venkatesh et al [55]. According to this theory, participants in the EG may have realized that the perceived complexity and effort associated with engaging in a home garden were lower than initially expected (expectation of effort). Moreover, their direct experimentation with the video game enabled them to discover their capabilities and potential for performing well in a real garden (performance expectancy). Furthermore, it is plausible that the video game impacted other variables such as social norms and emotions by including persuasive messages. However, it is important to note that no specific data or evidence regarding these phenomena were collected in the study. We did not identify previous studies on the intention to start a home garden, but given that a change in intention leads to a small to medium change in behavior [66], several studies that achieved a positive behavior change [21] may have successfully influenced intention. However, there is a need for more data to corroborate that assumption.

User Enjoyment

Farmily received highly positive ratings across various user enjoyment categories, including concentration, clarity of goals, feedback, challenge, autonomy, immersion, social interaction, and knowledge increase. Participants expressed satisfaction with the gameplay, level of challenge, clarity of objectives, and overall video game mechanics. The success of Farmily in providing positive user enjoyment can be attributed to the mixed methodology used during its design. The iterative development process and continuous feedback from home garden experts ensured the creation of a video game with a robust knowledge base. The interdisciplinary composition of the team, including a video game designer, an interaction expert, and an education expert, played a significant role in crafting clear, immersive, and enjoyable video game mechanics, pedagogical techniques, and interactive elements within the final product.

Relationship Between User Enjoyment and Efficacy Outcomes

Regarding hypotheses 3B (confirmed) and 3C (confirmed), the findings revealed a positive statistical relationship between user enjoyment scores and attitude and self-efficacy posttest scores. These results suggest that players who enjoy the game also have a positive attitude and can master the game. These results are consistent with those of previous studies on the relationship between enjoyment and attitudes (eg, environmental sustainability attitude [67] and attitude toward real-life refugees [68]) and the relationship between enjoyment and self-efficacy (eg, genocide awareness [69] and drinking refusal self-efficacy [70]). In addition, regarding hypotheses 3A (rejected) and 3D (rejected), there was no statistically significant correlation between user enjoyment scores and posttest scores measuring both knowledge and intention, suggesting that enjoyment does not appear to be associated with knowledge acquisition or the propensity to engage in home gardening. These results are particularly surprising given the contrast with previous research examining the connection between enjoyment and learning outcomes in serious gaming contexts, as evidenced by studies investigating food knowledge [71] or mathematical proficiency [72]. However, it is worth noting that some studies have also failed to establish a relationship between enjoyment and learning [73]. Furthermore, these findings diverge from those of studies exploring the relationship with behavioral intentions, such as those examining intentions related to reducing alcohol consumption [70].

Limitations and Future Work

This study's findings should be cautiously interpreted due to the small sample size (n=50). Future research would benefit from a larger sample to enhance statistical reliability. Despite this limitation, the results provide valuable insights into video games as a tool for promoting home gardening. The participant pool, composed solely of students and teachers, may not fully represent the broader adult population aged 20 to 50 years. Moreover, participants reported high previous experience with video games and technology, which may not represent the general population. The short treatment and evaluation period (90 minutes) only captures immediate effects, not longer-term impacts. In addition, the knowledge questionnaire was developed specifically for this study in collaboration with a home garden expert, potentially influencing the results. Finally, leveraging a serious video game for promoting home gardening in areas of a low socioeconomic status can empower individuals with practical skills, foster sustainability, and build community resilience. However, it must be implemented with careful consideration of literacy rates, technological access, cultural relevance, and ongoing engagement strategies to maximize its impact. An enhanced version of Farmily is planned, incorporating elements such as climate simulation, disease management, and crop rotation and association. Future investigations are underway to use a more diverse sample and extend follow-up periods, thereby enabling comprehensive analysis. Furthermore, these efforts seek to deepen our understanding of the intricate relationship between enjoyment and persuasive outcomes within gaming environments.

Conclusions

Farmily, a 3D simulation single-player serious persuasive video game, was developed to educate and promote home gardening in novice individuals. The evaluation study demonstrated Farmily's effectiveness in improving participants' knowledge, attitude, self-efficacy, and intention to start their home gardens. Farmily demonstrated similar effectiveness in knowledge transfer to that of a traditional promotion workshop and had a more significant impact on other variables. The findings highlight Farmily's potential to empower individuals and promote sustainable practices by teaching the required home gardening knowledge and persuading them to start a real home garden. Furthermore, player enjoyment substantially correlates with user attitudes and self-efficacy, yet no discernible association was observed between enjoyment and knowledge and intention. Future research could expand on the impact of Farmily by conducting studies with more extensive and diverse samples over an extended time frame, including a follow-up period. These studies would allow for a deeper understanding of the medium- and long-term effects of Farmily and the sustainability of its impact over time. Moreover, additional research endeavors have the potential to advance our knowledge of the intricate interplay between enjoyment and persuasive outcomes in gaming contexts.

Acknowledgments

The authors thank the National Council of Science and Technology of Mexico for their support (scholarship 806581 awarded to the first author) and the teachers and students who participated in this study. They appreciate the support and cooperation of the authorities at the Instituto Tecnológico de Ciudad Guzmán. Special thanks to engineers Enriqueta Sánchez Bernal, Teresa Licea González, and Dr Elia Cruz Crespo for their valuable contributions to designing and reviewing Farmily's agricultural content. The authors also acknowledge Enriqueta Sánchez Bernal for conducting the home gardening workshop during the evaluation.

Authors' Contributions

All authors contributed to the study's conception and design. CAGAC, IEEC, and RMMN performed material preparation and data collection and analysis. The first draft of the manuscript was written by CAGAC, and all authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: High-intensity interval training (HIIT) has become a popular exercise strategy in modern society, with the Tabata training method being the most popular. In the past, these training methods were mostly done without equipment, but incorporating exergaming into the training may provide a new option for muscle training.

Objectives: The aim of this study was to explore the differences in upper limb muscle activation using an HIIT program combined with exergaming.

Methods: A total of 15 healthy male participants were recruited for the study, and the differences in muscle activation were compared between push-ups and exergaming (Nintendo Switch Ring Fit Adventure with the Ring-Con accessory) during HIIT. Prior to the tests, participants underwent pretests, including maximal voluntary contractions of various muscle groups, maximal push-up tests, and maximal movement tests using the exergaming device. The push-up and exergaming tests were conducted on separate days to avoid interference, with a warm-up period of 5 minutes on a treadmill before testing. Muscle activation in the lateral and anterior portions of the deltoid muscle, the sternal and clavicular heads of the pectoralis major muscle, and the latissimus dorsi muscle were measured during the maximal voluntary contractions and single-round tests for each exercise mode. A repeated measures ANOVA was used to assess the variations in muscle activation observed across the 2 distinct modes of exercise, specifically push-ups and exergaming.

Results: In exergaming, the number of repetitions for push-ups was significantly fewer than for single-site exercises across both exhaustive (mean 23.13, SD 6.36 vs mean 55.67, SD 17.83; *P*=.001; effect size [ES]: 2.43) and single-round (mean 21.93, SD 7.67 vs mean 92.40, SD 20.47; *P*=.001; ES: 4.56) training. Heart rate differences were not significant (all *P*>.05), yet exergaming led to better muscle activation in specific muscle groups, particularly the right anterior deltoid (mean 48.00%, SD 7.66% vs mean 32.84%, SD 10.27%; *P*=.001; ES: 1.67) and right pectoralis major (sternal head: mean 38.99%, SD 9.98% vs mean 26.90%, SD 12.97%; *P*=.001; ES: 1.04; clavicular head: mean 43.54%, SD 9.59% vs mean 30.09%, SD 11.59%; *P*=.002; ES: 1.26) during exhaustive training. In single-round training, similar patterns were observed with the anterior deltoid (mean 51.37%, SD 11.76% vs mean 35.47%, SD 12.72%; *P*=.002; ES: 1.30) and pectoralis major (sternal head: mean 53.27%, SD 10.79% vs mean 31.56%, SD 16.92%; *P*=.001; ES: 1.53; clavicular head: mean 53.75%, SD 13.01% vs mean 37.95%, SD 14.67%; *P*=.006; ES: 1.14). These results suggest that exergaming may be more effective for targeted muscle activation.

Conclusions: In conclusion, HIIT can increase muscle activation in the upper extremities and can be incorporated into exergaming strategies to provide a fun and engaging way to exercise.

Introduction

In recent years, motion-based video games have made substantial contributions to both medical education and sports training [1]. They have shown notable effects in the rehabilitation or training of upper limbs [2-4]. The enjoyment derived from gaming can enhance participants' motivation, and when combined with specific game design, it becomes one of the hot topics in research. Compared to longer-duration, moderate-intensity exercise, the strategy of high-intensity interval training (HIIT) [5] has become the mainstream exercise approach in modern society. The most popular approach is the Tabata training method, which involves performing 8 cycles of 20 seconds of all-out exercise, interspersed with 10 seconds of complete rest, for a total exercise time of 240 seconds [6]. Results have shown significant improvements in aerobic power [7], fat oxidation [8], and muscular endurance [9]. It can be observed that the HIIT strategy not only shortens exercise participation time but also has positive effects on the body. Tabata exercises, apart from running, also include various forms of bodyweight exercises, such as push-ups, squats, and burpees [10]. Among these, push-ups are the most used bodyweight exercise in Tabata training. In a study on muscle activation for strength training, Alizadeh et al [11] investigated the muscle activation patterns of push-ups and sit-ups, measuring the activation of the anterior and lateral portions of the deltoid muscle, as well as the sternal and clavicular heads of the pectoralis major muscle. The results showed variations in muscle activation levels despite the similarity in the exercises, highlighting differences in muscle engagement across different parts of the body. Another study by Putra et al [12] explored the muscle activation levels in the upper limbs during a boxing game while in standing and sitting positions in virtual reality gaming. The study found significant differences in the activation of the upper trapezius muscle during uppercut punches, whereas no differences were observed in straight and hook punches. Combining the findings of these 2 studies, it is evident that different exercises lead to varying levels of muscle activation in different muscle groups.

Push-ups, historically used to assess upper body strength, are frequently incorporated into HIIT sessions. This exercise primarily targets the deltoid, pectoralis major, and latissimus dorsi muscles. Similarly, virtual reality gaming offers training modes specifically designed to target these muscle groups. In summary, the research highlights the diverse muscle activation patterns associated with different exercises. Push-ups, a fundamental bodyweight exercise, have been traditionally used to assess upper body strength and are a common component of HIIT workouts, effectively engaging the deltoid, pectoralis major, and latissimus dorsi muscles. Additionally, virtual reality gaming provides tailored training modes focusing on these specific muscle groups. For individuals engaged in recreational physical activities, these conventional exercise methods might be perceived as monotonous due to their limited variation, potentially leading to reduced adherence to training. This lack of variety could negatively impact exercise adherence, as the "lack of enjoyment" is frequently cited as a common barrier to regular physical activity [13].

In studies on the application of HIIT in strength training, the focus has been on investigating the rest intervals between exercises [14] and movement speed [15]. Tomoo et al [14] examined the effects of long and short rest intervals between sets and found that shorter rest intervals led to higher muscle activation levels at the same exercise intensity. In contrast, Dora et al [15] found that faster movement speed resulted in higher muscle activation levels. Taken together, these studies suggest that shorter rest intervals and faster movement speed lead to greater muscle activation. Previous literature has also shown that shorter rest intervals can improve muscle adaptations during resistance training [16,17]. However, in upper body exercise design, push-ups are commonly included as one of the training movements and are frequently used to assess upper body muscle strength and endurance [18].

Exergaming have been used for exercise training for many years and have contributed to improving exercise participation [19]. Related exergaming devices includes Xbox 360, Nintendo Wii, Nintendo Switch, and Sony PlayStation 2. Through exergaming, aerobic capacity, agility, muscle strength, muscle endurance, and coordination can be improved [20]. Regarding muscle strength training, Willaert et al [21] showed that muscle activation can be improved by more than 40%. Although the level of activation is relatively low, this study aims to design a training program with the combination of HIIT and body-sensing video games to enhance the quality and effectiveness of the training. There are relatively few studies on the use of HIIT for muscle strength training, and the level of muscle activation using exergaming combined with HIIT has not been clarified. The aim of this study was to explore the differences in upper limb muscle activation using an HIIT program combined with exergaming.

Methods

Study Participants

In this study, we recruited 15 healthy male participants. They had an average age of 24.4 (SD 10.4) years, stood at an average height of 174 cm with a minimal variance of 0.05 cm, and weighed an average of 71.9 (SD 13) kg. Their BMI averaged at 23.5 (SD 3.57) kg/m^2. All participants maintained a regular exercise routine, engaging in physical activity 3 times per week over the past year, and had experience in performing push-ups correctly. They also completed the Physical Activity Readiness Questionnaire [22] and confirmed that they had no history of upper or lower limb skeletal muscle injury or major injury. Participants were instructed to avoid vigorous activity and the intake of caffeine or supplements that enhance muscle performance for 24 hours prior to the experiment. Before the study began, all participants provided their personal information and medical history and filled out the health questionnaires and informed consent form. Additionally, the data were proofread to ensure accuracy and readability.

Ethical Considerations

The human research ethics committee of the local university approved this study, which was also approved by the human research ethics committee of the National Cheng Kung

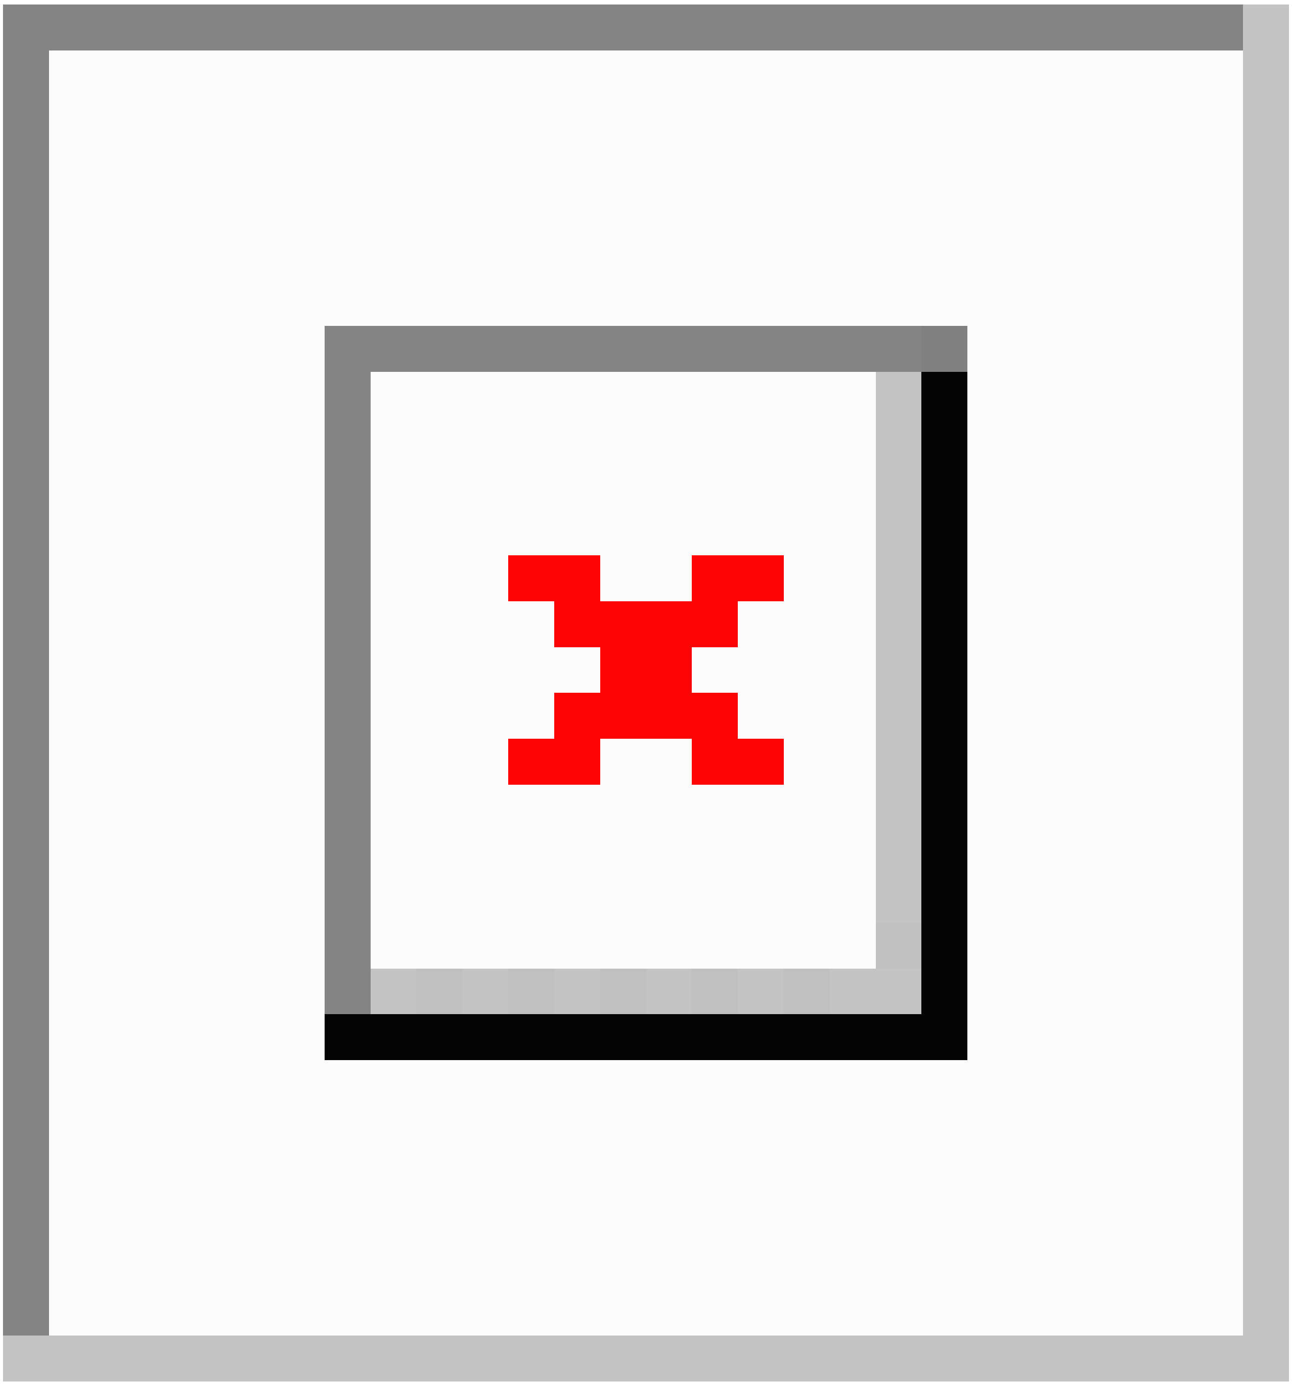
University, Taiwan (approval NCKU HREC-E-112-419-2). Users volunteered for this study and agreed to participate by signing an informed consent form. The research ensures the issues of privacy and confidentiality by assigning participants with numerical identifiers during the experiment to safeguard the confidentiality of their personal information. In terms of compensation, participants were volunteers and there was no remuneration involved.

Experimental Design

Overview

This study used a randomized, crossover, and repeated measures experimental design to compare the differences in muscle activation between push-up exercise and a Nintendo Switch Ring Fit Adventure exercise. Prior to the tests, participants underwent pretests, which included maximal voluntary contractions (MVCs) for each muscle group, maximal push-up tests, and maximal exercise tests for each part of the Nintendo Switch Ring Fit Adventure exercise. The 2 types of tests were conducted with a minimum interval of 3 days to avoid interference. Prior to each test, a 5-minute warm-up on the treadmill at a speed of 2 m/s was recommended. During the tests, muscle activation in various muscle groups was observed and measured, including the lateral and anterior portions of the deltoid muscle, the sternal and clavicular heads of the pectoralis major muscle, and the latissimus dorsi muscle, which were referenced and modified from previous studies by van den Tillaar [23], Alizadeh et al [11], and Maeo et al [24] (Figure 1). The aim was to explore the differences in upper limb muscle activation using an HIIT program combined with exergaming.

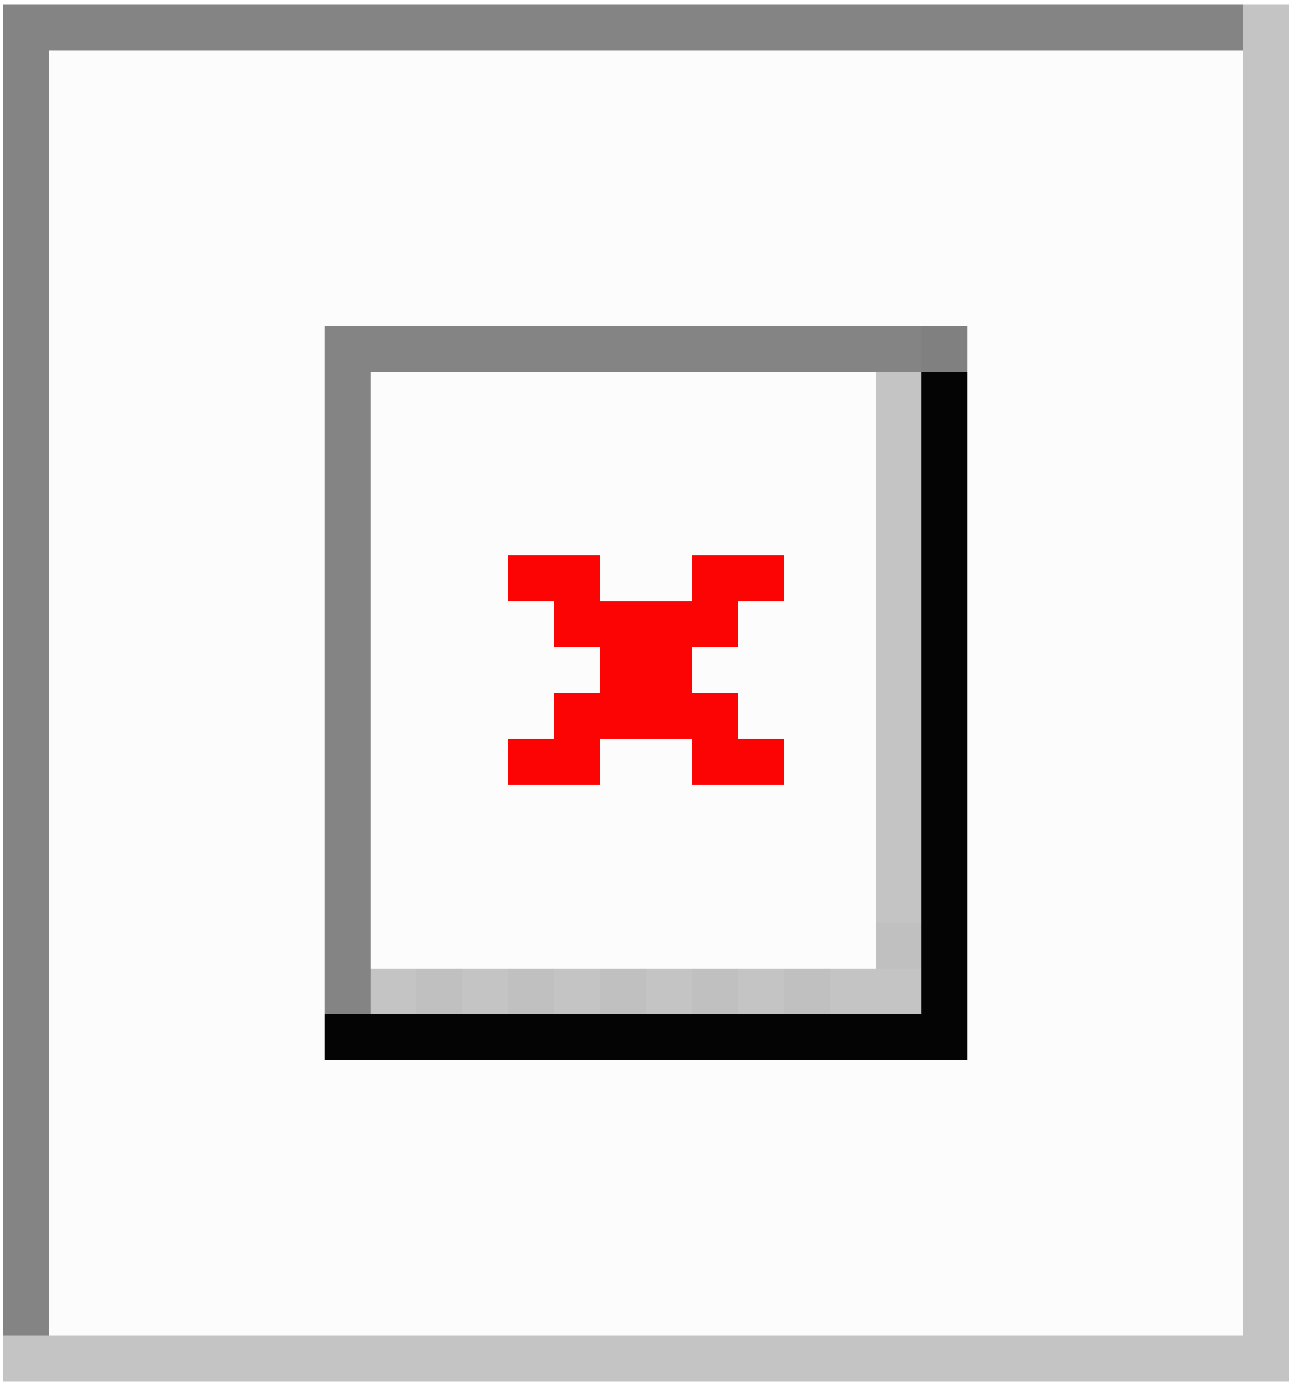
Figure 1. Experimental procedure diagram.



Exergaming

The exergaming selected for this study was Nintendo Switch Ring Fit Adventure, which combines exercise, adventure, and entertainment, allowing players to enjoy both physical workouts and gaming fun simultaneously. The game features an intuitive and user-friendly interface, suitable for players of all ages. It comes with a specialized fitness ring device (Ring-Con), an intelligent accessory that connects to the Nintendo Switch console. Through this ring, players can engage in various physical activities such as weightlifting, yoga, and aerobic exercises. The fitness ring sensor accurately captures players' movements and incorporates them into the gameplay. The game content involves unlocking levels and participating in fitness competitions through real-life physical movements. It offers a variety of fitness activities, each targeting different muscle groups, while also providing enjoyable gaming challenges. The trained muscle groups were the pectoralis major, deltoid, and latissimus dorsi muscles. The testing consisted of 2 modes: (1) maximum repetition test and (2) single-round test. The maximum repetition test was conducted using the extreme challenge mode. Participants were instructed to follow the game's pace of 60 beats per minute as closely as possible and maintain proper posture during each muscle group's testing to avoid compensation from other muscles. The single-round test was conducted using the challenge mode. Participants were instructed to perform repetitive actions as quickly as possible for 20 seconds (Figure 2).

Figure 2. Exercise training and exergaming model: (A) pectoralis major, (B) deltoid, and (C) latissimus dorsi.



Push-Up Tests

The push-up tests included 2 types of tests: (1) maximum repetition test and (2) single-round test. The maximum repetition test was based on the testing method described by Eckel et al [25]. Participants were guided to execute the test while in sync with a metronome set at 60 beats per minute, ensuring each movement, 1 second downward and 1 second upward, matched the rhythm precisely. This cadence was chosen to align with the pace of exercises conducted in the Nintendo Switch Ring Fit Adventure exercise, facilitating a consistent and controlled environment for comparison. During the test, the distance between the hands at the sternal notch level was measured and must be the same as the distance used in the single-round test. The elbow must be bent at 90° and the elbow must be fully extended when straightened. The single-round test was designed to match the duration of a single round of the Nintendo Switch Ring Fit Adventure exercise and involved performing the maximum number of squats possible within 20 seconds.

Heart Rate Tests

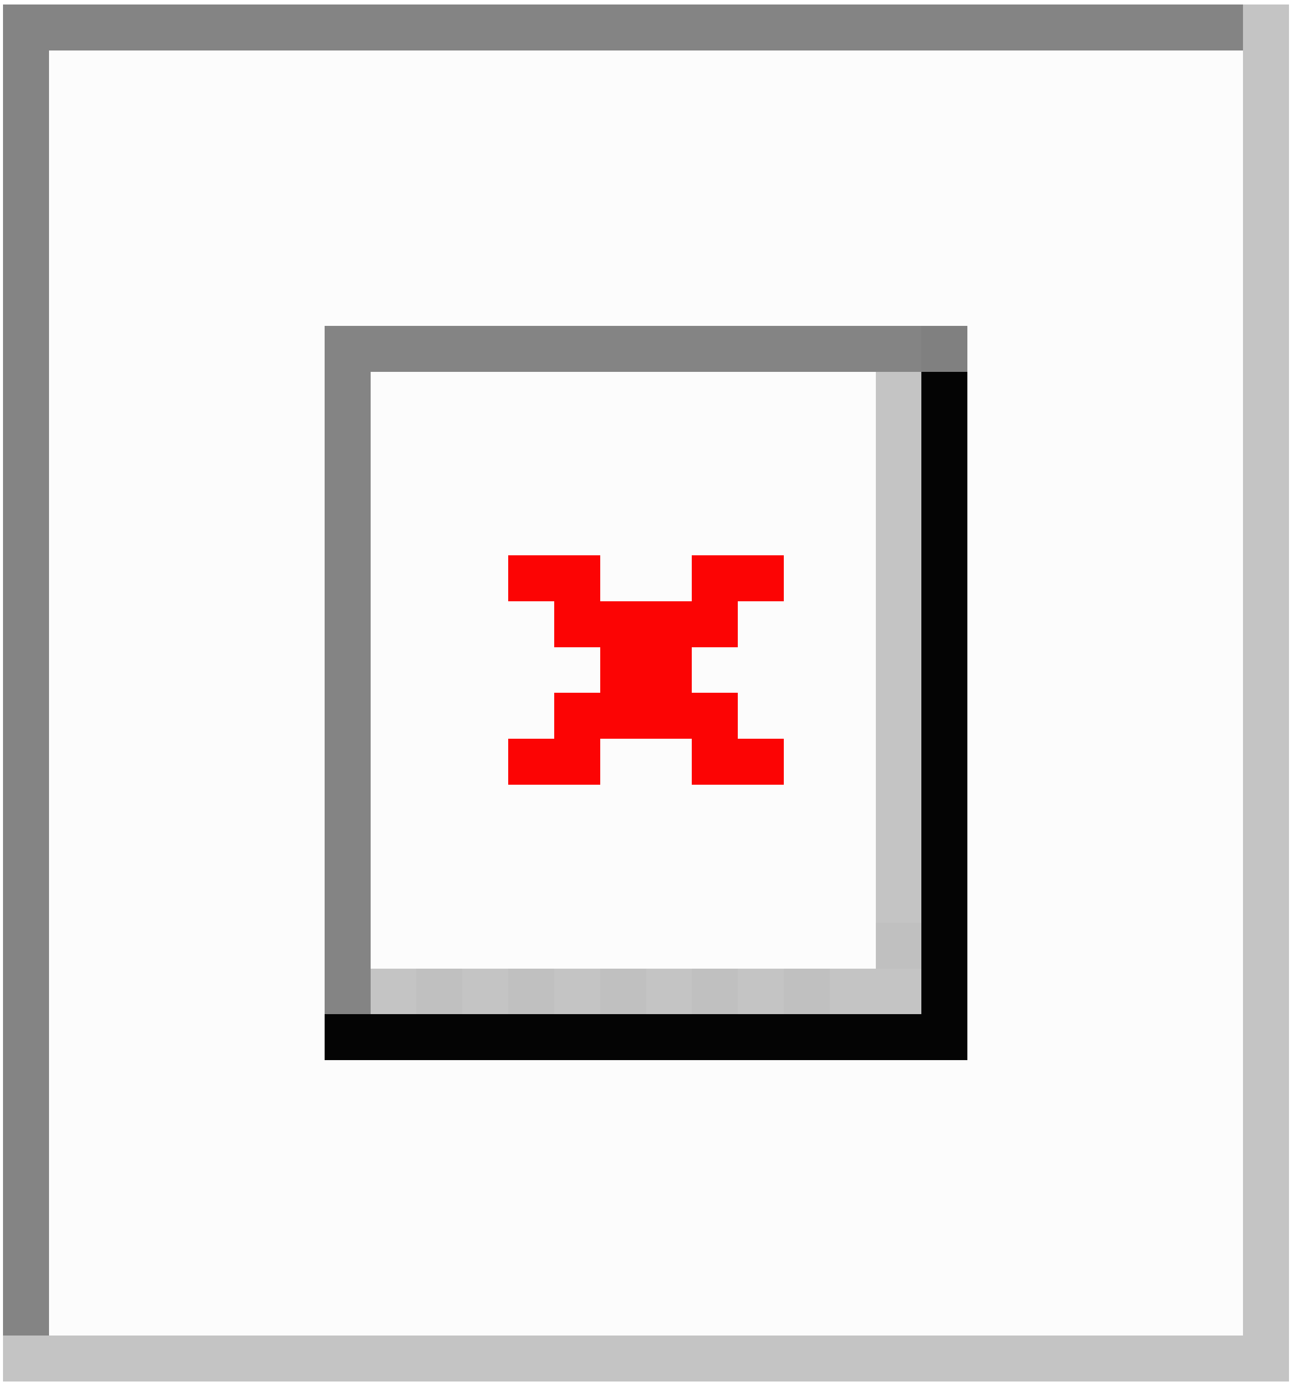
Heart rate measurements were taken using the iHeart heart rate sensor (Hexin) during push-up tests and exergaming sessions. The heart rate sensor was worn directly below the sternum and in direct contact with the skin, ensuring a comfortable fit that remained secure without slipping, even during exercise. After being fitted, the sensor was connected to the Polar Beat app (Polar Electro) for monitoring and recording purposes.

Electromyography

MVC Testing

In MVC testing, each muscle group underwent an isometric MVC prior to the test. After a running warm-up and a 3-minute rest period, the MVC test was performed according to the movements described by Konrad [26]. The test consisted of 3 attempts, each lasting 5 seconds with 1-minute rest intervals in between, and the participant was encouraged to exert maximum effort during each attempt. If the peak MVC values differed by more than 5%, additional testing was performed. The test procedures for each muscle group were as follows. (1) Deltoid: the participants were seated with their backs supported, and their arms were abducted to a position where they formed a 90° angle with the trunk, maintaining a horizontal plane. A rope, fixed to the arm, was then pulled upward to measure the force exerted. (2) Pectoralis major: the participants performed the test in a lying position with the elbows extended and flexed at 90°, holding onto a long bar with a fixed rope attached to each side of the bar and pulling upward as hard as possible to measure the force exerted. (3) Latissimus dorsi: the participants performed the test in a seated position, simulating the movement of a pull-up. The axis joint was flexed and abducted at 90°, and the rope was pulled downward the measure the force exerted, as shown in Figure 3. After the MVC testing, electromyography (EMG) electrodes were placed on the skin over the belly of the tested muscles for subsequent signal recording and analysis.

Figure 3. (A) Standardized illustrations for the MVC action of each muscle. (B) MVC sensor placement for each muscle. MVC: maximal voluntary contraction.



EMG Measurement and Analysis

The Trigno TM wireless foundation system (Delsys-EMGworks) was used for data collection in this study, measuring the anterior and lateral portions of the deltoid muscle, the sternal and clavicular heads of the pectoralis major muscle, and the latissimus dorsi muscle [11,23,24]. The system was configured with a sampling rate set at 2000 Hz per channel, tailored to the desired sample rate specifications. For the processing of EMG data, we used the EMGwork analysis software, which included steps of filtering and smoothing the EMG signals to ensure clarity and accuracy. The filtering process used a band-pass filter with a low-frequency cutoff at 20 Hz and a high-frequency cutoff at 500 Hz. Following this, the rectified EMG signals underwent further refinement using the root mean square method, which facilitated a detailed analysis of the signal's magnitude. During the MVC test, we determined the highest EMG amplitude recorded for each muscle group, referred to as EMGmax. The data processing method in exergaming was the same as the above, and the degree of muscle activation was calculated based on the values obtained from the standardized action test, expressed as a percentage of EMGmax.

Statistical Analysis

Data processing and analysis were performed using SPSS for Windows (version 20.0; IBM Corp). The data were presented as mean and SD. To investigate the variance in motion and heart rate across different movements derived from the 2 exercise models—strength endurance and single round—we used a repeated measures ANOVA. Furthermore, to assess the discrepancies in muscle activation elicited by the 2 distinct types of exercises, namely push-ups and exergaming, a paired-samples 2-tailed *t* test was used. Cohen *d* for effect size (ES) was calculated by the G*Power 3.1 software program (Heinrich-Heine-Universität), where the ESs of 0.2, 0.5, and 0.8 were considered small, medium, and large, respectively. Statistical significance was set as *P*<.05.

Results

Study Participants

For this study, a total of 15 male participants from the community were recruited. These participants were generally in good health. However, finding healthy female participants capable of performing push-ups was challenging due to their limited availability. Therefore, this study predominantly concentrated on male participants.

Comparing Strength, Performance, and Heart Rate: Push-Ups Versus Exergaming

The results showed that regardless of the exhaustive or single-round mode, the number of single-site repetitions in exergaming was significantly higher than that of push-ups (exhaustive: deltoid, mean 55.67, SD17.83; pectoralis major, mean 52.53, SD 13.61; and latissimus dorsi, mean 82.30, SD 20.82 vs push-up, 23.13, SD 6.36; *P*=.001; ES: 2.43, 2.77, and 3.84, respectively; single round: deltoid, mean 92.40, SD 20.47; pectoralis major, mean 104.27, SD 13.48; and latissimus dorsi, mean 97.33, SD 16.77 vs push-ups mean 21.93, SD 7.67; *P*=.001; ES: 4.56, 7.51, and 5.78, respectively). However, there was no difference in heart rate between the 2 modes (all *P*>.05). Taken together, these results suggest that both whole-body push-ups and single-site exergaming training can increase heart rate and can be used to train cardiorespiratory fitness (Table 1).

Table . Comparison of strength endurance, single-round performance, and heart rate between push-ups and exergaming.

Model and motion		Repetitions, mean (SD)	*F* test (*df*)	*P* value	Heart rate (bpm[a]), mean (SD)	*F* test (*df*)	*P* value
Strength endurance test			50.83	.001		3.92	.07
	Push-up	23.13 (06.36)			101.27 (14.79)		
	Exergaming, deltoid	55.67 (17.83)			96.80 (21.29)		
	Exergaming, pectoralis major	52.53 (13.61)			98.06 (18.76)		
	Exergaming, latissimus dorsi	82.30 (20.82)			91.40 (14.23)		
Single-round performance (20 s)			143.27	.001		1.56	.21
	Push-up	21.93 (07.67)			100.33 (16.32)		
	Exergaming, deltoid	92.40 (20.47)			104.80 (14.63)		
	Exergaming, pectoralis major	104.27 (13.48)			93.67 (17.11)		
	Exergaming, latissimus dorsi	97.33 (16.77)			104.13 (16.05)		

[a]bpm: beats per minute.

Strength Endurance: Push-Ups Versus Exergaming

According to the statistical results, in the exhaustive mode, the activation levels of the right anterior deltoid (mean 48.00%, SD 7.66% vs mean 32.84%, SD 10.27%; *P*=.001; ES: 1.67), right pectoralis major—sternal head (mean 38.99%, SD 9.98% vs mean 26.90%, SD 12.97%; *P*=.001; ES: 1.04), and right pectoralis major—clavicular head (mean 43.54%, SD 9.59% vs mean 30.09%, SD 11.59%; *P*=.002; ES:1.26) were significantly greater in the exergaming group than in the push-up group. Thus, these results suggest that exergaming have a better training effect on specific muscle groups (Table 2).

Table . Comparison of muscle activation between traditional push-ups and exergaming in the strength endurance test.

Muscle	Push-up activation (%), mean (SD)	Exergaming activation (%), mean (SD)	*t* test (*df*)	*P* value
Anterior deltoid	32.84 (10.27)	48.00 (7.66)	−4.096	.001
Lateral deltoid	37.36 (13.79)	44.56 (8.82)	−1.737	.10
Pectoralis major, sternal head	26.90 (12.97)	38.99 (9.98)	−4.358	.001
Pectoralis major, clavicular head	30.09 (11.59)	43.54 (9.59)	−3.784	.002
Latissimus dorsi	35.43 (10.39)	34.01 (18.05)	0.329	.75

Single-Round Test: Push-Ups Versus Exergaming

Based on the statistical analysis, in the single-round mode, the activation levels of the right anterior deltoid (mean 51.37%, SD 11.76% vs mean 35.47%, SD 12.72%; *P*=.002; ES: 1.30), right lateral deltoid (mean 52.08%, SD 10.79% vs mean 43.86%, SD 10.48%; *P*=.046; ES: 0.77), right pectoralis major–sternum head (mean 53.27%, SD 10.79% vs mean 31.56%, SD 16.92%; *P*=.001; ES: 1.53), and right pectoralis major–clavicle head (mean 53.75%, SD 13.01% vs mean 37.95%, SD 14.67%; *P*=.006; ES: 1.14) were significantly greater in the exergaming group than the push-up group. These results suggest that the exergaming designed as an HIIT exercise targeting a specific muscle group resulted in significantly higher muscle activation compared to push-ups (Table 3).

Table . Comparison of muscle activation between traditional push-ups and exergaming in the single-round test.

Muscle	Push-up activation (%), mean (SD)	Exergaming activation (%), mean (SD)	*t* test (*df*)	*P* value
Anterior deltoid	35.47 (12.72)	51.37 (11.76)	−3.705	.002
Lateral deltoid	43.86 (10.48)	52.08 (10.79)	−2.190	.046
Pectoralis major, sternal head	31.56 (16.92)	53.27 (10.79)	−4.266	.001
Pectoralis major, clavicular head	37.95 (14.67)	53.75 (13.01)	−3.236	.006
Latissimus dorsi	41.49 (11.00)	38.17 (16.87)	0.645	.529

Discussion

Principal Findings

The results indicated that, in terms of the number of repetitions performed, both the strength endurance and single-round tests showed significantly higher execution rates for the exergaming training mode compared to push-ups. However, there were no significant differences in heart rate between the 2 modes. Regarding muscle activation, in the strength endurance test, exergaming exhibited significantly higher activation levels than push-ups in the anterior deltoid, pectoralis major–sternal head, and pectoralis major–clavicular head muscles. In the single-round test, exergaming demonstrated significantly higher activation levels than push-ups in the anterior deltoid, lateral deltoid, pectoralis major–sternal head, and pectoralis major–clavicular head muscles.

Heart Rate Response in Exergaming

Interestingly, the study did not observe significant differences in heart rate between the exergaming and push-up groups. This result contrasts with previous studies indicating that exergaming can lead to higher heart rates due to the immersive and stimulating nature of video game–based exercises [27,28]. The lack of significant heart rate differences could be attributed to the individual variability in cardiovascular responses and the adaptability of participants to the exergaming interface. HIIT has been shown to be an effective way to improve cardiovascular fitness and overall health [7]. Heart rate is an important factor in both exergaming and HIIT. Monitoring heart rate can help individuals ensure that they are working at an appropriate intensity level to achieve their fitness goals. In HIIT, heart rate can be used to guide the high-intensity intervals and rest periods to optimize the workout's effectiveness [29]. Overall, the use of exergaming and HIIT can provide a fun and effective way to improve physical fitness and health, with heart rate monitoring serving as an important tool to help individuals achieve their goals.

Another potential explanation for these results is that the use of exergaming may increase motivation and engagement in physical activity, leading to greater adherence to exercise programs [30]. This is especially important given the high rates of sedentary behavior and physical inactivity in modern society. Exergaming may provide a fun and enjoyable way to engage in physical activity, potentially leading to increased frequency and duration of exercise sessions [31,32]. This is particularly relevant for individuals who may struggle to engage in more traditional forms of exercise due to boredom, lack of motivation, or physical limitations.

EMG Response in Exergaming

This study investigated the effects of HIIT on muscle activation in the upper extremities. The results suggest that exergaming may be a more effective training method for upper extremity muscle activation compared to push-up exercises. The reason for this difference may be due to the specific muscles activated during exergaming, as the Nintendo Switch Ring-Con requires movements that engage the lateral and anterior parts of the deltoid muscle, pectoralis major muscle, and latissimus dorsi muscle. These findings suggest that exergaming can be a viable option for those looking to improve upper extremity muscle activation.

In interpreting the results, the study found that the exergaming training mode exhibited superior performance in terms of the number of repetitions compared to traditional push-ups, both in the strength endurance test and the single-round test. This finding aligns with previous research indicating the effectiveness of exergaming in enhancing endurance and strength capacities [33,34]. The higher execution rates in the exergaming group suggest that this interactive gaming approach offers a more engaging and motivating environment, encouraging participants to perform better and prolong their workout sessions compared to conventional push-ups. EMG can reflect the response of muscles during strength training. Alizadeh et al [11] investigated 2 common strength training exercises, push-ups and sit-ups, and measured muscle activation in the major muscle groups involved, such as the lateral and anterior portions of the deltoid and the sternal and clavicular heads of the pectoralis major. The results showed that even with the same exercise, different muscle groups were activated to varying degrees, indicating the importance of focusing on specific muscle group activation for muscle training. Compared to traditional strength training, there has been relatively little research on exergaming, but Putra et al [12] investigated the activation levels of upper limb muscles during a punching game while in standing and sitting positions. The results showed significant differences in the activation of the upper trapezius muscle during the execution of an uppercut punch, but not for straight or hook punches, indicating that the fixedness of the movements also affects the activation levels of different muscle groups in exergaming. Taken together, these studies suggest that different movements can affect muscle activation levels in different muscle groups. Therefore, choosing appropriate exercises and training modes is important for muscle strength training. Push-ups are a common exercise that mainly trains muscle groups, such as the deltoid, pectoralis major, and latissimus dorsi muscles, and are commonly used in HIIT. Training modes in exergaming are also available for these muscle groups, providing more diverse options for muscle training. Overall, these research results indicate the importance of understanding the relationship between movements and muscle groups.

Regarding muscle activation patterns, the exergaming group demonstrated significantly higher activation levels in specific muscles compared to traditional push-ups. In the strength endurance test, the anterior deltoid, pectoralis major–sternal head, and pectoralis major–clavicular head muscles exhibited increased activation during exergaming sessions. These findings corroborate with prior studies highlighting the targeted muscle engagement achieved through exergaming interventions [21]. The single-round test further showed elevated muscle activation in the anterior deltoid, lateral deltoid, pectoralis major–sternal head, and pectoralis major–clavicular head muscles during exergaming activities. This specific muscle activation pattern emphasizes the comprehensive nature of exergaming exercises, engaging various upper body muscles simultaneously [35]. One potential explanation for these results is that the Ring-Con is a novel type of resistance training that provides a more targeted and isolated workout for specific muscle groups [36]. This may allow individuals to activate and recruit more muscle fibers, leading to increased muscle activation compared to more traditional exercises such as push-ups. Additionally, the Ring-Con provides a unique form of resistance that can be adjusted to individual fitness levels, potentially allowing for greater customization and variety in workout routines [12].

Conclusions

In conclusion, this study demonstrated that exergaming may be a more effective strategy for upper extremity muscle activation compared to push-up exercises during HIIT. The specific movements required by the Nintendo Switch Ring-Con may activate the lateral and anterior parts of the deltoid muscle, pectoralis major muscle, and latissimus dorsi muscle more effectively. Furthermore, the HIIT protocol used in this study provides a time-efficient method for strength training. Incorporating exergaming into an HIIT program may provide a more engaging and effective strategy for improving upper extremity muscle activation. Further research is needed to investigate the long-term effects of exergaming on upper extremity muscle activation and strength.

Abstract

Background: Declines in physical and cognitive function are natural biological processes, leading to an increased risk of falls. Promising evidence suggests that combined physical-cognitive exercise has beneficial effects in improving both physical and cognitive health. Although moderate-to-high exercise intensity is commonly recommended, it might be impractical for older adults facing physical limitations or contraindications. Thus, low-intensity exercise is a viable option. The main barriers to engaging in exercise in older adults include transportation, time, motivation, and enjoyment. To overcome these challenges, a home-based, gamification-based training system may provide an effective approach to enhance exercise adherence.

Objective: This study aimed to develop and evaluate the usability of a low-intensity, gamification-based, interactive physical-cognitive exercise for older adults in a home-based setting.

Methods: The prototype of a game-based physical-cognitive exercise was created following the ADDIE model (analysis, design, development, implementation, and evaluation) and assessed for user experience in older adults. A total of 15 older adults engaged in the game-based physical-cognitive exercise at home for 60 minutes per day, 3 days per week, for 4 weeks. The usability of the game-based training system was evaluated using the system usability scale (SUS) after completion of a 4-week training program. As for satisfaction, the 8-item Physical Activity Enjoyment Scale (PACES) questionnaire was used to assess participants' enjoyment level after 1 week and 4 weeks of training. Descriptive statistics were used to illustrate the SUS score. A Wilcoxon signed-rank test was used to compare the PACES scores between the first week and the end of the 4-week period, with significance set at $P<.05$.

Results: As for experts' consensus, the game-based training consisted of 3 games: Ocean Diver, Road Runner, and Moving and Memorizing. The games had 3 levels of difficulty: beginner, intermediate, and advanced. A computer vision–based system was selected as the delivery platform for a home setting. The total SUS score for all participants was mean 87.22 (SD 5.76), indicating the user's perception of the usability of a system ranging from good to excellent. At the end of the 4-week training, the total PACES score was significantly greater than the first week, suggesting an improvement in enjoyment (first week: mean 44.93, SD 3.99 vs fourth week: mean 50.53, SD 4.70; P=.001).

Conclusions: The prototype of low-intensity, gamification-based, interactive physical-cognitive training was designed and developed using the ADDIE model, which included both experts and end users in the process. The findings showed that the exergame prototype was a usable and practical approach for a home-based setting, enhancing older adults' enjoyment and motivation. Further research is warranted to determine the effectiveness of such gamification-based training in promoting physical and cognitive functions.

Introduction

Aging is a natural biological process leading to a gradual decline in both physical and cognitive abilities. Physical decline in older adults, which contributes to their susceptibility to falls, includes intraindividual factors such as muscle weakness, delayed reaction time, impaired vision and proprioception, and impaired balance [1]. In addition to a decline in physical function, older adults may also experience problems in cognitive function, primarily involving executive function, attention, and processing speed, which are significant risk factors for falls [2]. Given that physical and cognitive impairments coexist in aging and are indicators of the risk of falls, it is essential to identify effective strategies to enhance both physical and cognitive functions for fall prevention.

It is well established that exercise serves as an effective strategy for fall prevention among older adults by ameliorating physiological fall risk factors such as muscle weakness and poor balance [3,4]. Accumulating evidence has demonstrated that exercise benefits not only physical function but also cognitive function. Given that cognitive impairment is an independent risk factor for falls, improving cognitive function through exercise may further contribute to fall risk reduction [5-7]. Among various types of exercise, combined physical-cognitive training (simultaneous training) has a profound effect on cognitive and physical health, reducing the risk of falls in older adults, and it is superior to single-component training [8,9]. Although moderate-to-high intensity exercise is widely recommended for reducing the risk of falls, its applicability may be limited for certain older adults with physical restrictions or contraindications. Currently, a growing body of evidence has suggested that low-intensity exercise has a positive effect on cognitive and physical performance in adults and older adults with and without pathologic conditions [10-13]. With this, a low-intensity exercise may be a promising alternative approach for fall prevention in older adults who experience physical limitations that prevent them from engaging in moderate-to-high intensity exercise.

With current technological advancements, gamification, which involves using game-based mechanics to motivate individual action and learning for a specific target, is increasingly used in health care services, especially for promoting exercise [14,15]. Among gamification-based exercises, combined physical-cognitive training has emerged through exergames that require individuals to move their bodies to interact with the game for achieving training purposes [16-18]. Previous studies have shown that exergame-based interventions improve both physical aspects (eg, balance, gait, and physical fitness) and cognitive domains (eg, executive functions, memory, and processing speed) in older adults while also facilitating enjoyment and motivation, which are critical mediators of training adherence and goal-directed achievement [19-22]. Nowadays, many commercial interactive game-based training products have emerged, such as Kinect Xbox, Nintendo Wii, Sony PlayStation, virtual reality systems, and computer vision–based applications. Amid the exergames in the commercial market, human pose estimation, which is one of the computer vision–based platforms, has rapidly developed in recent years. Specifically, human pose estimation involves extracting an individual's joint positions from an image or video to create a skeletal shape. With this, an algorithm of machine learning creates a human pose estimation model based on dataset samples of human movements in space, which ultimately enables machines to correctly interact with individuals [23,24]. One interesting feature of computer vision–based systems using human pose estimation is that they are markerless full-body trackers that enable users to naturally interact with games in real time. Additionally, it is reliable for representing a person's movements, resulting in proper feedback and guidance to the users during exercise [25]. Its advantages include its low cost, user-friendliness, simpler operation, and the requirement of only a personal computer, thereby increasing accessibility. Therefore, a computer vision–based system appears to be a viable alternative to delivering home-based exercise programs for older adults.

The ADDIE model is an instructional systems design framework used to design and develop learning experiences that involve identifying the requirements and understanding the solutions that learners should achieve [26]. The ADDIE model comprises 5 phases: analysis, design, development, implementation, and evaluation [27]. There has been growing interest in using the ADDIE model to develop health services for various purposes [28-32]. However, previous works utilizing the ADDIE model to develop exergames aimed at enhancing physical and cognitive functions are scarce. Considering the usability challenges faced by older adults, developers should design exergame interfaces that are user-friendly for this population. Aside from the technologies used, commercial exergames available in the market may not be specific for older people in terms of training purposes, complexity, intensity, and safety. Thus, the ADDIE model may be a useful approach for designing and developing exergames for older adults, particularly in a home environment.

Collectively, a game-based, combined physical-cognitive training that is accessible and user-friendly, boosts motivation, and is tailored to suit older adults' capabilities would represent an efficient approach in terms of time and resources. Therefore, this study focused on developing the prototype of a home-based, low-intensity, gamification-based, interactive physical-cognitive training for older adults using the ADDIE model. Notably, the usability of the system and participants' satisfaction will be investigated to facilitate practical implementation for community-dwelling older adults.

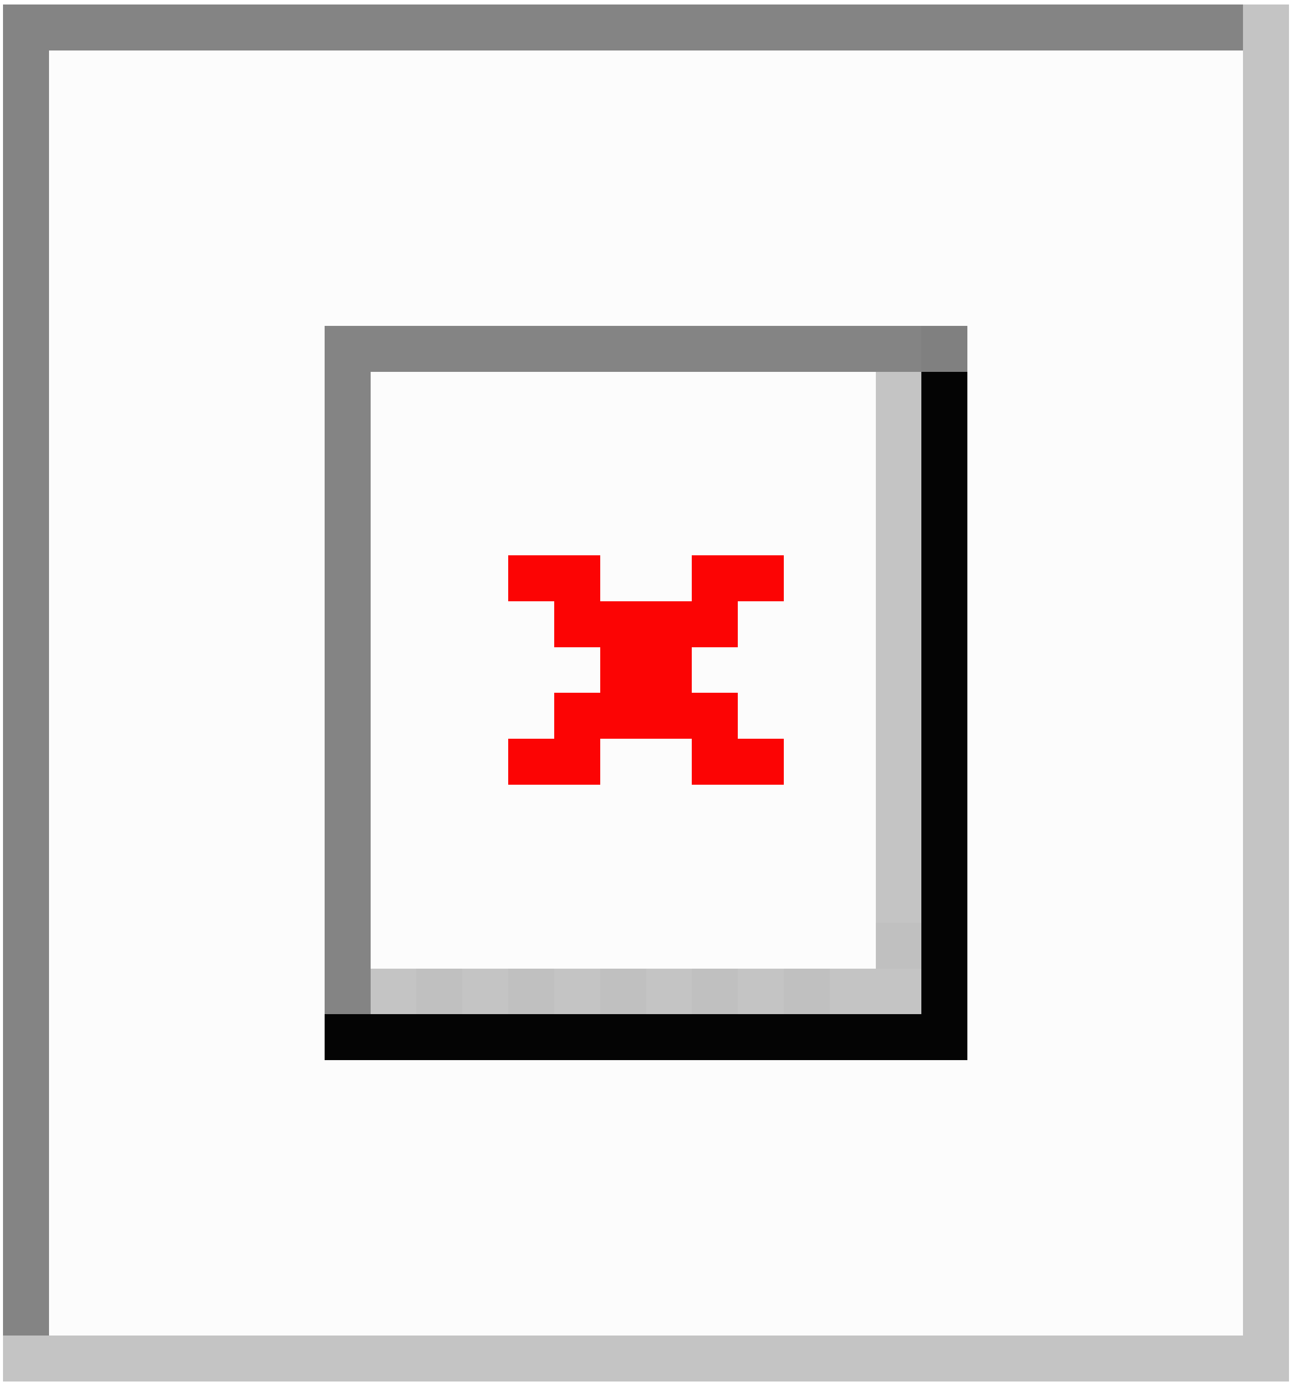
Methods

Study Design

Overview

This study utilized the ADDIE model to design and develop a low-intensity, combined physical-cognitive exercise in the form of an exergame delivered in a home-based format for older adults. The prototype of a gamification-based, interactive physical-cognitive training was built upon five phases: (1) analysis, (2) design, (3) development, (4) implementation, and (5) evaluation of target users' feedback, response, and satisfaction. The ADDIE model is depicted in Figure 1A, and the development milestones of this study are presented in Figure 1B.

Figure 1. (**A**) Development process of the game-based training system using the ADDIE (analysis, design, development, implementation, and evaluation) model. (**B**) Development milestone of the game-based training system prototype.



Phase I: Analysis Phase

During the analysis phase, a focus group expert interview was conducted to extract essential contents in terms of knowledge related to effective physical and cognitive training programs for older adults and potential core game ideas. A total of 7 experts participated in the brainstorming session, including 4 physical therapists and 1 occupational therapist (ages ranging from 38 to 60 years, with 10-25 years of experience in physical and cognitive rehabilitation for older adults, both with and without cognitive impairment), 1 game programmer (29 years old, with 4 years of experience in developing codebases for video games or related software), and 1 game artist (29 years old, with 5 years of experience in developing game mechanics and interfaces).

In this study, the core elements of the exergame consisted of two training components that were trained simultaneously: (1) a physical component at a low intensity level focusing on enhancing dynamic balance, coordination, and muscle strength and endurance of upper and lower limbs, and (2) a cognitive component focusing on memory, attention, and executive function (eg, anticipation, planning, switching, and inhibition) that closely related to balance and falls in older adults [2,33].

Regarding the delivery platform, a computer vision–based system was selected due to its low cost, accessibility, and simple operation, allowing older adults to independently administer self-training at home.

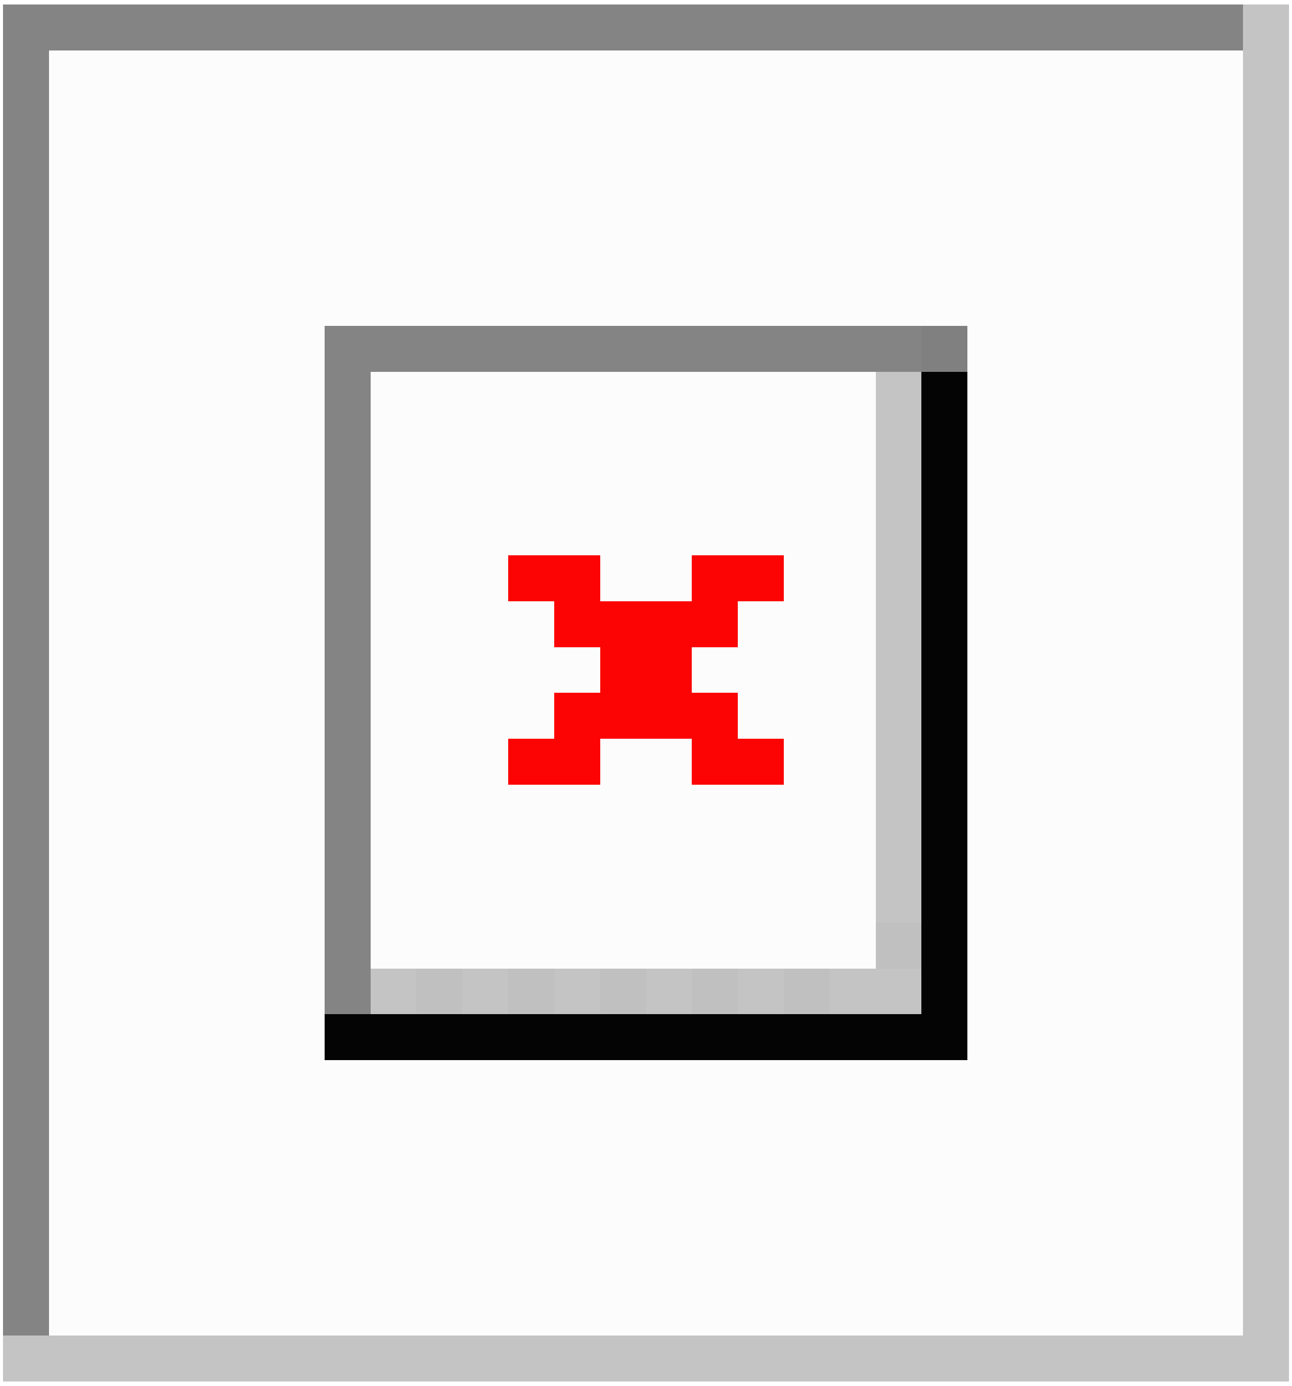
Phase II: Design Phase

In the design phase, the overall game structure and characteristics, including the game's goals, mechanics, and graphical user interface elements, were integrated and fine-tuned from a practical standpoint to form a design of the game-based training system prototype. Moreover, the progression of game difficulty was divided into 3 difficulty levels (ie, beginner, intermediate, and advanced) to ensure that the difficulty of the games was appropriate for each user. After that, the game blueprint underwent a critical review (using the assessment form found in Multimedia Appendix 1) by 5 experts in the field of cognitive and physical interventions for older adults, including 2 physical therapists, 1 occupational therapist, 1 neurologist, and 1 geriatrician, with ages ranging from 40 to 56 years and experience ranging from 18 to 34 years. The content validity of the exergames was analyzed using the index of item-objective congruence (IOC). The cutoff value is a flexible criterion, with a generally accepted minimum typically being 0.75 [34].

Phase III: Development Phase

Consensus on the game idea and design, along with comments and feedback from the experts during the design phase, was used to refine the game-based exercise prototype in the development phase. This prototype was created using the Unity 3D game engine software, incorporating computer vision techniques from BlazePose for 2D/3D pose estimation [35]. The landmarks of the BlazePose 2D/3D pose estimation, which include 33 key points, are provided in Multimedia Appendix 2. In this study, only 12 key points (of 33 points) were utilized to control the mechanics of the games. These key points included the following: (1) left_shoulder, (2) right_shoulder, (3) left_wrist, (4) right_wrist, (5) left_pinky, (6) right_pinky, (7) left_index, (8) right_index, (9) left_thumb, (10) right_thumb, (11) left_hip, and (12) right_hip. The various conditions for controlling the game's avatar are displayed in Figure 2.

Figure 2. Condition of each landmark for control of the avatar in the game. (A) and (B) Moving bilateral arms horizontally to swim in a frog stroke style. (C) Dropping bilateral arms to rest. (D) and (E) Moving bilateral arms as if running to control the forward movement. (F) Raising the left or right hand over the head to collect objects. (G) Raising the right hand over the head to select choice A. (H) Raising the left hand over the head to select choice B. (I) Raising both hands over the head to select choice C.



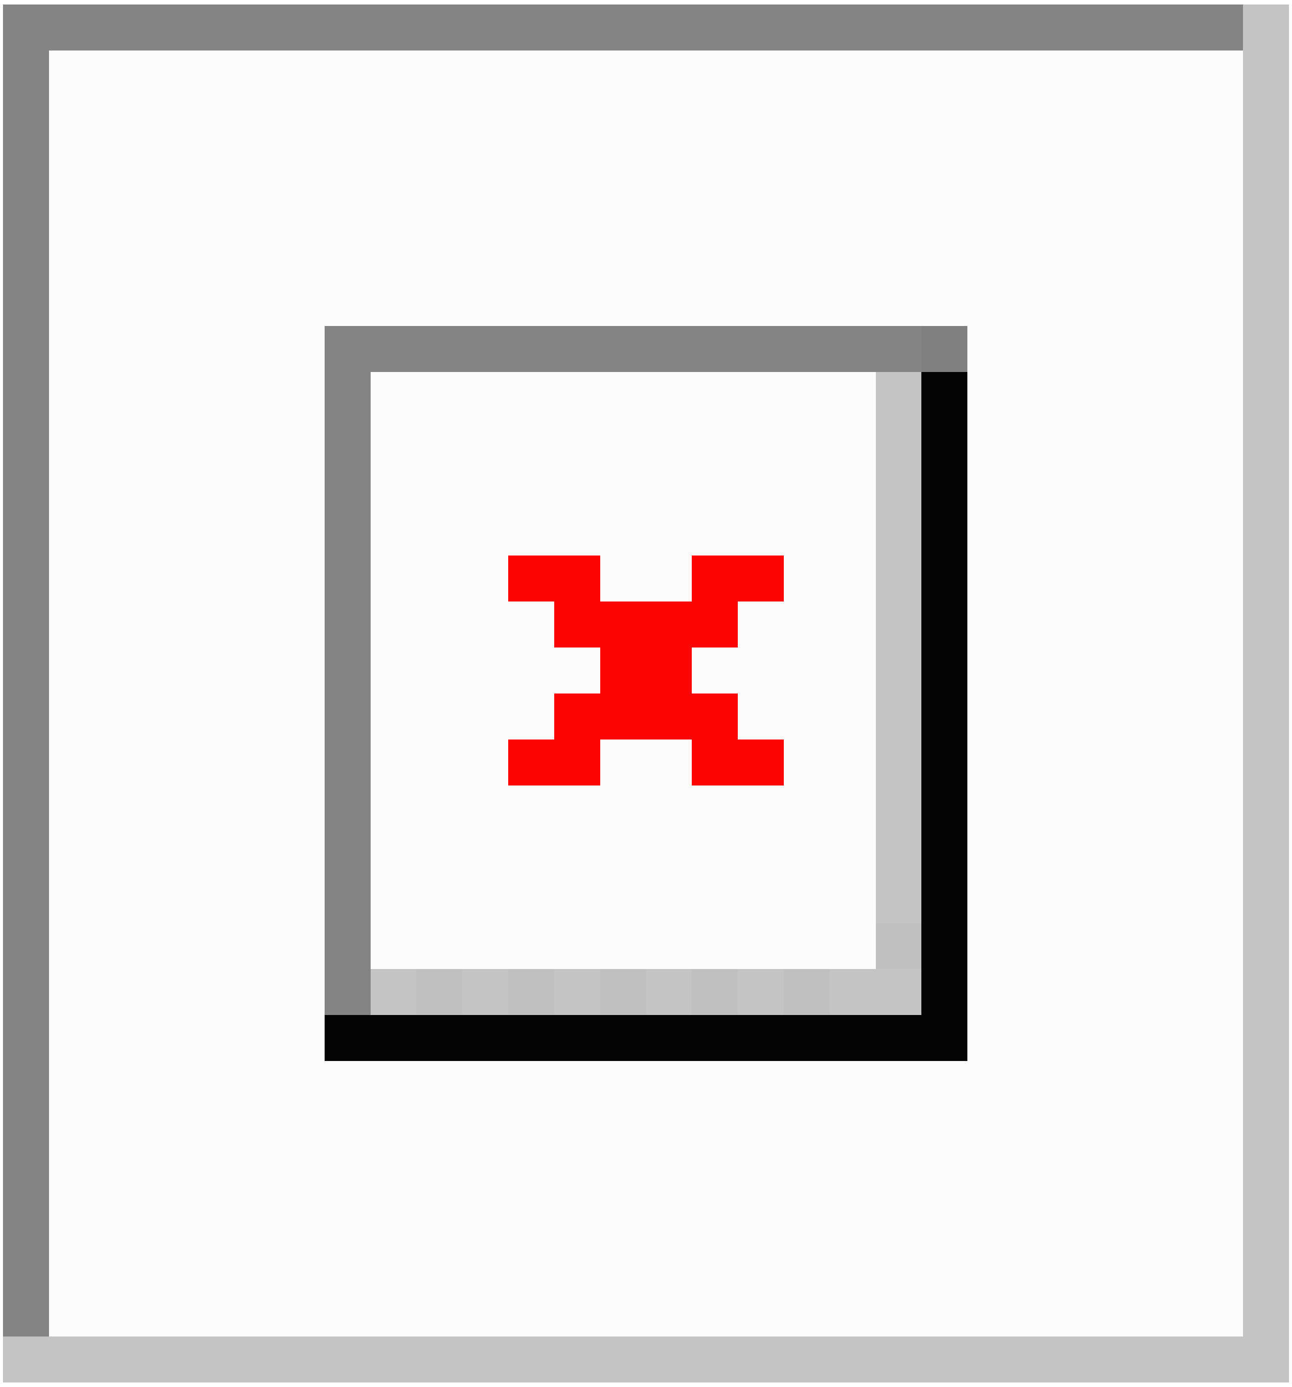
After completing phases I-III, the overall framework of the gamification-based, interactive physical-cognitive training system prototype, consisting of 5 components, was established (Figure 3):

1. User and the notebook with high-definition (HD) webcam sensor: The full-body movements were tracked in 3D coordinates (ie, the x-, y-, and z-axes) using 12 key points (Figure 2). The HD webcam sensor was used to track the full-body movements of the participants while they played the exergame (Figure 3A).
2. The gamification-based physical-cognitive training system: The digital game system consisted of 3 exergames (Game I: Ocean Diver; Game II: Road Runner; and Game III: Moving and Memorizing) with 3 levels of difficulty (beginner, intermediate, and advanced) and feedback (score, time, and error). Moreover, rules, goals, rewards, points, aesthetics, leaderboard, and game mechanics were used as elements of the game. The game was developed using the Unity game engine (Figure 3B).
3. Game programmer: The specialist who created the game using computer programming languages and game engine

software, including level design, coding, game development, and game testing (Figure 3C).

4. Game artist: The specialist who designed and created graphical content, including the graphical user interface, character, scenes, background, sound, and music (Figure 3D).
5. Domain knowledge: The experts with core knowledge in physical and cognitive training programs for older adults, both those with and without cognitive impairment (Figure 3E).

Figure 3. Gamification-based, interactive physical-cognitive training framework: (**A**) user interface and laptop with a camera, (**B**) system of gamification-based physical-cognitive training, (**C**) game programmer, (**D**) game artist, and (**E**) domain experts.



Phase IV: Implementation Phase

Overview

In this phase, the prototype of a low-intensity, gamification-based, interactive physical-cognitive exercise was implemented to representative target users to evaluate its usability and ability to promote enjoyment. The prototype of the exergame was delivered via the Windows platform and devices, including notebooks and personal computers.

Recruitment and Participants

A total of 15 community-dwelling older adults were recruited from community groups such as local senior schools and senior clubs, as well as through social media advertisements. Inclusion criteria were as follows: (1) age 60 years or older, (2) ability to comprehend instructions and willingness to participate, (3) adequate vision and hearing, or correction for impairments, and (4) sufficient physical performance, indicated by scoring at least 9/12 on the Short Physical Performance Battery, to ensure safety during exercise, particularly to prevent loss of balance and falls (Multimedia Appendix 3) [36]. Exclusion criteria were as follows: (1) being diagnosed with other neuromuscular conditions that affect cognitive function and physical ability (eg, stroke, Parkinson disease, dementia, and multiple sclerosis), and (2) having major health conditions that could not be controlled (eg, acute joint pain, asthma, hypertension, diabetes mellitus, and coronary artery disease).

Procedures

System Setup and Calibration

Prior to participants beginning the interactive exergame training at their homes, the researchers made a home visit for the system's setup, calibration, and operation. The capture volume was configured using a notebook or personal computer equipped with an HD webcam. The HD webcam was positioned on a table approximately 0.8 meters above the floor and about 2.5 meters away from the participant. The capture volume from left to right was set at approximately 3.0 meters, with the center being 1.5 meters from each side. The game was displayed on either notebook screens or computer monitors. The configuration of hardware for playing the game is provided in Multimedia Appendix 4. The game-based exercise was connected to the HD webcam sensor in the notebook or personal computer. During the calibration process, participants were instructed to move the avatar within the capture volume, with the boundaries marked by markers on the floor. Once the system had been fully set up, participants were able to use it independently.

User Experience Testing

The demographic information of eligible participants—including age, gender, BMI, and education level—was documented. The game goals, rules, mechanics, and controls were explained to the participants and they were provided with a demonstration. The participants interacted with the virtual game using their body and hand movements following each game's rules (ie, Ocean Diver, Road Runner, and Moving and Memorizing). The training duration was 35 minutes, which included warm-up and cool-down periods, with a rest interval of approximately 5 minutes, resulting in a total session time of around 60 minutes. Participants were allowed to progress to the next level if they achieved a score exceeding 50% in the current level. To assess the usability and enjoyment of the prototype, participants engaged in game-based training at their homes 3 times per week for 4 consecutive weeks (a total of 12 sessions).

Phase V: Evaluation Phase

Participants were asked to provide ratings for both the system's usability and their enjoyment during engagement with the game-based prototype after completing the 4-week testing period. The usability of the game-based physical-cognitive training system was assessed using the system usability scale (SUS) at the end of the training period [37]. The SUS rating scale was then converted from the original score (between 0 and 60) to an SUS score ranging from 0 to 100, where an SUS score above 68 is considered an above average ("good") or marginal acceptance level, and scores above 85 are considered an "excellent" acceptance level [38]. Additionally, the level of enjoyment during exercise engagement was assessed after the first and fourth week of training using the 8-item Physical Activity Enjoyment Scale (PACES) questionnaire, a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree) [38]. The sum of PACES scores was calculated, with a higher score indicating a greater level of enjoyment during exercise engagement. Moreover, participants were interviewed about their perceptions of various aspects of the exergame during gameplay using probing questions (Multimedia Appendix 5). In the interview, assessors asked core questions sequentially and documented the responses. Upon completing the questioning, assessors summarized the key insights from the interview to ensure a comprehensive understanding of the participant's responses. Afterward, assessors extracted key themes from the responses provided by all participants to gather both positive and negative feedback, as well as information for improvements and refinements.

Ethical Considerations

The research protocol received approval from the Human Ethical Review Board of the Chiang Mai University (approval number AMSEC-66EX-036). All participants were informed about the study's purpose and procedure before providing written informed consent to enroll in the study. All data used for this study were anonymized. No compensation was provided to the participants.

Statistical Analysis

The content validity of the exergames, as assessed by experts, was determined using the IOC, with an IOC value greater than 0.75 indicating an acceptable level of validity. Descriptive statistics were used to illustrate the demographic profile of the participants and the SUS score after 4 weeks. The Wilcoxon signed-rank test was used to address differences in the PACES scores between the first week and the end of the 4-week training period. The significance level was set at $P<.05$. Analysis was conducted using SPSS (version 21.0; IBM Corp).

Results

Phase I-III: Analysis, Design, and Development Phases

The game-based training system underwent a critical review by 5 experts in the field of cognitive and physical interventions for older adults. The results indicated that the content validity was highly acceptable, with IOC values ranging from 0.80 to 1.00. The summary of the consensus features of the low-intensity, gamification-based, interactive physical-cognitive exercise is presented in Table 1 and Textbox 1. This system consisted of 3 exergames (Ocean Diver, Road Runner, and Moving and Memorizing), all aimed at enhancing simultaneous physical and cognitive function in older adults. Each exergame had 3 levels of difficulty (beginner, intermediate, and advanced), in which game complexity progressed by increasing the complexity of physical and cognitive demands. The total game play time was 35 minutes. In accordance with exercise principles, warm-up and cool-down sessions were included as part of the training. The exergame prototype was delivered via a computer vision–based system that participants could operate independently in a home-based setting.

Table . Summary of the features of the developed gamification-based, interactive physical-cognitive training.

	Game I: Ocean Diver	Game II: Road Runner	Game III: Moving and Memorizing
Actions	Swimming in a frog stroke style underwater to collect predetermined objects in the correct order and collect coins as a bonus	Running along the road to collect as many predetermined objects as possible and collect coins as a bonus	Walking along the road to collect coins while listening to a story, then answering questions related to the story at the end of the game
Rules and game mechanics	• Moving bilateral arms in a frog stroke style to control the avatar's upward or downward direction • Stepping to the left or right to control the avatar's left or right movement direction	• Moving bilateral arms as if running to control the avatar's forward movement • Stepping to the left or right to control the avatar's left or right movement direction • Raising the left or right arm to control the avatar to collect predetermined objects	• Stepping to the left or right to control the avatar's left or right movement direction • Listening to a story and collecting coins as a bonus • Answering questions related to the story at the end of the game
Virtual environment	An underwater world with aquatic animals and treasures	A suburban village with fruits, vegetables, and animals	A suburban village with coins
Goal of the game: physical components	• Improve dynamic balance and coordination of upper and lower limbs • Improve upper and lower limb muscle strength and endurance	• Improve dynamic balance and coordination of upper and lower limbs • Improve reaction and response time • Improve upper and lower limb muscle strength and endurance	• Improve dynamic balance • Improve lower limb muscle strength and endurance
Goal of the game: cognitive components	Improve memory, attention, and executive function (ie, planning, sequencing, and inhibiting)	Improve memory, attention, and visuospatial ability	Improve memory (delayed recall) and attention

Textbox 1. Framework of the gamification-based physical-cognitive training.

- Physical component training progression: the difficulty levels progressed by increasing the subject's movement speed of upper and lower limbs (eg, adding the number of objects).
- Cognitive component training progression: the difficulty levels progressed by increasing the subject's cognitive demands to play the game (eg, adding memory and attention requirements, increasing the speed of processing, and adding the number of objects).
- Rewards: points and coins
- Estimated playtime: 35 minutes
- Health topic: gamification-based physical-cognitive training prototype
- Targeted age group: older adults (age ≥60 years)
- Short description of the gamification-based training: gamification-based physical-cognitive training is an interactive game-based training system for older adults using high-definition webcam sensor technology. It comprises 3 games involving physical training (ie, dynamic balance; coordination; reaction and response time; and upper and lower limb muscle strength and endurance) and cognitive training (ie, memory or delayed recall, attention, and executive function including planning, sequencing, inhibiting, visuospatial ability.
- End user or target player: older adults (individual self-training)
- Clinical support needed: physical therapists and related geriatrics health care professionals
- Data shared with clinician: data are saved and stored on the hard disk; however, points and scores are given as feedback on the laptop monitor at the end of each game.
- Type of game: physical, cognitive, action, real-time strategy
- Behavior change procedure used: gamification-based physical-cognitive training enhances extrinsic motivation and engagement in older adults.
- Setting: gamification-based physical-cognitive training can be set in a room environment.
- Device requirements: PC/notebook/laptop with HD webcam
- Sensors used: HD webcam

Phase IV-V: Implementation and Evaluation Phases

Participant Characteristics

In total, 15 community-dwelling older adults aged ≥60 years took part in the study; of the participants, 8 were female and 7 were male. None of the participants had prior experience with game-based training. The demographic characteristics of the participants are presented in Table 2. All participants completed the training program (mean number of exercise sessions 11.07, SD 1.95, with a total of 12 sessions). No falls or other adverse events were reported.

Table . Characteristics of the study participants.

Characteristics	Mean (SD)	Range (minimum-maximum)
Age (years)	65.27 (4.40)	64.00 - 77.00
BMI (kg/m^2)	24.09 (2.59)	20.03 - 28.73
Education level (years)	15.67 (2.58)	9.00 - 21.00

User Experience in Using the Gamification-Based Exercise System

The user experience in using the game-based exercise was determined using the SUS questionnaire and the PACES. The overall results of the SUS score are illustrated in Figure 4. The mean SUS score was 87.22 (SD 5.76), which corresponds to an A or "excellent to highest possible" acceptance level (based on the grade scale and adjective rating; Figure 4A). Further data exploration showed that, of the 15 participants, 6 rated this gamification-based exercise system prototype as "good," 5 rated it as "excellent," and 4 rated it as "highest possible." The mean SUS score for each question ranged from 72.22 (question item 6) to 98.89 (question item 3), signifying ratings from a marginal "good" to the "highest possible" acceptance level (Figure 4B).

As for the 8-item PACES score, the total PACES score of all items at the end of the first week of training was 44.93 (SD 3.99); the average on each item ranged from 5.27 to 5.93. After 4 weeks, it was 50.53 (SD 4.70); the average on each item ranged from 5.93 to 6.67 (Table 3). A Wilcoxon signed-rank test demonstrated that both the average on each item and total score after the 4-week training were significantly greater than those after 1 week of training (P=.001), indicating an improvement in enjoyment and satisfaction after exercise engagement for 4 consecutive weeks.

Figure 4. Overview of usability results of the game-based exercise prototype using the SUS questionnaire at the end of the 4-week testing period. (A) The SUS score and its relationship with the grade scale (F, D, C, B, and A), adjective ratings (lowest possible, poor, okay, good, excellent, and highest possible), and acceptability scores (with marginal acceptability at 68.0). (B) The SUS score for each question. SUS: system usability scale.

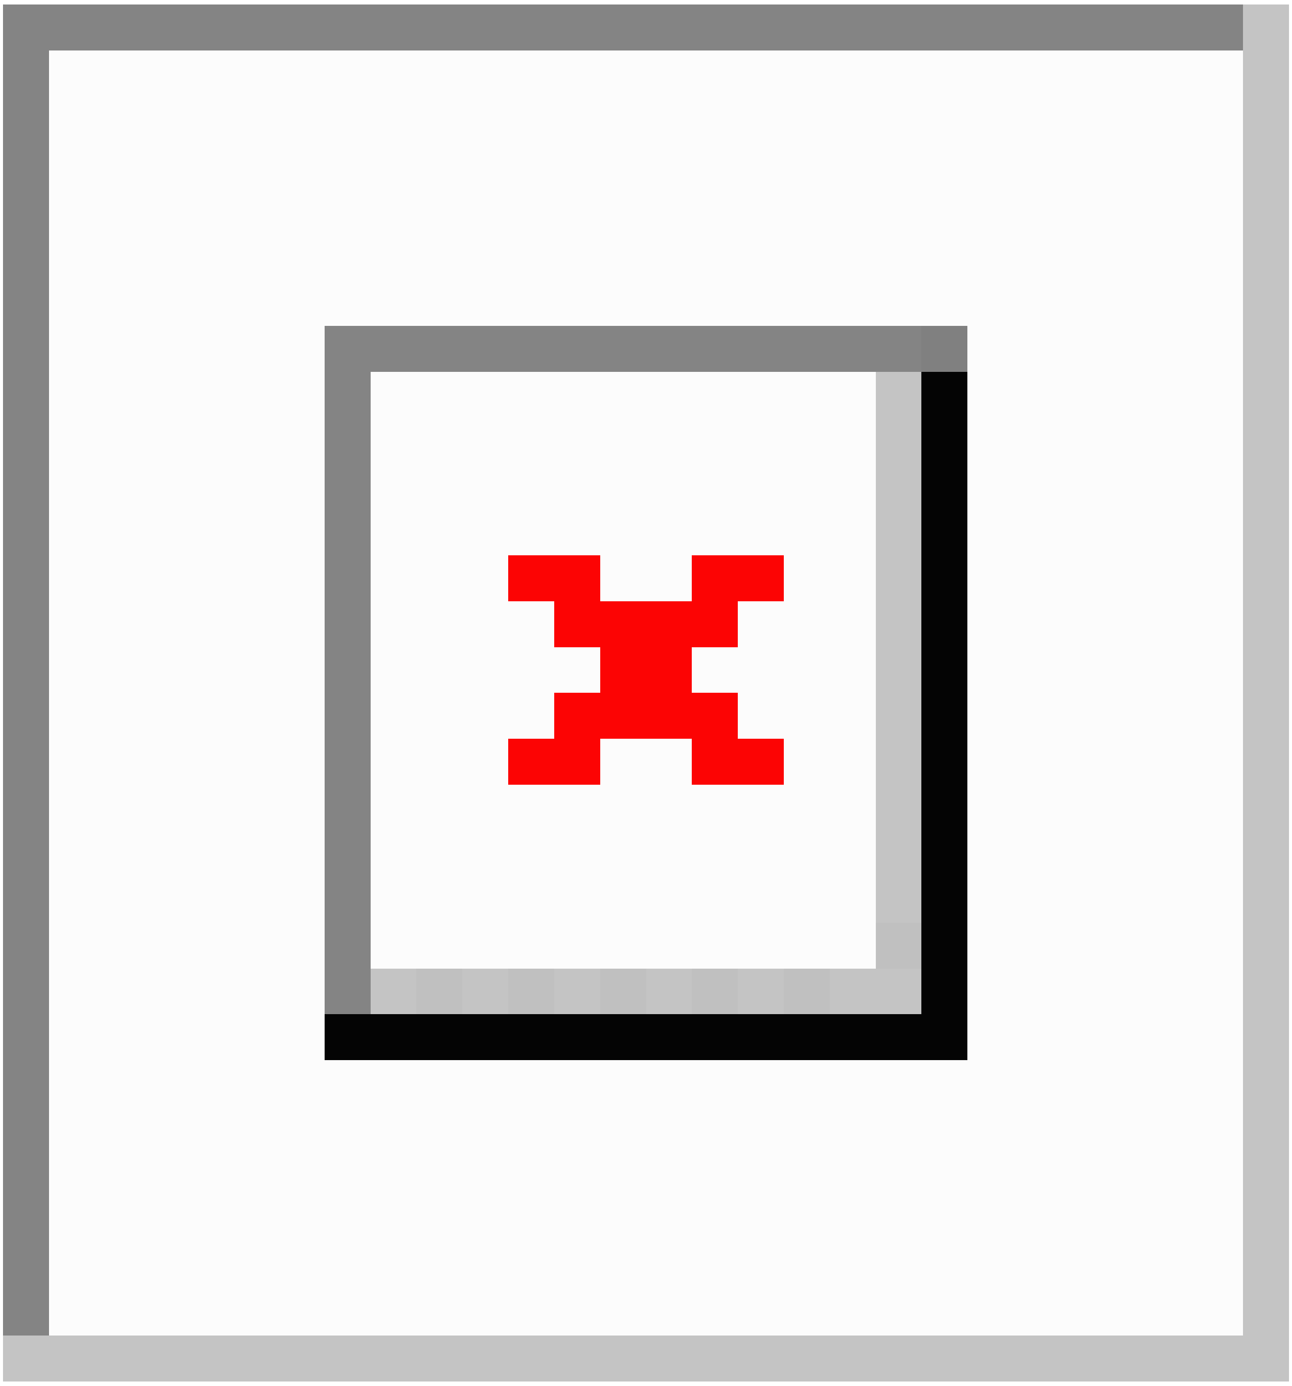


Table . The PACES score after 1 week of training and after completion of 4 weeks of training (n=15). All items were rated on a 7-point scale from 1 (strongly disagree) to 7 (strongly agree).

Question items	Week 1, mean (SD)	Week 4, mean (SD)	*P* value[a]
1. I find it pleasurable	5.53 (0.83)	6.33 (0.82)	.003
2. It's a lot of fun	5.27 (0.88)	5.93 (0.88)	.02
3. It's very pleasant	5.27 (0.88)	6.27 (0.88)	.002
4. It's very invigorating	5.60 (0.63)	6.13 (0.83)	.01
5. It's very gratifying	5.67 (0.62)	6.27 (0.70)	.01
6. It's very exhilarating	5.73 (0.59)	6.40 (0.74)	.004
7. It's very stimulating	5.93 (0.59)	6.53 (0.52)	.01
8. It's very refreshing	5.93 (0.59)	6.67 (0.62)	.005
Total scale of all items (56 points)	44.93 (3.99)	50.53 (4.70)	.001

[a]Wilcoxon signed-rank test with significant difference at $P<.05$.

User Feedback of the Gamification-Based Exercise System

Comments and feedback from the participants on the developed gamification-based exercise system prototype through probing interviews are summarized for each question domain in Table 4.

Table . The key responses of participants regarding the game characteristics and their perceptions during engagement with the game-based prototype.

Question domains	Positive feedback	Negative feedback
Game mechanics, rules, and interface	• The storytelling game (Moving and Memorizing) was enjoyable, with its content, purpose, and display perfectly suited to personal preferences • The Ocean Diver game was very enjoyable and well-designed, providing a refreshing experience	• It is hard to judge how far to jump to grab animals or objects on time • Sometimes in the game, the movements did not align with the actual actions • The characters and objects displayed in the game were relatively small • Sometimes, the game system froze
Game instructions	Instructions for the game were clear and easy to understand	No negative feedback
Gameplay experience	• The exergame was very helpful as it promoted physical activity and memory • The exergame could be played at any time, which perfectly fits the schedule • There was a noticeable improvement in sleep quality	• In the Ocean Diver game, some objects that needed to be collected were placed in tight spots, making it stressful when participants were unable to pick them up
Exercise dosage	The exercise was not too difficult, as it allowed me to keep up with the training	In the first week of training, the legs were quite fatigued; however, after the first week, it went away
Feedback for improvements	Overall, the games were satisfying, enhancing both enjoyment and physical activity	Making the movements in the game better match the user's actions, increasing the size of the characters and objects, and reducing the game system's freezing issues

Discussion

Principal Findings

This study aimed to design, develop, and determine the user experience of a prototype of low-intensity, gamification-based training targeted at improving physical and cognitive performance in older adults within a home environment using the ADDIE model. The idea of the core concept and platform of the exergame were extracted by integrating the knowledge with well-recognized physical and cognitive outcomes in older adults, considering practical standpoints, and then soliciting critical appraisal by experts. The content validity of the exergames was highly acceptable, demonstrating that the game's features, rules, and exercise components were well-aligned with both the intended therapeutic goals and practical considerations. The experiences of older adults in terms of usability and enjoyment of the exergame prototype were assessed and their feedback was collected.

The output of this study was the prototype of a gamification-based, interactive physical-cognitive training program in a home-based setting, which consisted of 3 exergames: Ocean Diver, Road Runner, and Moving and Memorizing. Each game had 3 levels of difficulty: beginner, intermediate, and advanced. The user-perceived usability of the game-based exercise prototype was rated as good to excellent, and there were improvements in enjoyment and satisfaction after exercise engagement over 4 consecutive weeks. Additionally, the overall end user feedback indicated that the motivation for engaging in an exergame is its inherent interest and enjoyability.

Comparison to Prior Work

In recent years, an increasing number of studies have developed and evaluated the effects of exergames on both physical and cognitive functions in older adults. However, the majority of these studies have used moderate-to-high physical intensity levels [19,39,40], which are generally suitable for relatively healthy individuals without significant physical restrictions. Only a limited number of studies focused on developing low-intensity exergames, which may be more practical for older adults who are physically limited or less active, as they require low exertion and low-impact exercise modes. To the best of our knowledge, our game-based exercise is the first prototype of low-intensity, gamification-based, interactive physical-cognitive training specifically designed to enhance both physical and cognitive abilities in older adults. We found that the exergame prototype was usable in a home environment and effectively enhanced the enjoyment and motivation of older adults. The feedback also indicated potential future applications for self-training at home. These findings are in line with previous studies suggesting that computer-based interventions, a delivery platform used in this study, offer a practical, safe, and efficient approach to encouraging adherence to exercise [41,42].

Currently, various approaches to product development may involve end users at different stages of the production process, depending on the specific product requirements and goals. Among various product development approaches, the ADDIE model was selected because it aligns well with our exergame product, which is relatively new and unfamiliar to older adults. This model involves experts in the analysis and design phases (phases I and II) and end users in the implementation and evaluation phases (phases IV and V). Given that experts have knowledge and experience in the fields of physical and cognitive rehabilitation for older adults, as well as game development, they played a key role in the analysis and design phases, which are crucial for achieving both theoretical accuracy and practical feasibility to ensure high-quality outcomes. A representative group of the end users (older adults) tested the exergame prototype and provided feedback during the implementation and evaluation phases. The feedback and suggestions from end users were essential in shaping the final product, guaranteeing that the prototype was closely tailored to their needs and preferences. A previous study suggested that individualization of the exercise in terms of needs and interests is necessary to enhance individual engagement, thereby contributing to positive intervention outcomes [43]. In addition, this study utilized a computer vision–based system as a technology platform to deliver an exercise program (in the form of an exergame) in a home-based environment, aiming to provide accessibility and ease of integration into users' lives. Previous findings have suggested that home-based exercise exerts greater exercise engagement than center-based exercise due to its accessibility and flexibility in the schedule, allowing individuals to integrate it conveniently into their daily life [44,45]. Taken together, the benefits of using the ADDIE model approach and delivering the platform as a computer vision–based system for the development of an exergame prototype may represent a potential strategy for enhancing the enjoyment, motivation, and engagement of older adults in exercise in a home-based setting.

Regarding the user experience with the game-based training system, participants reported increased enjoyment, as indicated by their PACES scores, and provided positive feedback on the enhancement of both their enjoyment and physical activity. The increase in the enjoyment level of participants may, at least in part, be attributed to several fundamental aspects of the game. These include game elements that provide real-time feedback (ie, scores and rewards), game mechanics (ie, real-time interface and sound effects), and game rules (optimal difficulty level, grading from simple to advanced), which in turn results in high enjoyment and self-efficacy empowerment. Our findings are supported by prior research, which suggests that intrasession feedback, positive reward, and the use of graded exercise may enhance intrinsic motivation and self-confidence in the capability to exercise, potentially reinforcing repetitive desirable behavior [46,47]. Some negative feedback on the game's characteristics was received, including issues with asynchronization between user actions and the display, system freezing, and the need to enlarge characters and objects. Thus, additional adjustments to the game mechanics are necessary prior to its deployment for end users. Apart from the game characteristics, the usability of a game-based system is a key aspect in enhancing acceptability and exercise adherence. As we found, the users' perception of the usability of the developed game-based training system, as determined by the SUS score, ranged from good to highest possible. The positive response from usability testing may potentially be due to the game interface and operations being specifically designed to be used independently by older adults. Consistently, a previous study has suggested that the feature design of exergames, particularly an interface that is friendly to older users, is a crucial factor contributing to the positive acceptance of older users who are unfamiliar with new technology [48]. Nonetheless, the lowest scores on the SUS questionnaire were found in items 5 and 6 (scoring 74.44 and 72.22, respectively), which are related to game mechanics and consistent with feedback for improvements. Therefore, further refinement of the exergame system is warranted before implementation for end users, particularly concerning technical errors and game mechanics issues encountered by participants.

Strengths and Limitations

To the best of our knowledge, this game-based home exercise is the first prototype customized for older adults with low physical capacity, aiming to simultaneously stimulate specific cognitive domains and physical components. Despite the positive results, this study has certain limitations that need to be addressed. First, participants in this study had relatively high educational backgrounds and were socially active, which may introduce potential bias, as they may be more familiar with technology. Further, they did not exhibit obvious physical restrictions as the study inclusion/exclusion criteria were set to minimize potential adverse events during participation. Second, the sample size was relatively small. Together, the findings may not be generalizable to a broader older adult population and should be considered preliminary, warranting cautious interpretation. Third, exercise adherence was observed over a 4-week training period; hence, long-term adherence remains unknown. Last, since this study focused on developing and assessing the usability of an exergame prototype for home-based settings, hard outcomes, such as physical and cognitive parameters in response to exergame engagement, have not yet been established. Further research that includes larger sample sizes, diverse demographic backgrounds, extended training periods, and examination of effectiveness through comprehensive outcomes is needed.

Future Directions

The outcome of this study is the prototype of a home-based, low-intensity exercise program that is practical and has the potential to enhance the enjoyment and motivation of older adults. The next step will be to refine the game-based prototype based on end user critical feedback and examine its effectiveness in promoting the physical and cognitive functions of community-dwelling older adults, thereby giving this new type of exergame a promising future.

Conclusions

In this study, a low-intensity, gamification-based, interactive physical-cognitive training system was developed for older adults with limited capacity to engage in moderate-to-high intensity exercise. The exergame prototype, delivered via a computer vision–based platform for a home-based, self-training exercise, was well-received by the end users for its usability and enjoyment. Although these findings hold promise for implementing the exergame in the target population, further research is warranted to determine its effectiveness in promoting physical and cognitive functions.

Acknowledgments

The authors would like to thank Nathapong Metawatcharekul and Thanet Galong for their contribution to the development of the exergames, and Poosri T for her assistance with data collection. The authors would also like to thank participants for their engagement and feedback. Special thanks to all the experts for their comprehensive comments in the development of the exergame prototype. This study has been funded by the National Research Council of Thailand (NRCT; N42A660640) and the Faculty of Associated Medical Sciences, Chiang Mai University (author SS).

Data Availability

The datasets generated and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

KT, KS, MP, BS, and SS contributed to the study conception and idea, experimental design, data collection, and approval of the final manuscript for publication. KT was responsible for intellectual contributions related to gamification for health, research planning, data analysis and interpretation of the results, and drafting the manuscript. SS and BS were responsible for intellectual contributions related to exercise sciences for older adults, data analysis and interpretation of the results, drafting the manuscript, and reviewing the final manuscript.

Abstract

Background: Knee osteoarthritis prevalently causes significant pain, activity limitations, psychological distress, and reduced quality of life. Despite lower limb strength training being a core treatment for knee osteoarthritis, adherence remains a challenge, prompting the exploration of virtual reality (VR) to improve exercise compliance. Recent research suggests the potential of VR in providing enhanced pain management and functional outcomes for knee osteoarthritis, necessitating further exploration of immersive VR technology.

Objective: We aimed to study the feasibility, acceptability, and preliminary efficacy of an immersive VR-assisted lower limb strength training for knee osteoarthritis (VRiKnee).

Methods: A convergent, parallel, mixed methods study was conducted in 30 participants with knee osteoarthritis. After 1:1 randomization, the VRiKnee group (n=15) was assigned to perform repetitive concentric quadriceps and isometric vastus medialis oblique exercise in an immersive environment using a head-mounted display for 12 weeks. The control group (n=15) completed the same exercises without VRiKnee. VRiKnee participants were interviewed at week 12 to study VRiKnee acceptability and user experience. Quantitative data included feasibility outcomes such as recruitment, dropout, and exercise adherence rates, and effectiveness outcomes such as the numeric rating scale, the Western Ontario and McMaster Universities Osteoarthritis Index (100 points) pain and function subscales, and objective physical activity measured by metabolic equivalents of task using an ActivPAL accelerometer. Qualitative data were analyzed by thematic analysis, followed by integration with quantitative data using joint displays.

Results: The recruitment rate was 100% (N=30), with enrollment of 30 participants in 7.57 weeks. The median age was 63.5 (IQR 61.8 - 66.3) years, with 76% (n=23) being female. The response rates were 80% and 93% for the VRiKnee and control groups. Dropout rates were 13% for VRiKnee and 7% for the control group. Median exercise adherence was 77% (IQR 37-104%) for VRiKnee and 62% (IQR 40-166%) for the control group, respectively, with adherence reduction over this study's period and no significant intergroup differences (P=.82). No statistically significant differences were observed in primary and secondary outcomes, though positive trends were observed in pain and stiffness. Cybersickness was reported by 5 (33%) participants in the VRiKnee group. In the qualitative analysis, 4 themes, 11 subthemes, and 16 quotes were generated, identifying facilitators and barriers with practical suggestions to enhance the usability of VRiKnee.

Conclusions: VRiKnee demonstrated feasibility, acceptability, and potential efficacy in managing knee osteoarthritis. Future trials of larger sample sizes and better VR designs will confirm its role in clinical practice.

Introduction

Knee osteoarthritis is a common degenerative joint disease with a global prevalence of 22.9% in participants aged 40 years and older [1]. It is a major contributor to disability worldwide, causing considerable pain, activity limitations, psychological distress, and reduced quality of life for those affected [2-4]. According to Osteoarthritis Research Society International in 2019, land-based exercise is a core treatment for knee osteoarthritis, for which lower limbs strength training is often recommended [5-7]. In clinical practice, exercise programs often involve initial supervision by a clinician, followed by unsupervised home exercise. Ideally, regular participation in exercise should be one of the long-term goals for knee osteoarthritis; unfortunately, adherence to home exercise is often poor [8]. Therefore, strategies are needed to improve adherence to home exercise.

Recently, studies have suggested that technology advancements may increase attractiveness of exercise programs, thus further improving its compliance, adherence, and clinical outcomes [9,10]. In this context, innovative approaches, such as virtual reality (VR), have gained attention as potential interventions to enhance exercise adherence and outcomes for participants with knee osteoarthritis. VR is a digital technology that incorporates the use of interactive simulations created with computer hardware and software to present users with opportunities to engage in environments that appear and feel similar to real-world objects and events [11,12]. Within VR applications, an important distinction can be made between immersive and nonimmersive media, which differs in spatial presences [13]. With immersive technology, participants view the full panorama and are essentially inside the created environment. In a nonimmersive environment, virtual content is based on how the device (PC, smartphone, or tablet) is moved or rotated, and participants are only external observers.

An increasing number of trials have demonstrated the positive role of VR-assisted interventions in chronic pain management [14]. VR distracts users from their noxious pain perceptions by shifting their focus into video games, thus increasing their pain tolerance [15,16]. The gaming elements further enhance users' performances and motivation to exercise [17,18]. VR also facilitates skill-building for regulating painful stimuli through stimulating visual, auditory, and proprioception senses [16]. Numerous studies have supported VR-assisted physical therapy in reducing pain and improving function in low back pain and neck pain [19-21]. However, little is known about the effectiveness of VR-assisted physical therapy for knee osteoarthritis. To the best of our knowledge, only 3 trials evaluated nonimmersive VR-assisted balance and proprioception training, and findings suggested its benefits in reducing pain and improving function in knee osteoarthritis [22-24]. Since evidence has highlighted that the exposure to an immersive VR is able to elicit a better sense of presence and potentially impact the effectiveness of VR treatments [25], it is worth to explore immersive VR-assisted physical therapy in the rehabilitation of knee osteoarthritis.

This study aimed to pilot-test the feasibility, acceptability, and preliminary efficacy of an immersive VR-assisted lower limb strength training for knee osteoarthritis (VRiKnee) through a mixed methods approach. We hypothesized that VRiKnee was feasible as a home-based exercise for knee osteoarthritis. The quantitative measures would provide insights into the trend of clinical effectiveness, guiding the design of larger-scale trials, whereas the qualitative measures would uncover potential barriers, enabling the enhancement of future VR interventions.

Methods

Study Design

A convergent, parallel, mixed method study was used to gain an in-depth understanding of feasibility and acceptability of applying immersive VR on our selected population [26]. Quantitative and qualitative data were conducted concurrently in a 12-week, 2-arm, pilot randomized controlled trial design (CHiCTR2100046313). This study was conducted in Hong Kong from June 1, 2021, to March 18, 2022, in 3 separate batches. All collected quantitative and qualitative data were equally weighted, independently analyzed, and then integrated to generate results [26].

Ethical Considerations

This study complied with the Declaration of Helsinki, and ethical approval was obtained from the Joint Chinese University of Hong Kong–New Territories East Cluster Clinical Research Ethics Committee (2021.052). Written informed consent was obtained from all participants. All data were deidentified and kept confidential and were disposed on completion of this study.

Settings and Participants

Participants were recruited from an existing community project titled "CUHK-Jockey Club Pain Relief Project for Seniors," a charity program that offered nonpharmacological pain management to older adults with chronic musculoskeletal pain [27]. The eligibility criteria were screened by a trained research assistant and confirmed by a primary care physician. The inclusion criteria were a diagnosis of knee osteoarthritis based on clinical and radiographic criteria, as defined by the American Rheumatology College; moderate to severe knee pain for at least 3 months; pain intensity score ≥4 on a numeric rating scale (NRS) of 10; and use of a smartphone [28]. The exclusion criteria were decompensated organic and psychiatric disease; contraindications to VR therapy due to history of epilepsy or severe myopia (>−3.5 diopters); and comorbidities that may impede active participation in this study. Participants were recruited in 3 separate batches based on the availability of lower limb sensors.

Interventions

All participants attended a 30-minute health talk led by a registered physiotherapist to explain and demonstrate the home-based exercises. Further, 2 sets of lower limbs strengthening exercise were selected from the Ottawa panel clinical practice guideline and validated by a physiotherapist and a primary care physician [29]. This included repeated knee-extension exercise for concentric quadriceps training and squeezing a fitness ring between the thighs for vastus medialis oblique isometric training, both to be performed in a sitting position.

Participants in the VRiKnee group were instructed to perform lower limb exercises for 12 weeks using an immersive VR platform developed by our team. A smartphone app (iOS or Android) which captured outdoor garden scenes was used to create an immersive environment and participants were immersed using a head-mounted display (HMD) device (VR Shinecon 5.0). The app provided a virtual environment with ambient audio, an amateur as a coach, and interactive animations with visual feedback that encourage practice, that is, virtual flowers that would blossom with successful exercise moves and a timer for unlocking the 3 levels of difficulty. The app also recorded participants' accumulated moves, total exercise time, and game level in a virtual scoreboard (Multimedia Appendix 1).

Participants in the control group were instructed to perform the same set of exercises as guided by paper-based education pamphlets. Both groups were advised to perform the exercise 5 days per week, with an expected duration of 30 min/d for 12 weeks. An exercise diary was given to the control group to record exercise participation.

Sample Size Calculation

We applied the stepped rule of thumb in this pilot sample size calculation [30]. With a proposed future main trial design of 90% power and 2-sided 5% significance, a total of 30 participants (15 at each arm) would be able to detect an assumed effect size of 0.5.

Randomization, Allocation, Concealment, and Blinding

An off-site statistician performed 1:1 randomization using Random Allocation Software (version 1.0) to allocate and control groups. The allocation sequence was concealed from investigators and participants using sequentially numbered, opaque, and sealed envelopes. The corresponding envelopes were opened at the time of intervention assignment after all the enrolled participants had undergone all baseline assessments. It was not possible to blind participants and research assistants implementing interventions in this open-label study; however, data collectors and outcome adjudicators were blinded to the allocation status.

Data Collection

The outcome measures were collected through face-to-face interviews at baseline, 6 weeks, and 12 weeks. Demographic data such as age, gender, the number, and type of comorbid illnesses were recorded.

Quantitative Outcomes

Primary Outcomes

The primary outcome was to assess the feasibility of VRiKnee for knee osteoarthritis. Assessments included recruitment rate, dropout rate, response rate, intervention adherence rate, and adverse events. Recruitment rate was defined by the proportion of eligible participants who successfully enrolled into this study. Response rate was the percentage of usable responses obtained from our quantitative data questionnaires, calculated over the number of eligible participants. Dropout rate was the proportion of participants who dropped out of this study before its completion. Intervention adherence rate was measured by the Timeline Followback for Exercise, which is a validated retrospective self-reported calendar that documents exercise participation [31]. It was calculated by the total self-reported exercise time over the expected time spent on lower limb strengthening exercises in this study's period, that is, total exercise time (min) in wk/(30 min per d × 5 d per wk × number of wk). Adverse events or side effects were collected by participants' exercise records at each visit. Success criteria for this pilot study were set with prespecified thresholds of a 60% recruitment rate, a 70% response rate, and a <20% dropout rate.

Secondary Outcomes

Secondary outcomes evaluated the treatment effect at 12 weeks. These included pain intensity, physical function, and health-related quality of life. Pain intensity was measured using the NRS (0 - 10) [32] and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale [33,34]. Physical function was measured subjectively by the WOMAC function subscale [33,34] and objectively by the number of steps captured by ActivPAL monitor (PAL Technologies Ltd). ActivPAL is a thigh-worn accelerometer that distinguishes body posture and movement and provides objective exercise participation measurements [35,36]. Participants were assigned to wear the ActivPAL at their anterior upper thigh for 7 consecutive days at baseline and at 12 weeks, respectively. All ActivPAL data that recorded at least 4 days of activities over 20 hours were considered as valid [37,38]. The metabolic equivalents of task (MET) equation was used to measure the level of physical activities [39]. Health-related quality of life was measured by the EuroQol-5D [40,41].

Qualitative Outcomes

A concurrent approach was used to understand the acceptability toward VRiKnee. All participants were recruited to focus group interviews at 12-week using convenience sampling and qualitative data was collected until theoretical saturation [42]. A licensed counseling assistant (HHKL) with experience in qualitative interviews and a registered nurse (HHML) held the semistructured interviews with open-ended questions (Multimedia Appendix 2) to assess user experience and technology acceptance [43,44]. To engage participants in a dialogue, follow-up questions were asked according to individual responses. Since this study was conducted during the COVID-19 pandemic, both face-to-face and Zoom (Zoom Video Communications, Qumu Corporation) videoconferencing were used for focus group interviews [45].

Statistical Methods and Analysis

Quantitative data were statistically analyzed with IBM SPSS Statistics software (version 28.0.1.1, IBM Corp). Between-group differences were compared with the Mann-Whitney test for continuous variables and the Fisher exact test for categorical variables [46]. Prior to the intention-to-treat (ITT) analysis, missing values were imputed using a Markov chain Monte Carlo model, in which 10 completed data sets were imputed under the assumption that data were missing at random [47-49]. Imputed dependent variables included the NRS, WOMAC, EQ-5D, and MET; imputed independent variables or covariates included gender, number of chronic diseases, and baseline MET. The parameters were combined according to the Rubin rule, and a linear mixed model was used to analyze results. Analysis of covariance was used to assess the intervention effects on secondary outcomes at week 6 and 12 following the ITT analysis, adjusting baseline measurements at randomization [50].

Qualitative data were collected and analyzed with our quantitative data. Each semistructured interview was transcribed verbatim and analyzed using thematic analysis [51]. Further, 2 researchers (HHML and HHKL) read the transcripts line by line to familiarize with the data and initial codes were then formulated. The coding structure was then validated by 2 authors (MN and RWSS) independently. Codes sharing similar meanings were consolidated and organized into potential themes. Thematic maps were generated for review of themes in relation to the coded extract [52]. Similar codes were grouped into categories and themes and were discussed within the research team until consensus was met. We initiated coding and analysis of data early after batch one to identify possible patterns and themes, and qualitative data was collected until theoretical saturation was reached [53]. The researcher reflexivity of this study was enhanced with several strategies [54]. First, the interviews were led by HHKL, a counseling assistant with experience in qualitative interviews; HHML is a registered nurse with experience in older adult care, who participated in observation note taking during the interviews. Second, a reflexive journal was kept throughout the research process to increase transparency. To minimize individual biases, reflexive team discussions were carried out among the research team throughout the interpretation phase. The work was supported by RWSS, a family medicine physician with clinical and research experience, and MN who is an expert on mixed method studies.

Finally, data-mixing occurred when both quantitative and qualitative data were analyzed using side-by-side comparisons and joint displays [55].

Results

Overview

In total, 30 participants with a median age of 63.5 (IQR 61.8 - 66.3) years, 76% (n=23) of whom were female, were recruited. No statistical differences were found between the groups in terms of baseline measurements of variables (all *P* values were >.05). Participants' baseline characteristics are summarized in Table 1.

Table . Participants' baseline characteristics.

Demographic data	Total (N=30)	VR[a] group (n=15)	Control group (n=15)	*P* value[b]
Age (years), median (IQR)	63.5 (61.8 - 66.3)	63 (60 - 67)	64 (62 - 65)	.97
Gender (female), n (%)	23 (76.7)	10 (66.7)	13 (86.7)	.39

[a]VR: virtual reality.

[b]Fisher exact test was used for categorical variables . Mann-Whitney test was used for nonnormal continuous variables.

[c]Participants reported comorbidities including hypertension, diabetes mellitus, dyslipidemia, cerebrovascular disease, indigestion, cataract, hyperthyroidism or hypothyroidism, tinnitus, fatty liver, gall stones, indigestion, constipation, gastritis, cataract, cerebrovascular disease, and cancer.

[d]NRS: numeric rating scale.

[e]WOMAC: Western Ontario and McMaster Universities Osteoarthritis Index.

[f]EQ-VAS: Euro-Qol-visual analogue scale.

[g]One invalid ActivPAL record due to device failure from control group.

Primary Outcomes

Recruitment was conducted between May 27, 2022, to November 3, 2022, in 3 separated batches; the total recruitment time was 7.57 weeks. A total of 100 registrations were received; 29 did not have knee osteoarthritis, 30 did not have smartphones that operate on Android or iOS, and 11 had comorbidities that precluded their participation. The remaining 30 eligible participants were all enrolled to this study and successfully randomized, with a recruitment rate of 100%. The response rates were 80% and 93% for the VR group and control group, respectively. The median exercise adherence for VR and control groups was 78.89% (IQR 47.75%-142%) and 68.75% (IQR 38.57%-188%) during the initial 6 weeks, respectively; both groups had reduced exercise adherence, with rates decreasing to 77.22% (IQR 36.78%-104%) for the VR group and 62.08% (IQR 40.43%-166%) for the control group over the 12 weeks. The adherence rates in terms of bout time are shown in Table 2.

In total, 2 participants dropped out in the VRiKnee group and 1 in the control group, with a dropout rate of 13.3% and 6.7%, respectively. Reasons for dropout included hearing impairment (n=1) and worries for personal health (n=1) in the VR group and emotional distress (n=1) in the control group. Adverse events included 5 (33.3%) participants reporting cybersickness in the VR group. This study workflow is summarized in Figure 1.

Table . Primary outcomes between the intervention and control groups at week 12.

Primary outcomes	VRiKnee[a]	Control	*P* value[b]
Recruitment rate (%)	100	100	N/A[c]
Dropouts, n (%)	2 (13.3)	1 (6.67)	>.99

Secondary Outcomes

At 12 weeks, no statistically significant between-group differences were detected for all secondary outcomes in this small pilot (Table 3). Yet, we detected a trend favoring the use of VRiKnee versus control in reducing the NRS (Cohen *d*=−0.084, *P*=.64) and WOMAC pain subscale (Cohen *d*=−0.089, *P*=.62) and improving the WOMAC stiffness subscale (Cohen *d*=−0.190, *P*=.29).

Table . Between-group differences of secondary outcomes at baseline, week 6, and week 12.

[a]VRiKnee: immersive virtual reality–assisted lower limb strength training for knee osteoarthritis.

[b]Adjusting for baseline scores: analysis of covariance and intention-to-treat analyses were used. Covariates included intervention group, gender, age, comorbidities, metabolic equivalents of task, and variable at baseline.

[c]NRS: numeric rating scale.

[d]N/A: not applicable.

[e]WOMAC: Western Ontario and McMaster Universities Osteoarthritis Index.

[f]EQ-VAS: Euro-Qol-visual analogue scale.

[g]MET: Metabolic equivalents of task.

Qualitative Outcomes

Overview

In total, 10 out of the 15 VR participants joined the qualitative interviews. Their background characteristics are summarized in Table 4. The duration of interviews lasted from 41 to 67 minutes. Further, 4 themes, 11 subthemes, and 16 quotes were generated upon analysis. The four themes included (1) embracing the use of VRiKnee, (2) facilitators of VRiKnee implementation, (3) barriers to VRiKnee adherence, and (4) suggestions for VR intervention development. The subthemes within each theme are presented in Tables 5-8.

Table . VRiKnee[a] focus group participants characteristics at baseline, week 6, and week 12.

Participant	Age (years)	Gender	Chronic diseases (n)	MET[b]	NRS[c] (score: range 0 - 10)		WOMAC-pain[d] (score: range 0 - 500)		
					Baseline	Net change	Baseline	Week 6	Week 12
1	60	Female	5	32.69	8	−5	223	115	159
2	60	Male	2	33.42	3	+4	116	168	241
3	60	Female	2	35.38	7	−4	353	296	119
4	68	Male	2	33.86	5	−3	150	66	76
5	62	Male	3	33.24	5	−1	240	118	88
6	63	Female	0	32.20	8	−1	232	275	324

[d]WOMAC-pain: Western Ontario and McMaster Universities Osteoarthritis Index pain subscale.

[e]N/A: not applicable (denotes missing data).

Table . Comparison between the quantitative and qualitative findings for embracing the use of VRiKnee[a].

Quantitative findings	Qualitative findings (subthemes)	Conclusion
Our pilot study had a 100% recruitment rate. The recruitment periods of the 3 separate batches were completed in 2 days, 6 weeks, and 1.3 weeks, respectively.	*Craving technology despite challenges*: Participants expressed their interest in VR[b] and all interviewees were positive to future use of advanced technology as a treatment modality.	Findings were complementary; VRiKnee was well-received by participants, with better exercise adherence and positive user experiences.
The participant retention rate was 87% and 93% for VRiKnee and control, respectively. The median exercise adherence for VRiKnee (77%, IQR 37%-104%) was higher than that for the control group (62%, IQR 40%-166%).	*Overcoming exercise inertia*: VRiKnee promoted a sense of achievement and satisfaction in users with exercise inertia by using gaming elements.	These findings support the above conclusions.

[a]VRiKnee: virtual reality–assisted lower limb strength training for knee osteoarthritis.

[b]VR: virtual reality.

Table . Comparison between the quantitative and qualitative findings for facilitators of VRiKnee[a] implementation.

Quantitative findings	Qualitative findings (subthemes)	Conclusion
Although this small pilot RCT[b] did not yield statistically significant results for both primary and secondary outcomes, we did observe a preliminary trend on the primary outcome of pain reduction on the NRS[c] (*P*=.64; Cohen *d*=−0.084) and WOMAC-pain[d] (*P*=.62, Cohen *d*=−0.089) at week 12.	*Improved knee osteoarthritis symptoms*: Participants who adhered to VRiKnee reported improvements in knee pain and function.	Findings were supplementary. Qualitative findings suggest that VRiKnee may offer potential benefits in managing knee osteoarthritis symptoms and enhancing exercise adherence, which might explain the observed positive, though statistically nonsignificant trends in some outcomes.
The median exercise adherence for VRiKnee (77%) was higher than control group (62%).	*Digital records enhancing exercise adherence*: Participants reported improved exercise compliance when using VRiKnee, with 5 participants noting that its record-keeping feature served as a reminder for them to exercise. Furthermore, 2 participants expressed their enhanced adherence, attributing to the competitive element of VRiKnee's virtual scoreboard.	These findings support the above conclusions.

[a]VRiKnee: immersive virtual reality–assisted lower limb strength training for knee osteoarthritis.

[b]RCT: randomized controlled trial.

[c]NRS: numeric rating scale.

[d]WOMAC-pain: Western Ontario and McMaster Universities Osteoarthritis Index pain subscale.

Table . Comparison between the quantitative and qualitative findings for potential barriers to VRiKnee[a] adherence.

Quantitative findings	Qualitative findings (subthemes)	Conclusion
Both groups had reduced exercise adherence over the 12 week period: VRiKnee group reduced from 78% to 56%, while control reduced from 69% to 48%.	*Boredom from repetition*: Our participants conveyed a sense of boredom resulting from stagnant audiovisual elements and repetitive exercise moves, which were perceived as too easy.	Findings were complementary. Quantitative results showed reduced exercise adherence with time, whereas the qualitative findings shed light on several challenges faced by participants during the VR[b] intervention. Addressing these issues is essential to enhance the overall user experience and promote better adherence to VR-based interventions in the future.
N/A[c]	*Technological challenges*: Participants suggested that the use of electronic appliances required additional time and effort. They also expressed a growing sense of frustration during prolonged use, especially when persistent technological errors were encountered.	These findings support the above conclusions.
No relevant quantitative data were available.	*Inconvenience of HMD[d] during exercise*: Participants reported that the use of HMD during exercise was inconvenient, attributing to its bulkiness when their mobile phones were installed and the sensation of feeling confined while wearing it over their eyes.	These findings support the above conclusions.
2 (13%) VR group participants reported cybersickness throughout the intervention.	*HMD-induced cybersickness*: 2 additional participants reported experiencing dizziness during the use of HMD in the focus group interviews; 1 participant reported experiencing blurred vision after prolonged use of HMD.	These findings support the above conclusions.

[b]VR: virtual reality.

[c]N/A: not available.

[d]HMD: head-mounted display.

Table . Comparison between the quantitative and qualitative findings for suggestions for VR[a] intervention development.

Quantitative findings	Qualitative findings (subthemes)	Conclusion
No relevant quantitative data were available.	*Enriching VR app's audiovisual features*: Our participants suggested to increase the variety of scenes, interactive animations, and background music in different levels, which may contribute to a more engaging and enjoyable VR experience for users.	N/A[b]
No relevant quantitative data were available.	*Enhancing VR haptic interfaces*: Our participants suggested to improve the interfaces between the VR app and the motion sensor to ensure a more accurate digital record of the exercise moves.	N/A
No relevant quantitative data were available.	*Delivering VR experiences on 2D large screens*: Half of the participants expressed a preference in performing VR-assisted exercise using large "television screens" for an enhanced VR experience.	N/A

[a]VR: virtual reality.

[b]N/A: not available.

Theme 1: Embracing the Use of VRiKnee

Overview

Participants expressed a positive reception toward the implementation of VRiKnee in their treatment, acknowledging its potential as a valuable intervention.

Craving Technology Despite Challenges

Participants expressed a strong desire to incorporate advanced technology in managing their health conditions, despite facing certain challenges with the technology. The enthusiasm toward using VR for their health needs was unanimous among all participants.

> *I really like it, actually, I am very fond of new technologies.* [P8]

Overcoming Exercise Inertia

Participants highlighted the hedonic aspects of VR, such as visual stimulation and sound effects, had played a crucial role in overcoming exercise inertia. Even novice users, who initially hesitated to engage in physical activity, reported a newfound enjoyment in the VRiKnee experience, leading to a sense of accomplishment.

> *It feels like a competition when there are consecutive exercise records in the app, having it done yesterday and today. It gives me a sense of fulfillment and a little desire to challenge myself.* [P1]

Theme 2: Facilitators of VRiKnee Implementation

Overview

Physiological improvements and enhanced exercise compliance were potential facilitators for the use of VRiKnee.

Improved Knee Osteoarthritis Symptoms

Participants reported experiencing tangible improvements in their knee osteoarthritis symptoms. The perceived benefits fostered a sense of hope and optimism, and encouraged engagement.

> *After using it (VRiKnee), I'm not sure if it's my perception, but I felt I had more strength in my legs.* [P4]

Digital Records Enhancing Exercise Adherence

Participants highlighted the role of digital exercise records provided by VRiKnee in boosting their exercise adherence. The availability of these records served as helpful reminders, encouraging them to maintain regular exercise habits and thereby improving their compliance.

> *I believe that using VRiKnee allows me to keep an exercise record. This helps me to keep a regular schedule and a more disciplined exercise habit.* [P5]

Theme 3: Potential Barriers to VRiKnee Adherence

Overview

Some barriers to VRiKnee adherence were also recognized.

Boredom From Repetition

Participants experienced declining interest and excitement in VRiKnee due to the repetitive nature of visual images and music.

> *At first, the activities seemed interesting because they provided visual motivation. After a few months, it became a bit monotonous looking at the same screen.* [P1]

> *If you do it more frequently, the first level is no longer challenging.… If I could choose, I would start from level two.* [P4]

> *VR was exciting and fresh for the first and second day, but it becomes boring after a while. So I stopped using it after a week.* [P10]

Technological Challenges

Participants faced challenges in navigating VRiKnee and operating the VR system, leading to potential frustration and reduced engagement.

> *During these past few months, most of the time was spent to deal with technology, whether the sensors were working properly or not.* [P1]

> *I wasted a lot of time in dealing with this (VRiKnee). I realized that the battery power was always not enough; I also need to deal with the machine (HMD). Sometimes my phone screen froze, and my records were all gone, so I have to start all over again from level one and two.* [P6]

> *The screen turned upside down suddenly after you succeeded a few moves. Not only that, the images also kept spinning around! Why does it have to be like this? Can't I just lift my legs on my own! I'm not interested in doing (VRiKnee) anymore.* [P7]

Inconvenience of HMD During Exercise

Participants found the HMD to be heavy and uncomfortable to wear, and eventually abandoned the use of the HMD.

> *Well, I felt that wearing the HMD on my head creates a lot of obstacles for exercising. The longer you use it, the more uncomfortable you feel.* [P10]

HMD-Induced Cybersickness

Participants generally avoided using the HMD due to experiencing cybersickness, including dizziness and blurred vision. This discomfort negatively impacted their engagement with VRiKnee exercises, leading to reduced adherence to the intervention.

> *Looking backwards with the HMD causes dizziness. You must turn around and focus on the focal point to proceed to the next step.* [P5]

> *If I use the HMD for long time and focus too much, I can't read small fonts and even the large fonts!* [P2]

Theme 4: Suggestions for VR Intervention Development

Overview

Participants offered valuable insights and suggestions for the development of VR interventions.

Enriching VR App's Audiovisual Features

Most participants expressed the need to increase the variation of scenes, interactive animations, and background music across different levels of exercise difficulty. They believe these would make VRiKnee more appealing and engaging, thereby motivating them to continue its use.

> *It would be more appealing if the images changed after each level instead of being the same all the time. Additionally, the music variety could be improved, as it was monotonous! As we progress to higher levels, incorporating more lively and upbeat music would make it more engaging.* [P10]

Enhancing VR Haptic Interfaces

Enhancing haptic interfaces would offer a more immersive and engaging experience for users, potentially increasing their motivation and adherence to the VRiKnee

> *The interface (between the app and lower limb sensor) can be less complicated! And the sensor should be able to respond accurately!* [P7]

Delivering VR Experiences on 2D Large Screens

Participants preferred to use 2D large screens which would provide a more comfortable and less intrusive experience, allowing them to engage with VRiKnee without the discomfort of wearing a HMD.

> *For us, it's hard to see with a small screen, so it's better to use a larger screen.* [P1]

Integration of Quantitative and Qualitative Findings

Quantitative and qualitative findings are integrated and displayed in Tables 5-8.

Discussion

Principal Findings

In summary, VRiKnee was well-received by participants and provided positive user experience. The qualitative analysis revealed that VRiKnee showed promising potential for managing knee osteoarthritis symptoms and improving exercise adherence, which could explain the positive trends observed in some of the quantitative outcomes. However, the quantitative results indicated a decline in exercise adherence over time. The qualitative findings highlighted various challenges faced by the participants during the VR intervention, emphasizing the need to address these issues in order to enhance the overall user experience and foster better adherence to VR-based interventions in future applications.

Comparison With Previous Studies and Implications for Research and Practice

Recently, a study conducted by Özlü et al [24] investigated the impact of disease-specific gamification through HMD on pain, physical function, and balance in participants with knee osteoarthritis. While this study population consisted of younger participants, with a mean age of 53 (SD 10.19) years, the researchers documented similar adverse effects such as cybersickness, nausea, and headache. Consequently, if immersive VR technology is to be employed in the management of knee osteoarthritis or other chronic diseases, the level of immersion must be carefully considered [56,57]. Interestingly, some participants suggested that using 2D screens may offer a more comfortable alternative, thereby prompting the exploration of the cave automatic virtual environment. This technology entails a cube-shaped room where screens project computer-generated images onto the walls, floor, and ceiling, allowing users to interact with the virtual environment via handheld controllers or trackers. Previous application of the cave automatic virtual environment system in training patients with Parkinson disease has yielded promising preliminary results [58].

Furthermore, Özlü et al [24] also observed that the beneficial effects of VR intervention diminished over time. Therefore, to sustain the positive effects of VR interventions, ensuring compliance is of utmost importance. Overcoming several obstacles during the design phase can facilitate this process. For instance, regular content updates can maintain player engagement and interest by introducing new levels, characters, game modes, or features that expand the gameplay experience. Additionally, community engagement is essential in fostering a strong player community. This can be achieved through encouraging player interaction, sharing of experiences, and providing feedback via online platforms such as forums and social media, as well as through in-game features such as leaderboards and multiplayer modes. Finally, continuous improvements based on player feedback will play a critical role in enhancing the intervention.

Strengths and Limitations

This study's strengths lie in its use of a mixed methods design, which contributes to a comprehensive understanding of VRiKnee, enhances validity through triangulation, provides valuable contextual insights, and generates practical implications on the design of future VR interventions. Further, 1 limitation of this study is the small sample size, which may restrict the trial's ability to detect meaningful effect sizes.

Conclusion

The feasibility and acceptability of VRiKnee in managing knee osteoarthritis have been demonstrated, suggesting its potential clinical efficacy. However, further confirmation through larger scale trials is necessary. VRiKnee has shown promise in enhancing exercise adherence, although a decline was observed over time. Participants faced challenges during the VR intervention, underscoring the need to address these barriers to improve adherence in future implementations.

Acknowledgments

This study was funded by the Hong Kong Jockey Club Charities Trust, under the project "CUHK-HKJC Pain Relief Projects for Seniors."

Data Availability

The data sets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

RWSS, the corresponding author, led the conceptualization, methodology, and writing of the original paper with HHML and MN, who served as the first and second authors, respectively. HHML, HHKL, and PYHF managed the project administration, while HHKL conducted the research investigation. BW, the statistician, curated the data set and performed formal analysis. Validation of results was carried out by HHML and HHKL. RWSS was responsible for the VRiKnee software development and funding acquisition or resources. The paper submission was supervised by RWSS and SYSW. The paper was then reviewed by HHML.

Abstract

Background: Adolescent mental health is of utmost importance. E-mental health interventions, and serious games in particular, are appealing to adolescents and can have beneficial effects on their mental health. A serious game aimed at improving cognitive vulnerability (ie, beliefs or attitudes), which can predispose an individual to mental health problems, can contribute to the prevention of these problems in adolescents.

Objective: This study aimed to assess the feasibility of the prototype of a serious game called "Silver."

Methods: The prototype of the serious game was developed using a user-centered participatory design. The prototype of Silver focused on 1 aspect of a serious game for improving cognitive vulnerability in adolescents, that is, the recognition and identification of cognitive distortions. Through the game, players were required to identify and classify the character's thoughts as helpful or unhelpful. Upon successful advancement to the next level, the task becomes more challenging, as players must also identify specific types of cognitive distortions. A pre- and posttest uncontrolled design was used to evaluate the game, with a 1-week intervention phase in which participants were asked to play the game. Participants aged 12-16 years were recruited in schools. The outcomes of interest were the recognition of cognitive distortions and presence of participants' cognitive distortions. The game was also evaluated on its effects, content, and usefulness.

Results: A total of 630 adolescents played Silver and completed the assessments. Adolescents were significantly better at recognizing cognitive distortions at the pretest (mean 13.09, SD 4.08) compared to the posttest (mean 13.82, SD 5.09; t_{629}=−4.00, P<.001). Furthermore, their cognitive distortions decreased significantly at the posttest (mean 38.73, SD 12.79) compared to the pretest (mean 41.43, SD 10.90; t_{629}=7.98, P<.001). Participants also indicated that the game helped them recognize cognitive distortions. Many participants considered the game appealing (294/610, 48.2%) but boring (317/610, 52%) and preferred a more comprehensive game (299/610, 49%).

Conclusions: Findings from this study suggest that a serious game may be an effective tool for improving cognitive vulnerability in adolescents. The development of such a serious game, based on the prototype, is recommended. It may be an important and innovative tool for the universal prevention of mental health problems in adolescents. Future research on the effects of the game is warranted.

Introduction

Mental illness is one of the biggest health burdens worldwide, and adolescent mental health is a particular global concern [1]. According to the United Nations' recently published report on children's mental health, approximately 1 in 7 adolescents aged between 10 and 19 years experience a diagnosed mental disorder globally [2]. Approximately 40% of these disorders are attributable to anxiety and depression [1]. The psychological distress and economic costs due to adolescent mental health problems are enormous. In 2021, the invisible economic cost due to mental health problems in adolescents was estimated at US $387 billion per year globally [2]. Moreover, these mental health problems are important risk factors for self-harm and suicide among adolescents [3,4].

Early access to treatment can improve outcomes, but limited treatment resources result in long waiting lists and undertreatment [5]. Society, and health systems in particular, need to cope with the increasingly high demands to reduce costs and prevent self-harm and suicide among adolescents. E-mental health interventions are already being used across health care and may be more accessible, engaging, and acceptable options [6-8]. These can take various forms, such as text-based programs, multimedia and interactive programs, virtual reality–based programs, and serious games [9-12]. Evidence of their beneficial effects is increasingly provided [6,13-15]. Regarding serious games, a recent review concluded that the limited evidence indicates a beneficial effect on reducing mental health problems [11,16-19]. Thus, there is a massive potential for serious games to be a new, emerging treatment modality that is more acceptable and engaging, as it uses game mechanics, especially for adolescents who are major users of computerized games in the present-day digital world. However, more research is needed [11,18,20].

This study therefore aimed at providing further evidence of the beneficial effects of serious games by piloting a prototype ("Silver") developed to counter cognitive characteristics, which are known to increase the vulnerability to common mental health problems such as depression and anxiety [21]. More specifically, the prototype targets adolescents (aged 12-16 years), aiming to gain insight into cognitive distortions (ie, negative, biased thoughts that influence people's interpretation of themselves or the world [22]) and their effect on feelings and behaviors. Cognitive distortions, including all-or-nothing thinking, overgeneralization, or mind reading, can contribute to the development of mental health issues such as depression or anxiety during adolescence [23-25]. Identifying and modifying these distortions and replacing them with more balanced, helpful thoughts—that is, cognitive restructuring—is a common technique used in cognitive behavioral therapy (CBT) [22], which has been demonstrated to prevent mental health issues during this vulnerable development phase [26,27] and improve mental well-being [28]. Given the relationship between cognitive distortions and adolescent mental health, as well as the potential of CBT-based techniques to address these distortions, this study aimed to investigate the specific impact of the prototype on adolescents' cognitive processing. Therefore, the primary hypothesis was that adolescents would improve at recognizing and categorizing helpful and unhelpful thoughts (ie, cognitive distortions) after playing Silver. Furthermore, playing the game was expected to lead to a decline in cognitive distortions. Finally, the usability of Silver was assessed, focusing on the appeal of the game.

Methods

Participants and Recruitment

Participants were aged between 12 and 16 years and had a smartphone or tablet. Participants were excluded if they were not proficient in Dutch. Recruitment took place from August 2017 to October 2017 via schools.

Ethical Considerations

School directors of 8 secondary schools with different curricula across Flanders (ie, the Dutch-speaking region in Belgium) consented to participate in the study. Parents or guardians were informed about the study and given the opportunity to decline their child's participation (opt out). Web-based assent was obtained from the adolescents before the start of the study. Participants did not receive any form of compensation for their involvement in this study. The data were deidentified prior to analysis to safeguard participants' privacy. The study was approved by the Commission for Medical Ethics of the University Hospital Ghent (Belgian registration B670201731975).

Design and Procedure

The prototype was evaluated using a pre- and posttest uncontrolled design with a 1-week intervention phase. Before participants received access to the prototype, they were asked to fill in a web-based questionnaire (pretest). Immediately after completing the questionnaire, they received access to Silver, which they were asked to play daily for 1 week. After 1 week, they were asked to fill in the second web-based questionnaire (posttest).

Intervention

The prototype of the serious game Silver aims to reduce cognitive distortions in adolescents. The prototype is based on a cognitive behavioral framework and focuses on 1 element of mental health improvement, that is, gaining insight into cognitive distortions and their effects on feelings and behaviors. The prototype was designed and developed in a cocreative manner, in which the target users themselves (ie, adolescents aged 12-16 years) were involved, as well as a clinical child psychologist, a child and adolescent psychiatrist, and professional game designers. The design, therefore, was user centered and participatory. The cocreation process was managed by the company that developed the game's prototype.

The game is set up in 3 different worlds inhabited by anthropomorphic animals. Each world has different chapters that can be played. The more a player progresses in the game, the more difficult it becomes. The game always starts with an animal that is stuck in his or her mind and therefore is in a "glitch." The incident preceding the "glitch" is explained through a flashback where the player is shown how this came about (see Figure 1). The events represent difficult situations that are very relatable for adolescents (eg, not getting likes on a social media post). Afterward, the player is shown the character's thoughts. Each time after reading a thought, the player must decide whether it is a helpful or unhelpful thought (ie, cognitive distortion). If the thoughts are correctly recognized, the unhelpful thoughts are fired upon by little robots and the helpful thoughts return to the character's head. When enough helpful thoughts have been collected, the character is released from his or her "glitch" and the chapter is completed. At higher levels, the player is also asked to indicate which type of unhelpful thought it is. At first, 2 types of cognitive distortions are introduced, that is, future thinking and all-or-nothing thinking. Afterward, 1 more type of cognitive distortion is added, that is, mind reading (see Figure 2). Thus, the further you progress through the game, the more difficult it becomes as the thoughts can be categorized into more types of cognitive distortions. In this way, the player learns to gain insight into the different types of cognitive distortions.

Figure 1. Screenshot of Silver, showing a flashback to the incident before the glitch. “Maar vanochtend stak zijn moeder nog een kakelvers woestijnvosje in zijn lunchbox.” means “But this morning, his mother stuck another brand-new desert fox in his lunch box.”

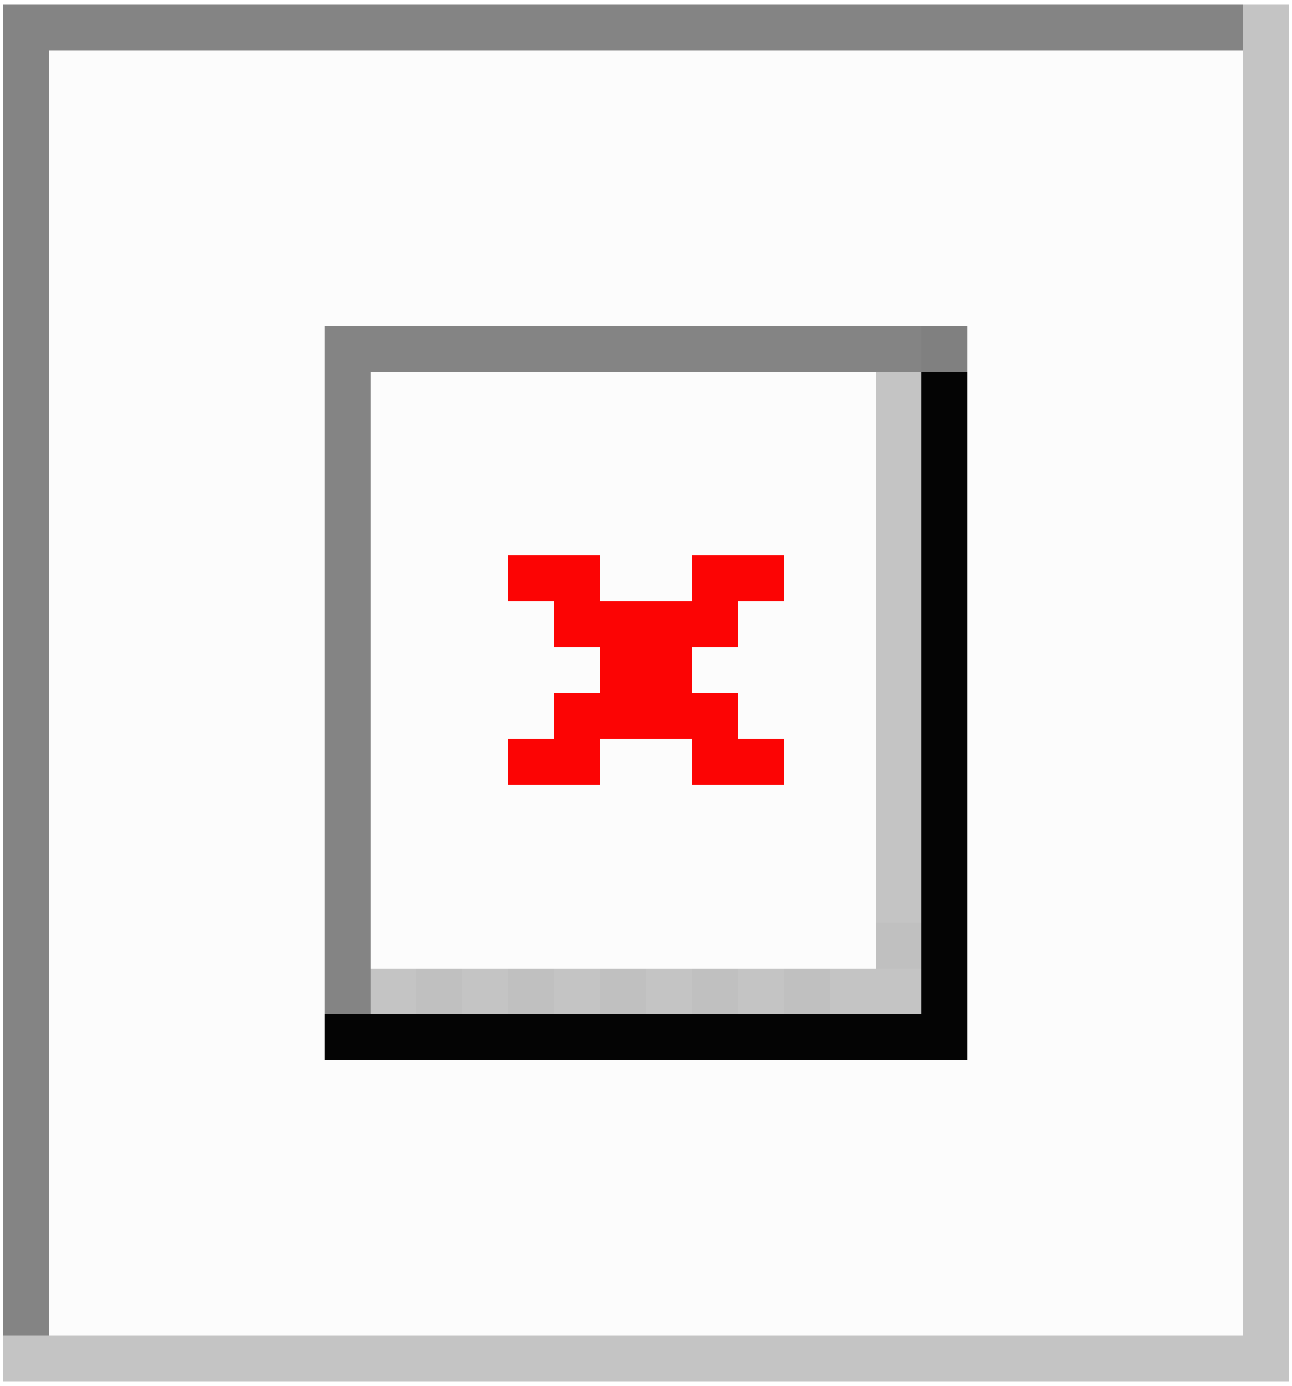

Figure 2. Screenshot of Silver, showing the process of identifying types of cognitive distortions. “Aan tafel zijn ze al zeker met mij aan het lachen.” means “At the table, they are already definitely laughing at me.“; “Helpend” means “Helpful”; “Toekomst” means ”Future”; “Gedachten lezen” means “Read minds”; and “Zwart-wit” means “Black and white.”

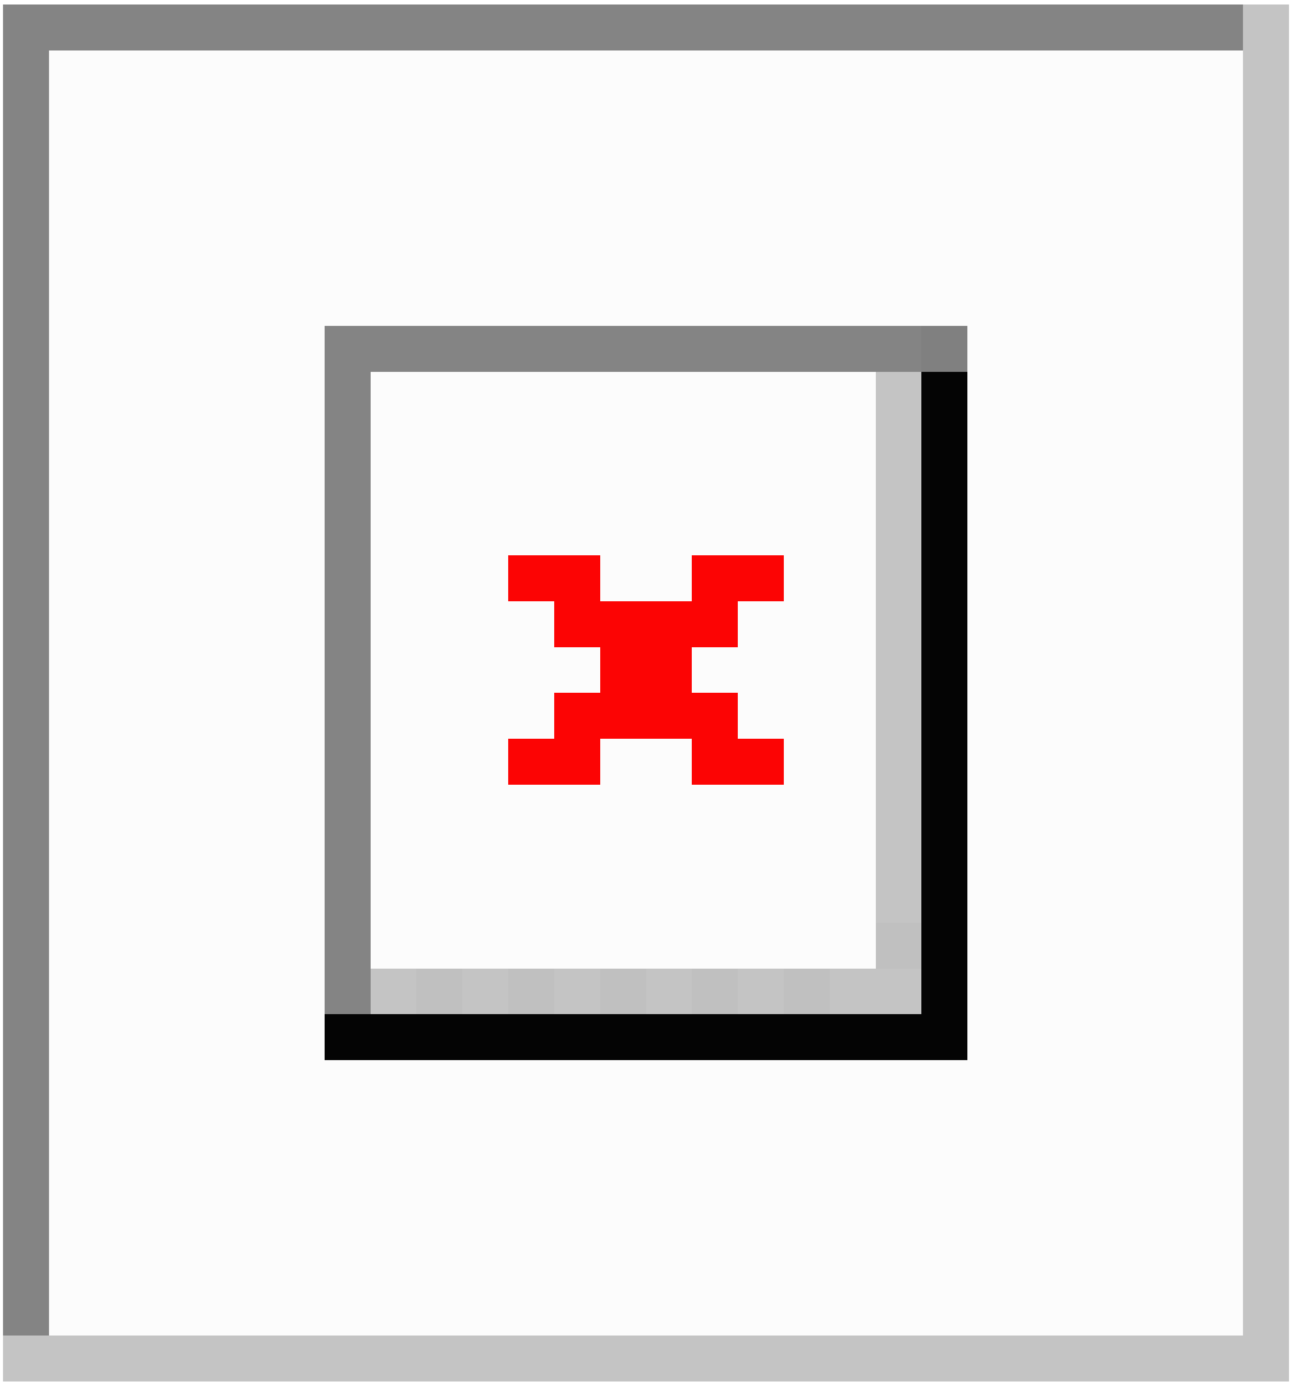

Measures

All outcome measures were collected via self-report questionnaires, which were administered on the web.

Demographics

Sociodemographic information (ie, gender, age, and education) was assessed at the pretest. Data on sex (male, female, or other), age (in years), and education (first or second grade and type of curriculum, ie, general secondary education, technical secondary education, secondary education in the arts, and vocational education) were obtained. In addition, participants were asked if they had ever been in therapy for psychological problems.

Media and Game Use

At baseline, data were collected regarding participants’ use of media by asking participants what type of media they used and how often they used it on a 5-point scale (1=“never”; 5=“daily”). Items regarding game use assessed whether they ever played computer or video games and whether they still played them. Furthermore, participants were asked on which devices they played the games and how often they did this on a 5-point scale (1=“never”; 5=“daily”). They also gave an estimate about their knowledge about games, ranging from 1= “no knowledge” to 4=“expert.”

Primary Outcome Measure: Recognition of Negative and Positive Automatic Thoughts

The primary outcome measure focused on recognizing helpful and unhelpful thoughts. A questionnaire was developed, in which 20 items of the Dysfunctional Attitude Scale, Form A, Dutch translation [29,30] were used. Participants were asked to classify each item as helpful, unhelpful, or "I do not know." Items were scored as true or false. Scores ranged from 0 to 20, with higher scores indicating a better identification of negative and positive automatic thoughts. The internal consistency of the scale in this study was α=.82.

Secondary Outcome Measure: Presence of Cognitive Distortions

The Children's Negative Cognitive Error Questionnaire–Revised [31] is a 16-item self-report questionnaire that assesses cognitive distortions in those aged 9-17 years. The questionnaire consists of 5 subscales that measure 5 categories of cognitive distortions: "underestimation of the ability to cope," "personalizing without mind reading," "mind reading," "selective abstraction," and "overgeneralizing." In each item, a situation is described, followed by a possible thought about the situation. Participants are asked to rate on a 5-point Likert scale how much the thought corresponds to what they would think in that situation, ranging from "almost exactly like I would think" (5 points) to "not at all like I would think" (1 point). Total scores range from 16 to 80, with a higher score reflecting more distorted cognitive errors. The total scale has a good level of internal consistency and good test-retest reliability [31,32].

Game Evaluation

At the posttest, participants were asked to rate various statements regarding the effects, content, and usefulness of the game. Items were rated on a 5-point Likert scale (1="completely disagree"; 5="completely agree"). An example of an item is "By playing the game I will be able to recognize my own cognitive distortions." Participants were also asked how they would rate the game overall on a scale from 0 to 10.

Statistical Analysis

Power and sample size could not be based on previous studies due to a lack of comparable studies. An effect size of 0.3 was assumed. To detect such an effect size with α=.05 and β=.80, a total sample of 500 participants was calculated. However, since a possible high dropout of 70% to 75% was expected [33], the total required sample size was estimated at 1753.

Differences between the participants of the study and those who dropped out during the study, as well as differences between those who played the game (ie, gamers) and those who did not play it (ie, nongamers), were examined with χ^2 tests (for categorical variables) and 2-tailed independent-sample *t* tests (for continuous variables). Mean changes between the pre- and posttests were carried out using 2-tailed paired-samples *t* tests. The corresponding effect sizes were assessed using Cohen *d*. A significance level of .05 was used for all outcome analyses. All data were analyzed using SPSS software (version 27; IBM Corp).

Results

Sociodemographic Characteristics and Baseline Outcome Measure

A total of 1654 adolescents signed up to take part in the study. Among these, 1140 took part in the pre- and posttests. Table 1 presents the differences between the participants who completed both the pre- and posttests and those who only completed the pretest.

Table . Sociodemographic characteristics and baseline outcome measures of participants who completed both the pre- and posttests and participants who only completed the pretest.

Characteristics		Pre- and posttests (n=1140)	Pretest only (n=514)	*P* value
Sex, n (%)				
	Female	700 (61.4)	303 (58.9)	.34

[e]CNCEQ-R: Children's Negative Cognitive Error Questionnaire–Revised.

Of the 1140 adolescents who completed the pre- and posttests, 510 (44.7%) reported that they did not engage with the game (hereafter referred to as nongamers). The primary reason for nonengagement was technical problems (233/510, 45.7%) such as inability to download the game. Other reasons included a lack of time or forgetfulness (198/510, 38.8%), a disinterest in the game (51/510, 10%), and other unspecified reasons (59/510, 5.5%). In contrast, 630 (55.3%) of the 1140 adolescents indicated that they played the game (hereafter referred to as gamers). There were no significant differences in all baseline sociodemographic characteristics between gamers and nongamers except for type of education curriculum (P=.02; see Table 2). Additionally, adolescents who played the game scored significantly higher on recognizing automatic thoughts (mean 13.09, SD 4.08 vs mean 12.08, SD 4.65; t_{1020}=–3.86, P<.001) and significantly higher on the Children's Negative Cognitive Error Questionnaire–Revised (mean 41.43, SD 10.90 vs mean 40.05, SD 11.01; t_{1138}=–2.10, P=.04) at baseline (see Table 2).

Table . Sociodemographic characteristics and baseline outcome measures of gamers and nongamers in schools.

Characteristics		Gamers (n=630)	Nongamers (n=510)	*P* value
Sex, n (%)				
	Female	371 (58.9)	329 (64.5)	.053
	Male	251 (39.8)	178 (34.9)	.09
	Other	8 (1.3)	3 (0.6)	.24
Age (y), mean (SD)		13.43 (1.30)	13.36 (1.33)	.40
Education curriculum, n (%)				
	First-grade GSE[a]	186 (29.5)	120 (23.5)	.02
	First-grade VE[b]	25 (4)	30 (5.9)	.13
	Second-grade GSE	264 (41.9)	249 (48.8)	.02
	Second-grade TSE[c]	99 (15.7)	74 (14.5)	.57
	Second-grade SEA[d]	14 (2.2)	6 (1.2)	.18
	Second-grade VE	42 (6.7)	31 (6.1)	.69
Treatment for psychological problems, n (%)				
	Never been to therapy	542 (86)	442 (86.7)	.76
	More than a year ago	39 (6.2)	29 (5.7)	.72
	Less than a year ago	31 (4.9)	19 (3.7)	.33
	In therapy	18 (2.9)	20 (3.9)	.32
Baseline outcome measures, mean (SD)				
	Recognizing automatic thoughts	13.09 (4.08)	12.08 (4.65)	<.001
	CNCEQ-R[e]	41.43 (10.90)	40.05 (11.01)	.04

[a]GSE: general secondary education.
[b]VE: vocational education.
[c]TSE: technical secondary education.
[d]SEA: secondary education in the arts.
[e]CNCEQ-R: Children's Negative Cognitive Error Questionnaire–Revised.

Media and Game Use

Table 3 shows media and game use of the gamers versus the nongamers. The nongamers were significantly less likely to play games currently (270/510, 52.9% vs 405/630, 64.3%; χ^2_1=15.02, *P*<.001) and were significantly more likely to have "no knowledge" about games than the gamers (69/510, 13.5% vs 54/630, 8.6%; χ^2_1=7.20, *P*=.007).

Table . Media and game use of gamers and nongamers in schools.

Media and game use		Gamers (n=630)	Nongamers (n=510)	*P* value
Media use, n (%)				
	Smartphone use	615 (97.6)	496 (97.3)	.70
	Tablet use	466 (74)	360 (70.6)	.20
	Desktop use	226 (35.9)	179 (35.1)	.79
	Laptop use	501 (79.5)	409 (80.2)	.78
	Game console use	367 (58.3)	279 (54.7)	.23
Game playing, n (%)				
	Ever	601 (95.4)	476 (93.3)	.13
	Currently	405 (64.3)	270 (52.9)	<.001
Game knowledge, n (%)				
	No knowledge	54 (8.6)	69 (13.5)	.007
	Beginner	260 (41.3)	211 (41.4)	.97
	Advanced	255 (40.5)	198 (38.8)	.57
	Expert	61 (9.7)	32 (6.3)	.04

Outcome Measures

Table 4 shows the mean changes in the outcome measures from pre- to posttest and its effect sizes for the group that played the game. The gamers significantly improved in recognizing automatic thoughts (*P*<.001) and had significantly fewer distorted cognitive errors (*P*<.001). On both measures, the difference represented a small effect size (0.16 and 0.23, respectively).

Table . Pre- and posttest scores on outcome measures and 2-tailed paired *t* test results.

Outcome measures	Pretest score, mean (SD)	Posttest score, mean (SD)	*t* test (*df*)	*d* (95% CI)	*P* value
Recognizing automatic thoughts	13.09 (4.08)	13.82 (5.09)	−4.00 (629)	0.16 (−1.09 to −0.37)	<.001
CNCEQ-R[a]	41.43 (10.90)	38.73 (12.79)	7.98 (629)	0.23 (3.36 to 7.98)	<.001

[a]CNCEQ-R: Children’s Negative Cognitive Error Questionnaire–Revised.

Game Evaluation

A total of 610 gamers gave a score on the various evaluation items (see Table 5). Besides the high number of neutral responses, they generally moderately or highly agreed with the items. The median overall satisfaction rating of 599 gamers, which was scored on a scale of 1 to 10, was 6 and the mean was 5.51 (SD 2.30).

Table . Game evaluation ratings (n=610).

Statements	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Score, mean (SD)
By playing the game I learned about different ways of thinking.	134 (22)	278 (45.6)	198 (32.5)	2.10 (0.73)
By playing the game I will recognize my unhelpful thoughts.	123 (20.2)	244 (40)	243 (39.8)	2.20 (0.75)
The game helps me to reflect more upon my thoughts.	164 (26.9)	272 (44.6)	174 (28.5)	2.02 (0.75)
I can empathize with the stories in the game.	202 (33.1)	204 (33.4)	204 (33.4)	2.00 (0.82)
I think the game is beautifully made.	96 (15.7)	220 (36.1)	294 (48.2)	2.32 (0.73)
I find the game difficult.	283 (46.4)	198 (32.5)	129 (21.1)	1.75 (0.78)
I find the game boring.	122 (20)	171 (28)	317 (52)	2.32 (0.79)
I would like it if the game was not only about thoughts but also about feelings and relaxation.	102 (16.7)	209 (34.3)	299 (49)	2.32 (0.74)

Discussion

Principal Findings

The aim of this pilot study was to test the efficacy and usability of the prototype of Silver, a serious game aimed at reducing cognitive distortions in adolescents and thus decreasing cognitive vulnerability to mental health problems. The trial supports our hypothesis that automatic thoughts are better recognized after playing Silver. This enhancement in cognitive awareness was also reflected in the evaluation of the game, wherein gamers indicate that playing the game helps in recognizing unhelpful thoughts. Furthermore, after having played the game, adolescents showed fewer cognitive distortions than before playing. These findings are in line with prior studies, underscoring the positive impact of serious games on cognitive beliefs and modification [19,34-37]. This study contributes to the growing evidence on digital interventions that incorporate core components of CBT, such as cognitive restructuring, and their beneficial effects on well-being and mental health issues [38]. Silver's emphasis on identifying and mitigating cognitive distortions aligns closely with the principles of rational emotive behavior therapy (REBT), a type of CBT [39]. This therapeutic approach focuses on the identification, challenge, and substitution of irrational beliefs with rational counterparts, alongside learning to manage emotions and behavior in a more helpful way. Literature suggests that serious games focusing on REBT techniques seem to have a strong positive effect in mitigating symptoms of depression and anxiety [19]. Considering the significant outcomes associated with the current version of Silver, which primarily targets cognitive distortions, an expanded version of the game that includes elements intended to address emotional and behavioral aspects could potentially have a greater positive impact on mental health. The inclusion of these additional components could further enhance the game's therapeutic effectiveness, aligning with REBT's approach to mental health improvement [19].

Regarding the evaluation of Silver, the majority (294/610, 48.2%) of gamers indicated that Silver is appealing. Research has shown that nonappealing interfaces may be off-putting and may cause adolescents to disengage from the game. The cocreation of Silver with the target audience probably has ensured that it has attractive aesthetics [40]. In contrast, the majority (317/610, 52%) also perceived Silver as boring. Adolescents may experience serious games in such a manner since they often have very didactic content that does not match commercial, off-the-shelf games, and as a result, the adolescents may cease playing these games [40]. This dichotomy can be attributed to the prototype's focus on a single aspect of cognitive vulnerability (ie, cognitive distortions), which, although important, may lack the variety necessary to sustain players' interest over time. Therefore, this may be a critical area for further development in diversifying the game's content and mechanics. The game could be broadened to include a range of elements. This could mitigate the issue of monotony, thereby improving overall engagement and effectiveness [19]. Furthermore, the gamers indicated that they would like a more comprehensive game that also deals with feelings and relaxation. Such a game may be more eventful, more fascinating, and less boring.

Preceding a discussion of potential implications of the study findings for the development of serious games, methodological issues need to be addressed. First, as this was a pre- and posttest study, a control group was lacking. Therefore, we were unable to compare the effects on the gamers with those in a random control group that did not play the game. A convenience sample was used, which can lead to a selection bias and consequently underrepresent or overrepresent particular groups. Efforts were made to counter this as much as possible by recruiting a large number of adolescents from 8 different schools with various curricula. However, it is also unclear why some adolescents agreed to take part in the study but others did not. As the sample was not chosen at random, the inherent bias in convenience sampling means that any generalizations of findings must be made with caution. Second, a large group did not adhere to the study protocol. The main reason for dropout were technical difficulties. These were largely due to the prototypic nature of our app; as it was not readily available on app stores, it required adolescents to undertake multiple steps before receiving access to the game. Moreover, participants' feedback showed time constraints and forgetfulness as additional factors for not engaging with the game. To mitigate these issues in future studies, it is imperative to streamline the app's accessibility, potentially by securing its availability on common digital distribution platforms. Furthermore, incorporating human support may serve to enhance participant engagement and possibly the overall effectiveness of the intervention [41]. Addressing these aspects is critical for improving study adherence and ensuring the robust evaluation of the app's therapeutic potential. Furthermore, participants who dropped out were older and had a lower education level. Additionally, they may have experienced more mental health problems, as baseline measurements showed that they were less skilled at recognizing automatic thoughts and were currently more likely to be in treatment for psychological problems. The nongamer group encompassed more adolescents with little interest in games, as they currently played no games or had less knowledge about them. In addition, they were less skilled at recognizing automatic thoughts but had fewer cognitive distortions themselves. However, high attrition rates are not uncommon when studying e-mental health interventions. A systematic review and meta-analysis of computer-based psychological treatments showed an overall dropout rate of 57%, which further increased to 74% in unsupported digital programs [6,42]. In this study, the adolescents were also not offered any support, and this may have had a major effect on adherence. Adding human support could decrease the attrition rate and may even increase the effectiveness of the serious game [43,44]. Moreover, the effectiveness of serious games is often assessed in pragmatic study trials. The real-life settings in which these studies are carried out can also have an impact on the attrition rate. Nevertheless, this type of study can improve the generalizability of the results, as the environments in which they will be implemented are similar to the ones in the trials [45]. Third, no standardized questionnaire for the recognition of automatic thoughts was used. The questionnaire was based on an existing standardized questionnaire [29,30] but was adapted for this study. Fourth, participants often responded with "neutral" in the game evaluation. Although they may have used the neutral midpoint response because they did not comprehend the items or were undecided, offering these neutral responses may decrease the quality and reliability of a questionnaire, particularly in adolescents, since they are more sensitive to pleasing by selecting a neutral answer. Future studies should consider omitting the neutral midpoint [46,47]. Fifth, the study's emphasis on quantitative measures may have introduced acquiescence bias. Adding qualitative methodologies may provide a more nuanced perspective of the participants' experiences with the prototype. Future studies should consider using a mixed methods approach to enhance understanding of the intervention's impact [48].

Lastly, the eligibility criterion requiring participants to possess a smartphone or tablet may have introduced a selection bias, potentially excluding adolescents without access to such technology or those reluctant to use it. This could inadvertently reinforce the digital divide, that is, inequalities in accessing and using information and communication technologies [49], and limit the generalizability of the findings. Future research should address this limitation by using more inclusive recruitment strategies to minimize technological barriers and ensure broader participation.

It is difficult to assess the effect of these methodological issues on the validity of the current findings, more so as the current results are difficult to compare to those from similar previous studies. The few available studies of serious games aimed at cognitive training had targeted adults or children with particular mental health problems such as anxiety, alcohol use disorder, or attention-deficit/hyperactivity disorder [11,20]. To the best of the authors' knowledge, only 2 serious games were studied regarding effects on emotional resilience or mental health promotion in a community sample of adolescents. The results of these studies are comparable to our findings [20,35,36].

Conclusions

In conclusion, and keeping the limitations mentioned above in mind, this pilot study demonstrates the promising effects of the Silver prototype. Notably, participants exhibited not only an enhanced ability to recognize cognitive distortions but also a significant decrease in their own experiences of such distortions after engaging with the prototype. This observation suggests a potential positive influence on cognitive characteristics, which are commonly associated with mental health issues. It is therefore recommended that a serious game aimed at decreasing cognitive vulnerability and therefore improving mental health in a general population of adolescents should be developed further and that its efficacy should be studied in future research. This study provides a few cues for further research. The dropout of adolescents who may have the greatest need for cognitive restructuring is a matter of concern, and reasons and remedies for this worrisome issue should be targeted in future research. Randomized controlled trials should be used to further explore the effects of serious games on adolescents in the general population, preferably using an active control group that engages with a different type of digital intervention [50]. Follow-up periods should be sufficiently long to study potential preventative effects among adolescents (Reynard et al [20]).

Acknowledgments

Funding for this study was provided by the Flemish government. We are very grateful to the participants, teachers, school directors, and game company whose time and efforts made this work possible.

Abstract

Background: Approximately half of smokers attempt to quit, but 90% of these attempts fail. Video game–based interventions have the potential to address common barriers to evidence-based smoking cessation treatment, including high cost, lack of health care access, and low engagement.

Objective: The purpose of this study was to evaluate the feasibility and acceptability of a video game–based smoking cessation intervention called Inspired and its impact on the 7-day smoking point prevalence at the 30-day follow-up.

Methods: US adults (n=48) were recruited via the web to use Inspired on their smartphones for 7 weeks. The object of the game was to defend a healing tree against attackers. Levels of the game were unlocked twice daily when participants self-reported the number of cigarettes they smoked since the previous entry. Completion of the levels awarded players in-game currency, which could strengthen in-game abilities. Participants received additional in-game rewards to aid gameplay by submitting either smoking self-reports only or self-reports indicating abstinence, determined through random assignment. In addition, participants completed a web-based survey at intake, week 4, week 7, and the 30-day follow-up.

Results: Of the 48 participants, who had an average age of 39.8 (SD 10.7) years, 27 (56%) were female, 4 (8%) Hispanic, 37 (77%) White, and 27 (56%) employed; 26 (54%) earned <US $40,000 a year; and 14 (29%) lived in nonurban areas (eg, rural and suburban). There were no significant differences between the groups, so all outcome data were combined. Participants averaged 20.6 (SD 15.3) days of gameplay and reached a mean highest game level of 10.7 (SD 8.4), although there was a high degree of variability. Participants reported abstinence on 31.4% (SD 38.2%) of all cessation phase reports and averaged 5.4 (SD 9.8) consecutive abstinent smoke reports. For every 1 SD increase in the highest level achieved, there was a 27% increase in the percentage of abstinent samples and a 405% increase in longest continuous abstinence. At the 30-day follow-up, 23% (11/48) of the participants reported having not taken a cigarette puff in the prior 7 days and 31% (15/48) had spent at least 24 hours without smoking in the prior 14 days. On an 11-point scale, participants rated the intervention moderately favorably: if they had to do it again, they would use Inspired to help them quit (mean 6.4, SD 3.4), and Inspired was helpful in their current attempt to quit (mean 5.4, SD 3.6).

Conclusions: These results support the acceptability of Inspired. Although high dropout rates prevent conclusions on feasibility, a subset of the participants responded favorably. Scalable and accessible video game–based smoking cessation interventions could be the key to addressing the foremost cause of preventable morbidity and mortality in the United States.

Introduction

Background

Although the prevalence of smoking has steadily declined over the past several years, cigarette smoking remains the foremost cause of preventable morbidity and mortality in the United States, accounting for approximately 480,000 deaths each year [1]. Most smokers express an interest in quitting, and approximately half of smokers attempt to quit; however, approximately 90% of quit attempts fail [2]. Evidence-based interventions such as cognitive behavioral therapy and pharmacotherapy are most likely to result in smoking cessation; however, only 31% of smokers used counseling or medication in their quit attempt, and fewer still used these strategies if they were of low socioeconomic status [2-4]. Therefore, the development of effective interventions must include efforts to optimize their accessibility and appeal to all smokers who wish to quit.

Mobile health phone apps have substantially greater reach than in-person health visits and may reach populations of smokers who wish to quit but would not otherwise access in-person smoking cessation assistance. Mobile apps hold promise in their flexibility, patient-directed treatment options, and the ability to reach individuals who are not comfortable discussing smoking cessation with a health care professional. These apps vary widely in their level of interactivity, and participant retention remains low [5,6]. Attempts to increase app use have included gamification (ie, applying game-like elements without the context of an actual game) such as goal setting, progress tracking, and earning markers such as badges [7]. Use of these features has been associated with increased motivation to quit [8], but efforts to increase subjective enjoyment of the interventions may further expand their use.

One approach that may increase subjective enjoyment while maintaining accessibility is the use of video game–based smoking cessation interventions, the main component of which consists of a playable game [9-17]. In the United States, approximately 62% of adults report playing video games, and 75% of players spend ≥3 hours playing games per week [17]. One survey conducted among smokers indicated that 75% of participants already played video games, and 65% to 67% of participants believed that a video game–based smoking cessation intervention could help them or someone they knew quit smoking [18]. With 64% of video game players in the United States reporting the use of their smartphone to play games [19], smartphones provide an accessible platform on which to develop an intervention that is scalable, acceptable, and enjoyable.

Multiple video game–based smartphone smoking cessation interventions have been developed and tested, including Inner Dragon [16], Cigbreak [17], Tobstopp [12], QuitIt [15], and Quittr [13]. A recent review examined other smoking intervention games, highlighting 7 studies that featured digital cessation games. These games drew on a range of theories including social cognitive theory and cognitive behavioral therapy, and they had a wide variety of game features including earning points and other rewards as well as interactive storytelling. Results were mixed, with approximately half of the studies achieving significant effects on either the smoking status or the number of cigarettes smoked, and most studies displayed high rates of dropout [14].

In an attempt to improve cessation outcomes seen in video game–based smartphone interventions, we previously developed and evaluated a prototype of a stand-alone video game called Inspired [9]. Inspired was unique because it drew from the science of contingency management, which is a powerful intervention consisting of delivering incentives when individuals meet operationally defined and objectively verified behavioral goals [20]. One common criticism of contingency management is the cost of these typically monetary incentives, so Inspired used in-game rewards whose only value was in the context of the game [21,22]. The original intention of the game was to reward users for providing objective evidence in the form of breath carbon monoxide (CO) for meeting abstinence goals, with the goal that this would function as a positive reinforcer for smoking abstinence [23]. Adult smokers recruited via the web (N=28) viewed the prototype favorably and indicated that they thought a fully developed version of the game had the potential to be fun (100%) and help them quit smoking (71%). Participants also provided feedback for improving the gameplay, such as adding variation to game levels to reduce monotony and adding narrative to engage the player.

To continue this work, a beta version of Inspired was designed and developed by an interdisciplinary team of researchers and game designers based on the prototype evaluation. The narrative of the game explained that the players were tasked with saving a village and its people from invading enemies known as "creatures of darkness." At each level of the game, players needed to build defensive structures to protect a healing tree from the creatures. Game design elements included a core game system (ie, levels where the creatures were battled and earnings could be obtained), a metasystem (ie, where earnings could be spent to customize villages and upgrade structures), and a smoking cessation program in which players could earn in-game rewards for complying with the smoking cessation program's objectives.

Objectives

The original aim of the study was to examine the impact of in-game rewards dependent on objectively verified smoking abstinence on the 7-day smoking point prevalence at the 30-day follow-up. However, this objective was shifted due to technical difficulties with objective verification measures and insufficient impact of abstinence-dependent rewards (explained in the Methods section). Therefore, the purpose of this study was to evaluate the feasibility and acceptability of the beta version of

Inspired as a smartphone-based smoking cessation intervention to inform future research on smoking cessation games. The main outcome remained the 7-day smoking point prevalence at the 30-day follow-up; secondary outcomes included the longest self-reported abstinence streak and percentage of abstinent self-reported submissions during the abstinence phase.

Methods

Ethics Approval

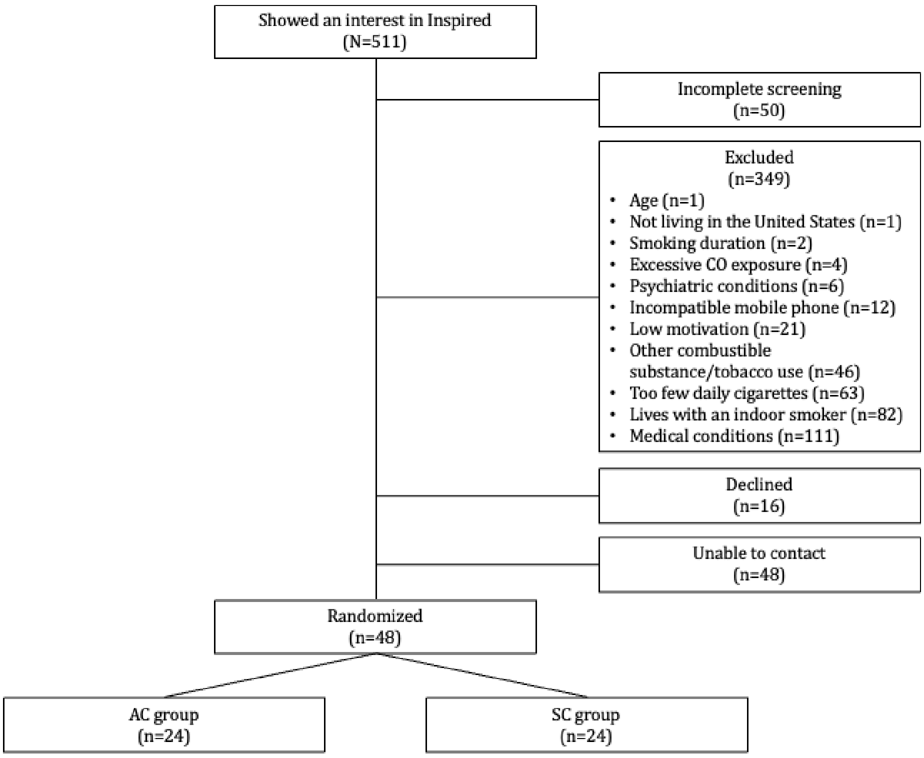
All procedures were reviewed and approved by the Rowan University Institutional Review Board (IRB-2014-170).

Participants

Participants were recruited on the web through Craigslist, Facebook (Meta Platforms, Inc), Google Ads (Google LLC), and Mechanical Turk (MTurk, Amazon). Multiple advertisements with similar but varying text (eg, "test out a mobile video game designed to help you quit"), images (eg, a screenshot of gameplay), and a link to a screening survey were included. The study was submitted to ClinicalTrials.gov on September 26, 2017, and was published on the website on April 24, 2019. Participants were recruited between May 3, 2019, and July 25, 2019. The screening survey was used to obtain information on age, smoking history, desire to quit, prior experience with video games, access to mobile devices, and contact information (refer to the study by Upton et al [11] for a secondary analysis of the screening data). Inclusion criteria required participants to (1) be of legal age to purchase cigarettes in their state or jurisdiction, (2) smoke ≥10 cigarettes per day, (3) report smoking for at least 2 years, (4) report a desire to quit of ≥8 on a 10-point Likert scale, and (5) own a smartphone using the Android operating system and have an active data plan or access to Wi-Fi to connect to the internet. Exclusion criteria were (1) smoking cannabis or using other tobacco products >2 times per month, (2) having unstable medical or psychiatric conditions that may interfere with submitting accurate CO samples (eg, asthma and lactose intolerance), and (3) living with someone who smokes in the house and (4) having a career that results in excessive exposure to CO (both of which would interfere with CO sample accuracy). Respondents were also asked whether they played video games and the types of games they played. If respondents reported that they did not play games, the researcher followed up by asking whether they were interested in playing a game designed to help them quit smoking.

A total of 511 respondents completed the screening survey, of whom 113 (22.1%) met the inclusion criteria. Respondents who met the inclusion criteria were contacted by email or phone so that study staff could explain additional information about the study and the individual could be fully informed before deciding to participate. A total of 48 participants were enrolled (see Figure 1 for a CONSORT [Consolidated Standards of Reporting Trials] diagram). Analyses were conducted in SPSS (IBM Corp) and R software (R Foundation for Statistical Computing).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram. AC: abstinence contingent; CO: carbon monoxide; SC: submission contingent.



The original recruitment goal was 114 participants based on a power analysis using an α level of .05 and an anticipated odds ratio of 6.68 to achieve 80% power when analyzing the effect of group on the dichotomous 7-day smoking point prevalence. However, due to considerable technical difficulties with collecting objective measures of smoking, recruitment was delayed, and a final sample of 48 participants was achieved. Initially, participants were required to submit breath CO samples to verify smoking abstinence within the last 12 hours or more using a portable breath CO detector (iCO) [24], which was attached to the participant's phone via the headphone jack. Furthermore, to verify the identity of the participant submitting the CO sample and subsequent smoking self-report, participants were required to use facial recognition software that was built into the game. Due to technical difficulties with the vendor-supplied hardware and software, both breath CO monitoring and facial recognition technologies were removed from the procedures after a pilot trial of participants. We transitioned to relying exclusively on smoking self-reports to determine smoking status for the purposes of in-game rewards, which is the standard practice for most app-based smoking cessation trials [25]. It should be noted that the final analytical sample comprised participants who exclusively reported their smoking through self-report as opposed to CO monitoring.

Participants completed the psychosocial history questionnaire at intake, which included questions about demographic information, smoking history, and cessation history. Questions on smoking and cessation history included current tobacco use patterns (eg, the number of cigarettes smoked per day and use of other tobacco products), smoking onset (eg, age at which the first cigarette was smoked and age at which the participants started smoking daily), and quitting behavior (eg, number of previous quit attempts). Participants rated how much they wanted to quit smoking on an 11-point scale (0-10), with higher ratings representing a greater desire to quit.

Participants completed the Fagerström Test for Nicotine Dependence during intake, which consisted of 6 items. The total score summed the responses and represented the participant's current level of cigarette dependence. A total score of 1 to 2 indicated low dependence, 3 to 4 indicated low to moderate dependence, 5 to 7 indicated moderate dependence, and ≥8 indicated high dependence [26].

The Video Game Use Survey is a 19-item measure that was administered during intake [18]. Questions assessed game playing history (eg, duration played per week) and preference for games (eg, action and adventure; strategy and puzzle) in an open-ended response format.

Study Phases

The game was designed for 7 weeks of gameplay. Participants completed web-based survey assessments at intake, week 4, week 7, and the 30-day follow-up. Assessment content included psychosocial history, video game use, and perceptions of the intervention. Data from intake, week 7, and the 30-day follow-up were used in these analyses. Survey links were sent via email, and compensation was loaded after response completion was confirmed. Participants were mailed debit cards (CT Payer), through which compensation was delivered after completion of each battery of surveys (ie, setup: US $10, week 4: US $15, week 7: US $20, and 30-day follow-up: US $30). The compensation provided for survey completion was not connected to participant cessation efforts. Each participant was told they had the opportunity to earn a total of US $75 in compensation if all surveys were completed, regardless of whether they quit smoking.

During intake, the researcher walked each participant through downloading the Inspired app and submitting their first smoking self-report. Smoking reports, explained in more detail in the Smoking Self-Report in the Methods section, consisted of reporting the number of cigarettes smoked since the last report. Participants had the opportunity to submit 2 reports a day, waiting at least 8 hours between reports.

In the baseline phase (days 1 to 3), all participants received in-game rewards (detailed in the Gameplay section) for submitting each smoking self-report and a silver multiplier for every 3 consecutive smoking self-report submissions; however, participants were not given any smoking goals. After baseline, graduated smoking reduction and cessation goals for the remainder of the study were provided to all participants. During the tapering phase (days 4 to 7), participants were given decreasing daily target smoking caps, calculated based on the mean number of cigarettes reported during baseline, such that the final goal of the tapering phase would be 0 (eg, mean 20 cigarettes divided by 8=goal reduced by approximately 2 to 3 cigarettes per required smoke report). During the abstinence phase (weeks 2 to 4) and thinning phase (weeks 5 to 7), smoking goals were always set to 0. Initially, the schedule of rewards was programmed to end in the thinning phase. A thinning phase is common in reinforcement-based interventions and consists of gradually reducing the frequency of reinforcer delivery to reduce dependence on the reinforcer while maintaining high rates of the target behavior. This helps an individual transition to maintaining abstinence, even when the reinforcer is no longer available [27]. However, due to low rates of engagement in the thinning phase, participants received rewards at the same frequency as the abstinence phase until the end of the thinning phase.

A repeated measures group design was used. Upon enrollment, participants were randomly assigned to either a submission contingent (SC) or an abstinence contingent (AC) experimental group. All participants were given goals for smoking reduction and eventual abstinence. The SC group earned "passes" for submitting smoking self-reports on schedule, regardless of whether they reported meeting their assigned smoking reduction or abstinence goals. The AC group earned "passes" only for submitting self-reports that met their assigned smoking reduction or abstinence goals. Submissions reporting cigarette use that did not meet their smoking reduction or abstinence target were scored as a miss. For both SC and AC groups, failure to submit a self-report by the reporting deadline was scored as a miss. Thus, the only difference between the SC and AC groups was what qualified as "passing" to earn the in-game rewards. The groups were designed to compare the impact of in-game reinforcement on cessation efforts and to determine if requiring abstinence to receive rewards would be more effective than the act of reporting smoking behaviors alone, as we have done with monetary-based contingency management [28,29]. We hypothesized that the group that received in-game rewards for their abstinence would be more likely to quit smoking than the group that received in-game rewards for submitting their smoke reports only.

We compared the SC and the AC groups at intake to detect systematic group differences based on reported demographics, smoking history, cessation history, nicotine dependence, and game playing history. The 2 groups were also compared on the proportion of participants completing baseline, tapering, abstinence, and thinning phases to determine differences in dropouts.

Gameplay

Each level in the core game began with planting a seed to grow a new healing tree. Players needed to repeatedly build and activate defensive structures to fight incoming enemies and to activate healing structures to help the tree grow. At the start of each level, players were given a bank of gems, which varied in color and shape. Players could choose to activate either a defensive or healing structure for a period of time by placing 3 gems from their bank into each structure, after which their bank would replenish with 3 randomly generated gems. Players could either place 3 random gems to power the structure for a short time or match the gem type to the "recipe" shown on the structure to power the structure for a longer period, creating a larger effect for that structure. The level was completed when the player placed an adequate number of gem sequences to sufficiently power the defense structures to push back enemies and let the healing structures fully grow their tree. Players could earn 1, 2, or 3 stars depending on how quickly the level was completed, which contributed to the player's total score, representing the accumulated points earned across overall levels. The number of stars earned also corresponded with the amount of silver, which functioned as the in-game currency gained upon level completion.

The first 3 levels of the game served as tutorials with instructions about how to play, and they were designed to be easy to win to engage players early on. As the game continued, players were exposed to levels with progressing difficulty, which required more advanced defense structures and strategic decision-making to defeat the new enemies.

In addition to playing the levels of the core game, players could access a metasystem, which was an area for activities performed outside of the core game levels. All players had a village that they could customize in the metasystem. Silver was the primary currency, earned through core level completion, that could be used to purchase cosmetic additions to customize the village and upgrade the strength of the defensive and healing structures used in the core game. Village customization was for aesthetics only and served no functional purpose, but defensive and healing structure upgrades were critical to the players' progression through more challenging levels in the core game (see Figures 2A-2C for screenshots of each game component).

Figure 2. Screenshots of Inspire. (A) core game level, (B) core game level, (C) metasystem, (D) smoking report results, and (E) silver multiplier for passing smoking report (abstinence-contingent [AC] group).

Game use outcomes included the total numerical score achieved in the game, with higher numbers indicating higher game use and achievement in completing levels. The total number of stars earned was calculated by adding the 1, 2, or 3 stars granted for the completion of each level (including replayed levels). The highest level achieved in the game and days of gameplay were also reported. Finally, the total number of defense and healing structures built in the metasystem was summed.

The Game Addiction Scale [30] assessed for indicators of gaming addiction. A total of 9 questions from the problems, conflict, and relapse subscales were rated on a 5-point Likert scale and assessed during participant intake and week 7. Scores were summed to indicate a total score of game addiction, with higher scores denoting more frequently endorsed gaming-related addictive behaviors (range 9-45). The SC and the AC groups were compared on game use (ie, the highest level, total score, total number of stars, and total number of buildings) and game addiction total scores.

Smoking Self-Reports

As mentioned previously, players were told to submit a smoking self-report twice per day. These reports were separated by at least 8 hours and stated whether they had smoked since submitting their last report; if so, participants reported the number of cigarettes they had smoked [29]. Participants were sent push notifications that signaled when it was time to submit each report and the time by which the reports were due to avoid being recorded as “missed.”

Upon submission of each smoking self-report, the game displayed a bar graph showing the number of cigarettes reported in each prior submission so that the participants could track their smoking cessation progress over time (Figure 2D). Submission of each smoking self-report unlocked the next level in the core game system, regardless of self-reported smoking or abstinence. Therefore, players could unlock a maximum of 2 new levels per day. Participants could also replay any unlocked level as often as they liked to earn additional silver (ie, in-game currency).

Players earned in-game rewards for submitting a "passing" smoking self-report, the criteria for which depended on their group assignment (refer to the Study Phases in the Methods section). These rewards consisted of a gem prism and a silver multiplier. The gem prism was earned for every pass and could be used to select a gem color of their choice in the core game, which players could use to more easily meet the "recipes" required to power their defensive or healing structure for a longer period if their randomly generated gem bank had insufficient gems available for the recipe. Although players could match gems at random to power their structures for a shorter time, gem prisms earned through passes made fulfilling gem recipes easier, allowing for a longer structure activation and making completion of the level more likely. A silver multiplier was earned for submitting 3 consecutive passes and increased the amount of silver earned by each completed level in the core game. Multiplier values included 1×, 2×, 4×, or 7× and increased with every 3 consecutive passing smoke reports (Figure 2E). Larger quantities of silver earned through passing smoke reports could be used to more frequently upgrade the defensive and healing structures in the metasystem. This resulted in stronger structure performance, which was particularly important for later, more challenging levels.

Smoking self-report outcomes included the percentage of smoking self-reports submitted (out of the total requested reports over the course of gameplay) and the percentage of smoking self-reports indicating abstinence (out of the total submitted reports). The percentage of smoking self-reports indicating abstinence was determined for all reports throughout the gameplay and calculated for just the abstinence phase, where the goal for cigarette use was set to 0. The duration of the abstinence streak was calculated based on the highest number of consecutive reports of 0 cigarettes smoked throughout the study. The self-report submissions informed treatment dropout, which was based on the completion of each phase of the study (eg, baseline, tapering, abstinence, and thinning). Specifically, participants were scored as completing a phase if they submitted at least 1 smoking self-report in the final 2 days of the phase. The follow-up survey assessed whether participants continued to smoke once participation concluded (ie, 30 days after week 7). Participants were asked whether they had spent 24 hours without a cigarette in the previous 2 weeks and whether they had not taken a puff from a cigarette in the past 7 days. We compared the SC and the AC groups on all smoking cessation outcomes (ie, percentage of abstinent submissions during the abstinence phase and the longest duration of abstinence streak).

Game Use on Smoking Abstinence

The proposed analyses originally planned to compare the 2 study groups, SC and AC, in the relationship between game use and smoking abstinence. This would have tested whether in-game rewards for reporting smoking abstinence were more effective in promoting cessation than rewards for reporting smoking independent of meeting abstinence goals. However, we found no systematic differences between the groups on demographics, smoking history, game use, or self-reported abstinence. In this study, earning in-game rewards (submission only or meeting abstinence goals) did not seem to impact gameplay or cessation. Therefore, the 2 groups were combined into 1 analytical group for the remaining analyses.

A total of 2 gamma generalized linear models with a log link function were created to examine the impact of total game score and the highest level achieved on both the percentage of abstinent submissions during the abstinence phase and the longest duration of abstinence. The models were conducted both with and without an interaction term between the total game score and the highest level achieved to determine the necessity of its inclusion, using the Akaike Information Criterion, Bayesian Information Criterion, and Bayes Factor as selection criteria. A generalized linear model was used to account for data heteroscedasticity, and a gamma distribution was used to accommodate a positive skew on both models.

Cotinine Testing

Saliva cotinine testing was conducted at intake, week 2, week 4, week 7, and the 30-day follow-up to confirm smoking abstinence. Testing kits (NicAlert) [31] were mailed to all eligible participants to biologically verify self-reported tobacco use. If participants reported using cessation strategies that could elevate their cotinine levels (eg, nicotine replacement therapy or vaping nicotine), cotinine testing was not conducted. Once the kit was received, a member of the research team scheduled a video call to walk the participant through completing the test at home. After testing procedures were completed, participants submitted an image of the strip results to the researcher. A total of 2 observers independently scored all strip results and were unaware of the time point at which the test was conducted. The interobserver agreement was calculated by dividing the number of strip results agreed by the total number of strips obtained, multiplied by 100 to obtain a percentage. The interobserver agreement was 91.7% for all strip results. Participants who were eligible to submit cotinine samples received US $5 for each submission.
